Love.[6] Man, forty-three years of age. Severe diabetes for nine months. Several days after beginning a rigid diabetic diet there developed troublesome constipation, abdominal pain, mental confusion and slight headache. The urine was free from albumin. One evening patient had an "epileptic fit" lasting two and a half minutes and was afterward drowsy and had noisy breathing. Fifteen minutes later had a second general convulsion with deep unconsciousness. Immediately after this

there was furious mania and five minutes later a third convulsion. The convulsions were repeated almost continuously (forty-six in all) for twelve hours. Between attacks the patient was maniacal. These were followed by coma for a few hours and death. The urine just before death "gave a dubious acetone reaction (so-called) with perchloride of iron." Post-mortem "no gross lesion was found anywhere likely to be in any way associated with the diabetes or the convulsions."

Jacoby.[7] Girl of twenty-two years. Father had died of diabetes. Symptoms of diabetes for one year with severe double sciatica. For some weeks there had been also severe pain in arms and breasts, attacks of vomiting and constant diarrhea. The urine contained 2 per cent. of sugar and frequently also acetone. Patient then developed attacks of general convulsions, beginning in both arms and accompanied by loss of consciousness. Attacks were repeated from time to time for seven months. She then passed into a state of coma, and died five days later without further convulsions.

Redlich.[8] Man, thirty-five years old. Three weeks after onset of symptoms of severe diabetes he developed pains and stiffness in right leg and arm which became somewhat weak and showed from time to time "contractures." One week later he suddenly lost power of speech and began to have frequent convulsions of the affected side, associated with profuse flow of saliva. Consciousness was preserved in the attacks. During next two weeks the degree of hemiplegia and aphasia fluctuated from time to time. When seen there was motor aphasia, slight mental dullness and an acetone odor to breath. There was weakness of lower half of right side of face and of right arm and leg. Tongue not involved. Sensibility normal. Daily urine amounted to 7,000 c.c. and total sugar excreted to about 400 grams. Urine contained much acetone and diacetic acid but no β-oxybutyric acid and no albumin. The convulsions, which were very frequent, began with a deep, noisy inspiration and with a brief tonic cramp of the muscles of right side of face and neck. This was followed by clonic convulsions of right side of face, paw, neck, and arm. Towards end of attack there was a profuse flow of saliva. The paroxysms lasted about two minutes. During the four days in the hospital variations in the severity of the hemiplegia and the aphasia were readily appreciable. Patient became more stuporous, the convulsions became more frequent and severe, and death occurred in coma. The urine continued to show much acetone and diacetic acid. At autopsy the pancreas was normal. A very careful microscopical examination of brain showed nothing but marked injection of the larger and smaller blood-vessels.

Lossen.[9] Case I. Married woman, aged twenty-five years. Severe diabetes for at least several months. With great restriction of carbohydrates the sugar fell from 600 grams to 15 grams or less a day. With complete withholding of carbohydrates evidences of acetone, diacetic acid and β-oxybutyric acid appeared in the urine and a few days later there developed sudden blindness which was followed in a few hours by convulsions which were repeated at frequent intervals until her death, thirteen hours later. The attacks always began with twitchings of the left arm which were soon followed by a tonic spasm of this arm and later of the right arm and leg. This tonic cramp was in turn followed by severe clonic convulsions of all four extremities and of the face. The pupils were widely dilated and did not react to light. Consciousness was completely lost during the paroxysms and usually remained so during the short free intervals. Once, however, the patient regained consciousness, complained of severe headache, and asserted that she still could see nothing. Examination of the eyegrounds was negative. No appreciable loss of power in muscles of face or extremities. No disturbance of sensation. In one attack the twitchings began in the *right* arm instead of the left. At no time did the breathing present the features of the Kussmaul air-hunger. At the autopsy all the organs, including brain, pancreas, and kidneys were essentially normal.

Case II. Girl, sixteen years old. Severe diabetes for five months. Under very rigid dietary the sugar remained nearly or completely absent, but there was constantly in the urine acetone and diacetic acid and often some β-oxybutyric acid. With large doses of sodium bicarbonate the urine could be kept neutral or alkaline. Eventually there developed gradually the usual symptoms of threatening coma; headache, vomiting, typical air-hunger, acid urine, and an increased amount of oxybutyric acid. This condition continued for sixty hours without loss of consciousness. The patient then had several general convulsions with some return of consciousness in the free intervals. The convulsions began with a stage of tonic spasm followed by severe clonic convulsions of the entire body. Death occurred in coma some hours after the last convulsion. The autopsy showed extreme atrophy of the pancreas, normal brain, and kidneys.

Stauder.[10] An obese woman, fifty-three years old. Severe diabetes for two years. Daily urine 3 to 6 liters, sugar 4 to 6.6 per cent. No acetone nor diacetic acid, no albumin. Gradual improvement under treatment, then sudden appearance of attacks consisting of dizziness, headache, and twitchings of the left shoulder and arm. The convulsions began with a tonic stage in which the head and eyes were turned to the left, and left arm became rigid, and this was followed by violent trembling of the left arm. The face was not involved. Consciousness was lost for two or three minutes. Between the attacks there was some weakness of the left arm, some diminution in sensation in the upper arm and absence of the tendo Achilles reflexes. Otherwise the examination of the nervous system was negative. Thirteen such paroxysms occurred within a period of six days. Then under alkaline treatment there was gradual improvement with return of strength in the arm. Only once did the urine show traces of acetone and diabetic acid.

Soetbeer.[11] Patient was a man, twenty-seven years old, who suffered from severe diabetes with a large sugar excretion and with all the evidences of a severe acidosis (acetone, diacetic acid, β-oxybutyric acid, and a high ammonia nitrogen). During a period of eight days he had from three to thirteen convulsions daily. Some of these were distinctly Jacksonian in character, with clonic convulsions of right side of face, right arm, and leg; transient unconsciousness, and subsequent paresis of right side of face and right arm and leg with exaggeration of the knee jerk and a Babinski reflex. Others resembled those of true epilepsy, with a tonic stage followed by severe general clonic spasm, with biting of the tongue and with immobility of the pupils. Between the attacks there was constantly some slight weakness of the right side with persistence of Babinski's sign. The attacks usually lasted only a few minutes. Breathing shallow; no air-hunger; no coma. With the use of

large amounts of sodium bicarbonate the severity of the acidosis diminished, and the attacks ceased.

Later by stopping sodium bicarbonate and adhering to a rigid carbohydrate-free diet (with increasing acidosis) attempts were made (!) to excite a return of the convulsions, but without success. Patient eventually improved in weight and general condition and when discharged all evidences of paresis had disappeared, although sugar, acetone, and diacetic acid were still present. The urine gave no indication of a nephritis.

A study of these fourteen cases indicates that the epileptiform attacks of diabetes may, as a matter of convenience, be divided into three more or less distinct groups:

1. Attacks of general convulsions, not to be distinguished from those of true epilepsy, which begin usually with a short tonic stage and are associated with complete loss of consciousness, immobility of the pupils and, often, biting of the tongue.

2. Attacks marked by convulsions beginning in a single group of muscles, but spreading rapidly to other groups until a general convulsion results. In this group also consciousness is lost.

3. Attacks of typical Jacksonian epilepsy, with convulsions restricted to single groups of muscles or to one side of the body; associated usually with other symptoms of focal brain disturbances and with no loss of consciousness.

Five of the cases belonged to the first group. In three of these (Scheube, Love, Lossen, Case II) the attacks appeared only in the last twenty-four hours of life and were a part of the terminal coma. In Jacoby's case the convulsions occurred from time to time over a period of seven months and were absent in the final coma. In Lépine's patient there was a general convulsion on two successive days and then an interval of several days before the fatal coma manifested itself.

Two instances occurred of the second type of convulsions (Kraus, Lossen, Case I). In both the attacks began in the left arm. In Lossen's case the convulsions were a part of the terminal coma. In that of Kraus, after occurring at frequent intervals for a number of days they gradually ceased entirely.

The third group of cases is of much the greatest clinical interest because of their striking resemblance to cases of focal organic disease of the brain. Seven of the above cases belong to this group. In five of these (Abbe, Lépine and Blanc, Redlich, Soetbeer, and myself) the right half of the body was involved. In Dr. Johnston's case the convulsions were limited to the right half of the tongue and face; in Stauder's case they affected the left side of face and left shoulder and arm. In all of these cases there was, to a greater or less degree, paralysis of the affected muscles. In some the hemiplegia was pronounced and permanent. Three of the right-sided cases showed distinct aphasia. In several of the cases, also, sensory disturbances in the affected parts were noticed (pain, numbness, anesthesia).

The length of time over which the convulsive attacks extended and the total number of convulsions, varied within very wide limits. In Jacoby's case the attacks appeared only occasionally over a period of seven months. In my own case they occurred at least several times a day during a period of five weeks. In several instances they appeared only in the last twenty-four hours of life. In eleven of the fourteen cases the epileptiform attacks were followed, sooner or later, by coma and death. In the remaining three cases the convulsions, after lasting for a few days, ceased with improvement in the other symptoms.

The convulsive attacks were sometimes associated with various other cerebral symptoms. Severe headache frequently preceded and followed the convulsions. Somnolence was present in several instances. Sudden amaurotic blindness preceded the initial convulsion in one of Lossen's cases. Lépine's patient had visual hallucinations. In one case (Love) there were maniacal outbreaks between the convulsions; in another (Redlich) each convulsive attack was accompanied by a profuse flow of saliva.

Autopsies were made in seven of the eleven fatal cases. In none of these did the brain show gross changes and in only one were there discoverable histological changes. In this case (Lépine and Blanc) microscopical examination showed atrophy and disappearance of many of the cortical cells of the motor area of the side opposite to that in which the convulsions occurred and which had been hemiplegic for six weeks.

In seeking for an explanation of the cause and nature of epileptiform attacks in diabetes it is obvious that they must be considered in relation to the various other affections of the nervous system which often play such an important part in the clinical picture of the disease. The frequent occurrence of local neuralgias or neuritides, the frequent loss of the tendon reflexes, the cases of pseudo-tabes and those rare cases of hemiplegia without convulsions and without discoverable changes in the brain all seem to point to the existence of some poison with a special affinity for the delicate nervous tissues. The absence of any histological change in the brain in most of the cases collected here is in accord with the results of the examination of the cord[12] and of the peripheral nerves[13] in certain cases giving well marked symptoms referable to these structures. Whatever the cause it is evident that it may produce grave disturbance of the functions of the nerve cells over a considerable period of time and yet produce in them changes too subtle to be detected by the most careful histological examination. As to the nature of this neurotoxic agent, we are still altogether in the dark. It is conceivable that these nervous manifestations might depend merely upon the abstraction of some nutritive substance from the nerve cells in the progress of the general malnutrition which characterizes the severer forms of diabetes; but such an explanation seems highly improbable. Such manifestations are not common to other forms of malnutrition.* nor are they found only in cases of diabetes with marked emaciation. In my own case the patient's general nutrition was excellent and the picture was not at all that of a severe diabetes.

It seems much more likely that the nervous symptoms result from the action of some active poison formed in the course of the abnormal metabolic processes which go to make up the disease.

The almost constant association of marked acidosis with the usual and characteristic type of diabetic coma—that in which the "grosse Athmung" of Kussmaul is the most distinctive feature—leads one, naturally, to inquire into the relation of such acidosis to the occurrence of epileptiform attacks. In reviewing the cases cited here one cannot but

*Rare exceptions to this rule have, however, been recorded in the cachexia of pulmonary tuberculosis by Senator (*Berl. klin. Woch.*, 1879), and in that of cancer by Oppenheim (Charité Annalen, 13 Jahrg. 1886).

be struck with the inconstancy of this feature. In only three cases (Lossen, Soetbeer) is it certain from the description that a severe acid intoxication existed. In several of the cases no conclusions can safely be formed upon this point; but in at least three instances (Kraus, Stauder, Conner) it is certain that no severe acidosis was present. In the case of Kraus not only did the urine contain no acetone bodies, but a careful study of the alkalescence of the blood showed no departure from the normal. In several other cases the evidence, as far as it goes, points to an absence of severe acidosis.

In Soetbeer's patient, although the convulsions were associated with much acidosis and ceased as the acidosis was diminished by a more liberal diet and by the use of alkalies, they did not return when the acidosis was increased by a temporary cessation of the treatment.

The character of the final coma, also, was by no means constant. In several instances it is described as having been of the typical Kussmaul type. In several other cases, including my own, there was at no time the characteristic deep breathing or air-hunger. This inconstancy of the signs of acid intoxication (including the Kussmaul type of coma) in these cases makes it very unlikely that either the acidosis itself or any one of the substances directly associated with it is the immediate and direct cause of the convulsions.

It is interesting to note the close resemblance of many of the nervous symptoms of these cases to those of uremia. The general convulsions, the Jacksonian attacks, the transient paralyses, the amaurotic blindness, the severe headaches, the maniacal attacks, the respiratory disturbances, the coma—all these find their counterparts in uremia. Yet the symptoms in these cases were certainly not due to uremia. There is abundant clinical and post-mortem evidence to disprove such a view. All that can be said is that the unknown poison of uremia and that of certain cases of diabetes may produce severe and strikingly similar disturbances of the central nervous system, without there being, in either case, demonstrable anatomical changes.

Summary.—Although some of the epileptiform attacks which occur in the course of diabetes are manifestly due to other associated conditions (uremia, cerebral softening, meningitis, etc.), a certain proportion of them are unquestionably related directly to the diabetes itself and are the expression of some form of diabetic intoxication. Such attacks may simulate closely the general convulsions of true epilepsy, or they may be distinctly Jacksonian in character and be limited to one side of the body or to certain groups of muscles. These localized convulsions are usually associated with transient paralysis of the affected muscles, aphasia, sensory disturbances, or other symptoms suggestive of a circumscribed brain lesion, and may thus lead to serious errors in diagnosis.

The convulsions may appear only during the terminal coma, or they may be repeated at frequent intervals for days or weeks before coma develops, or finally, they may cease with improvement of the diabetic symptoms.

The association of such epileptiform attacks with the signs of acid intoxication is by no means constant. In several of the cases it is certain that no such acidosis existed. It seems probable, therefore, that the cause of the convulsive attacks must be sought for in some other form of diabetic intoxication.

THE SURGICAL TREATMENT OF ALVEOLAR PULMONARY EMPHYSEMA.*

By CHARLES GOODMAN, M.D.,

NEW YORK.

ADJUNCT VISITING SURGEON, BETH ISRAEL HOSPITAL; ADJUNCT ATTENDING SURGEON, MONTEFIORE HOME; CHIEF, SURGICAL DEPARTMENT OF MOUNT SINAI HOSPITAL DISPENSARY.

AND

SIEGFRIED WACHSMANN, M.D.,

NEW YORK.

CHIEF OF RESIDENT STAFF OF MONTEFIORE HOME.

Within the last decade a number of diseases with obscure pathological conditions have been cleared up and rendered amenable to treatment by rational surgical procedures. Judging from the results thus far obtained, some of the obstinate forms of emphysema bid fair in the near future to be classed as surgical diseases which are amenable to operation.

As a result of studies begun by him fifty years ago, A. W. Freund[1] of Berlin contended that the abnormal arrest in the development and the consequent shortening of the costal cartilage of the first rib, combined with the resultant narrowing of the superior strait of the chest, were important anatomical predisposing factors in tuberculous infection of the apex of the lung. This led him to advance the theory that a correction of this condition in flat-chested individuals was a rational procedure as both a prophylactic measure and a potent curative measure in the incipient stages of this disease.

This recommendation by Freund, has not, up to the present time, been carried out by anyone, to our knowledge, although the pathological findings enumerated have been confirmed by several other investigators. Among these may be mentioned Hart, Schmorl, Birch-Hirschfeld, Hansemann and others.

These remarks are, however, but an introduction to the topic for discussion this evening upon the practical deductions made by Freund from the pathological findings in the costal cartilages, so

*Read at a meeting of the Section on Medicine of the New York Academy of Medicine, April 21, 1908.

graphically described by him as the real cause of pulmonary emphysema. In other words, the generally accepted theory that the barrel-shaped chest in certain forms of emphysema is caused by the condition of the lungs has been long combated by him. He claims and proves that the reverse is true. He has constantly asserted that the rigidity of the chest due to the pathological changes in the ribs and the costal cartilages were the forerunners of the changes in the lungs which are associated with the symptom-complex recognized clinically as pulmonary emphysema.

The pathological findings described are as follows: the costal cartilages are of a dirty yellow color, in a state of fibrillation and cystic, showing also calcareous deposits which cause them to become increased in size. They are hardened, brittle and devoid of their normal elasticity.

In the presence of the foregoing changes, the proper excursion or motion of the corresponding ribs is interfered with. The cartilages of the second and third ribs of the right side are most frequently involved, but these changes may involve all the costal cartilages. The first cartilage, however, is rarely, and then usually the last, to be involved in this disease. With the degeneration of the cartilages and the accompanying rigidity of the ribs, the sternum is forced outwards and contributes eventually to the formation of the rigid barrel-shaped thorax, which retains the lung in a continued state of distention. With the increase in the diameters of the chest, the normal function of the diaphragm is interfered with and the muscle shows evidences of atrophy and fatty degeneration.

By removing or resecting the offending cartilages, the proper functioning power of the chest may be restored; the ribs will be permitted to exercise their proper range of motion, and the proper expiratory efforts of the lungs will be facilitated.

Whether this hypothesis of Freund is tenable or not, the future will decide, and is left to your judgment from the recital of cases which have been reported; to these the writers will add their experiences on four cases which were operated upon recently at the Montefiore Home.

Case I.—Patient of F. Kraus. Carpenter, aged forty-six years, with emphysema of two years' standing, following pneumonia. Since then he complains of dyspnea, cough, palpitation, and profuse expectoration, which have resisted all forms of treatment. Is troubled with insomnia and unable to lie down in bed.

Examination.—Barrel-shaped chest, with characteristic physical signs of alveolar emphysema. Chest expansion only 2 cm. The apex impulse of the heart is at the sixth space. The arteries are hard and tortuous. The liver is enlarged and pushed downwards. The spleen is also enlarged. Lower extremities edematous. Albuminuria with hyaline casts and renal epithelium.

Operation March 8 by O. Hildebrand. Schleich infiltration anesthetic was used on account of marked cyanotic appearance of the patient. The second and third costal cartilages were resected on the right side, and this was followed by normal excursion of the corresponding ribs. On account of pain, further operative procedures were discontinued.

The day following the resection, the patient for the first time in many months was able to assume a comfortable recumbent posture in bed. The cartilages removed showed the characteristic changes described by Freund.

April 24. General anesthesia being administered, the second, third, and fourth cartilages of left side were resected. The patient was discharged May 16, when the following was noted: Chest expansion 5 cm.; increased three months later to 7 cm. Vital capacity of lungs increased from 800 to 1,400 c.c. Chest not so barrel-shaped. Radioscopic examination shows ribs functionating properly. Cyanosis has entirely disappeared. The albuminuria is diminished. The patient feels decidedly improved.

Hildebrand in his concluding remarks upon the case mentions the unlikelihood of the regeneration of the resected cartilages. But this was not our experience in the first case operated upon (Case IV in this report). The cartilages reformed within five weeks and caused a return of the former symptoms.

Case II.—Mohr-Bramann-Haasler. Glazier, age forty-six, troubled with dyspnea for five years. Rigid chest, with very shallow respiration, costal cartilage from the second to the fifth, both sides very much thickened. Bronchitis with expectoration. Sputum negative as to asthma and tuberculosis. Coarse and musical râles both sides.

Arteriosclerosis. Heart negative. Urine negative.

April 15, 1907, Dr. Haasler resected 1½ cm. of the second and third costal cartilages on the right side. This was followed by decided relief of dyspnea which lasted about a month, when the patient again experienced more or less difficulty in breathing and had a troublesome cough; he returned to the hospital for operation on the left side.

May 29, 1907. Dr. Bramann resected a portion of the second, third, fourth, and fifth cartilages on the left side. The resection was followed by an immediate falling in of the chest wall with retraction of the lung during expiration. General relief of the symptoms, and chest expansion increased to 5 cm. at the end of one month. At time of report, July, 1907, the patient had so far had no return of former symptoms.

Case III.—Passler and Seidel. Laborer, aged fifty years. History of rheumatism in early life and two attacks of diphtheria with myocarditis several years ago. Troubled for the last five years with marked dyspnea on the slightest exertion. After climbing one flight of stairs, the patient would be obliged to lie down for fifteen minutes before obtaining relief.

Examination.—Barrel-shaped, rigid chest, with expansion 2 cm. Dyspnea and cyanosis upon the slightest exertion. All the classical signs of an uncomplicated emphysema.

Operation June 6, 1907, by Dr. Seidel. Chloroform anesthesia. The first five costal cartilages on the right side were resected to the extent of 1¼ to 2 cm. This was followed by an immediate shifting of the lung and distinct movement of the heretofore fixed and rigid ribs. The vital capacity of the chest increased from 1,200 to 2,700 cc. in the five weeks following operation. When discharged July 13, the man showed decided flattening of right side of chest. The patient was able to climb three stories without the slightest difficulty in breathing and has returned to his former occupation.

Case IV.—C. A., German. Bartender, age forty-one, has been troubled with dyspnea for almost eight years, and on account of frequent, almost daily, attacks of asthma has been unable to work for about five years. He has had all forms and sorts of treatment, including *x*-ray, without affording him relief. Examination showed a rigid, barrel-shaped chest with classical physical signs of em-

physema and asthma. Slight arteriosclerosis. Marked dyspnea and cyanosis upon the slightest exertion. Heart action weak. No murmurs. Expectoration abundant, but tubercle bacilli are absent.

On October 15, 1907, under local anesthesia, we succeeded in resecting the second costal cartilage on the right side. The patient complained of pain and was so troubled with asthmatic seizures that general anesthesia was substituted. The third and fourth cartilages were then resected for about 2 cm. and the wound was closed with the exception of a small rubber drain.

The second night following the operation the patient slept uninterruptedly from 10 P. M. to 5 A. M. without medicine, for the first time in several years. Cough and expectoration gradually diminished and almost entirely disappeared. Edema of the lower extremities set in about a week after operation, but disappeared again in the course of several days. This patient felt otherwise very comfortable for almost five weeks when asthmatic seizures again made their appearance. Examination of the chest showed that expansion had diminished to the former shallowness. The ribs had again resumed their former rigid consistency owing to reformation of the resected cartilages. The patient enjoyed such decided relief during the few weeks following his operation that he has consented to submit to a second operation, which will be undertaken in the near future.

Case V.—J. J., painter, age fifty. Admitted to Montefiore Home December 17, 1907. He had enjoyed good health until 18 months ago, but since then has had frequent asthmatic attacks, sometimes as often as three times a day, for which various remedies have been tried with but little temporary relief. Within the last six months he has used 80 ounce vials of adrenalin chloride hypodermically in efforts to obtain relief of his dyspnea. He is unable to perform any kind of work.

Examination.—Upper extremities covered with pigmented scars, the site of hypodermic medication. Superficial veins are markedly dilated; finger tips and mucous membranes cyanotic. Very marked dypsnea. All the accessory muscles of respiration are hypertrophied. Respiration is shallow, chest rigid, showing very little lateral expansion.

March 10, 1908, ether and chloroform being given, the third, fourth and fifth cartilage of the right side was resected for about 2 cm. *together with the perichondrium* with a view of preventing recurrence of our experience in the first case. Third night following operation the patient was able to sleep quite comfortably; cyanosis disappeared; cough somewhat improved. Chest expansion was increased from less than 2 cm. to 5 cm.

With a view of finding a method of operating, to avoid the reformation of the resected cartilages, we devised the following technique from studies made on the cadaver. After removing two or three centimeters of the costal cartilage and its overlying perichondrium, the remaining posterior layer of perichondrium is carefully dissected up from its attachments and reflected over the stump of the resected rib, where one or two sutures of chromicized gut retain it in place. This affords a smooth, riding surface for the resected rib, and with the interposed sheath of perichondrium there should be no possible chance of the rib again becoming fixed and functionless at this point. This operation we have been able to perform in three of our cases.

April 6, 1908. Patient J. J. was again anesthetized and the right second and left second and third cartilages were resected with the anterior perichondrium; the posterior layer of perichondrium was then dissected from its attachments and reflected over the stump of the corresponding rib where it was fastened with one or two sutures of chromic gut. The wounds were closed without drainage. Since the operation the patient has slept better, the cough is relieved, and the cyanosis has disappeared. Chest expansion has increased to 6 cm. Two weeks after operation the patient walked eighteen of our city blocks and back, returning without being fatigued, but during the following night he had some dyspnea, most likely due to overexertion of his heart. If the dyspnea had been of thoracic origin it would have appeared during the exercise. This is what usually happened before the operation. With chest expansion increased to 6 cm. the vital capacity, before the second operation, 1,800 c.c., has increased to 2,700 c.c.

Case VI.—H. W., age fifty-two. Driver. Admitted to Montefiore Home four years ago. During this time he has been troubled with cough, frequent attacks of dyspnea, followed by exhaustion.

Examination.—Thorax wide and deep, with physical signs of emphysema. Superficial veins very prominent. Face cyanotic, conjunctivæ injected. Chest expansion 2 cm.

March 31, 1908. Chloroform and ether anesthesia was given by Dr. C. J. Pick. The second, third, and fourth cartilages on the right side were resected. The perichondrium was reflected over the end of the rib and fastened as in the preceding case. The wound was closed without drainage. The patient experienced some pain in the region of the wound for two days. On the fifth night he slept uninterruptedly without medication all night. This patient shows decided improvement since being operated upon, and with the exception of two slight asthmatic attacks, he has felt quite comfortable.

Case VII.—M. S., aged fifty-two, tailor. He has complained of cough and dyspnea for over fifteen years. Cannot walk two hundred feet without suffering from air hunger and cyanosis.

Examination.—Emphysema with classical rigid barrel-shaped thorax, without movement of the ribs during respiration. Marked cyanosis of mucous membranes and finger tips. Arteriosclerosis and albuminuria. Sputum does not show tubercle bacilli. Operation, April 14, 1908, chloroform and ether. The second, third, and fourth costal cartilages on the right side, and the left second and third, were resected, and the perichondrium was treated as in the preceding cases. No drainage was employed. On the fourth day the patient, sitting on the edge of his bed, bent down to pick up something from the floor. He states that such an attempt before his operation would have caused him to choke. His former chest expansion 2 cm., has increased to 5 cm., and his vital capacity has also increased from 1,000 to 1,900 c.c. The usual vertical elevation of the thorax *in toto* with each respiration has almost entirely disappeared. The cartilages removed in our cases (IV., V., VI., and VII) were examined by the pathologist, Dr. D. M. Kaplan, who found in them the characteristic changes described originally by Freund, including evidences in them of calcareous deposits, and also showing areas of ossification.

Since the above was written we have found two more cases reported.

Case VIII.—Stieda of Halle resected 2-3 cm. of the right and left second, third and fourth cartilages in a patient with chronic emphysema with marked rigidity of the thorax. The condition of

his patient was decidely improved by the operation.

Case IX.—M. Cohen of Berlin. His patient, aged forty-five years, had chronic pulmonary emphysema which had resisted all forms of treatment. He resected the second, third, fourth, and fifth cartilages on the right side. The result as reported by him, was as follows: After the operation, the patient was able to lie down. This he had been unable to do for many months prior to the operation. The dyspnea, palpitation, and cyanosis were decidedly diminished. The chest expansion increased from 1 cm. to 5 cm.

It is of great interest to note that both of these surgeons also recognized the importance of taking measures to prevent the reformation of the resected cartilages, and in these cases they excised the perichondrium.

From the nature of the operation it is self-evident that only mechanical treatment is intended. Aside from air chambers, the mechanical treatment so far has consisted in rhythmical manual compression of the thorax as recommended by Gerhardt and others, or various breathing chairs, either manipulated by the hands of the patient, or, as in the Zander apparatus, by the aid of machinery. Natural compression of the chest can only be brought about when the ribs are movable. One symptom constant in emphysema is the rigidity of the thorax, preventing both compression and expansion to the same degree. Whether or no this rigidity is the cause of emphysema is immaterial; it certainly is a distressing symptom and stands in the way of a cure. Whatever is left of elasticity or contractile substance in the lung tissue cannot functionate so long as the chest walls are rigid; the visceral pleura cannot leave the parietal because a vacuum would be created and the lung would again return to a state of distention.

As to the pathological changes in the costal cartilages which are said to be normal at the age of fifty, there must be a difference in degree, otherwise we would not have a movable thorax in normal individuals, and the rigid thorax in emphysema.

Having freed the ribs, we are aiding nature toward a spontaneous cure, permitting the lung to contract, an object which all previous methods of mechanical treatment have failed to accomplish.

It is possible that the operation is not a cure in itself, but the beginning of a cure, and it cannot be expected that the pathological changes in the lung tissue, in the bronchial membranes, and in the myocardium, which took years to develop, should disappear in a few weeks. But the possibility is afforded through the restoration of the mobility of the thoracic walls.

From our experience thus far with the operative treatment of pulmonary emphysema, we have come to the following conclusions:

1. Freund's operation is of great benefit in emphysema with a rigid dilated condition of the thorax.

2. A most convincing feature of this treatment is observed during operation; when the costal cartilage is resected the rib recedes immediately, at times below the level of the sternum.

3. The ribs move so freely that the finger tip is distinctly squeezed when inserted between the sternum and rib.

4. The lung visibly contracts.

5. Relief may be afforded by operating upon one side.

6. The operation is not dangerous, and is not followed by shock.

7. Cardiac insufficiency, asthma, chronic bronchitis, and albuminuria are not necessarily contraindications of the operation.

8. The best results are likely to follow, however, when the operation is undertaken before complications have arisen.

9. A removal of, or a plastic operation on, the perichondrium of the resected cartilages seems imperative in order to obtain lasting improvement.

In conclusion, the following fact may be noted which is of no scientific value but is worthy of note as an indication of the patient's view of the operation. The inmates of Montefiore Home were never known to be anxious to submit to an operation. If, within a few weeks, four patients for the same complaint voluntarily submit to this surgical treatment it tends to show that the patients consider the result of the operation a success.

A PLEA FOR STRICTER PROPHYLAXIS AND MORE SCIENTIFIC MANAGEMENT OF OBSTETRICAL CASES IN TENEMENT HOUSE PRACTICE.*

By E. K. BROWD, M.D.,

NEW YORK.

ATTENDING GYNECOLOGIST TO ST. MARK'S AND YORKVILLE HOSPITALS; ASSISTANT CHIEF TO THE GYNECOLOGICAL DEPARTMENT, GERMAN POLYCLINIC.

Licht, mehr Licht!
—*Goethe.*

While the percentage of maternal and infantile mortality in obstetric cases has been of late considerably reduced in our lying-in-hospitals, it continues to be high in private practice, especially among the poorer classes. Individual statistics are unreliable, and the existing high mortality and morbidity rate is consequently below the true figures. The most recent scientific researches indicate the newest and best methods for the care of the pregnant woman, and give elaborate details for ante-partum preparations, such as measurements of the pelvis, examination of the heart, lungs, viscera, urethra, bladder, and nervous system. Clinical pathologists urge the necessity of making antepartum examination of the blood, number and character of the red corpuscles, number of leucocytes, differential count, amount of hemoglobin, etc., as means of forecasting of a possible secondary anemia of pregnancy. They suggest examination of feces with a view of determining the presence of bacteria which may favor intestinal toxemia; repeated microscopical examinations of the urine for

*Read in part at a meeting of East Side Physicians' Association, February 21, 1908.

albumin, casts, urea, as a safeguard against faulty metabolism leading to eclampsia, sepsis, etc., and they even advise examinations of the gastric contents as a preventive diagnostic measure.

Our methods of prophylaxis applied to the lying-in woman of the poorer class falls short of this scientific mark, and she is very frequently left to the mercy of the ignorant midwife. The prevalent idea of a confinement as being a natural physiological act is responsible for this indifference of the puerperal woman and she seldom consults a physician prior to the actual time of labor.

Thus the existence of malformations of the pelvis, the presence of fibroid tumors or ovarian cysts, a malposition, or the like, is detected only during actual labor. A thorough clinical examination is seldom if ever made, and existing lues, gonorrhea, valvular lesion of the heart, tuberculosis, or other disease leading to impairment of the constitution is frequently overlooked. The danger of such an omission is quite obvious and many a puerperal woman falls a victim to this neglect of prophylaxis. The time honored "non nocere" is too strongly adhered to and its application in abnormal cases has been productive of mishaps and unnecessary loss of lives. In normal cases accouchement forcé is always contraindicated. No amount of instrumental or manual skill can replace the wise mechanical methods of nature, in the gradual dilatation of the uterus by the dynamic force of the liquor amnii or the rotation of the fetal head. The premature application of forceps in the rigid cervix to the disengaged head or in the wrong axis of the pelvis is another violation of the natural forces, and may cause injury to the uterus or fetal head. But a malformation of the pelvis, a malpresentation or any deviation from the normal state is a pathological condition and must be dealt with as such; in such cases, procrastination is equal to the danger of expediting delivery in normal cases.

Given a case of transverse, face, or brow presentation in a primigravida with a small pelvis, labor extending over sixteen hours, with ruptured membranes for six hours, prolapse of funis, and the woman exhausted after tedious and dry labor. Under these circumstances, podalic version might endanger the life of the child, and might cause rupture of the uterus. How much less dangerous would this operation prove, if conditions had been ascertained earlier and the necessary assistance and anesthesia procured in time.

Picture again, in the case of a primipara, with a previously unrecognized rachitic pelvis of less than three inches in the conjugate, a full term child, a protracted labor of eighteen hours, with rupture of membranes since six hours, also presenting dystocia, anemia, exhaustion, and a partially septic condition. Craniotomy might cause the death of the exhausted woman and removal to hospital for a cesarean section might be impracticable or too late.

Imagine that you are called to a midwife's case of eclampsia in a tenement house. The woman is dying with her child *in utero* and you ascertain that a physician was never consulted before, nor was the patient's urine ever examined. In the few reports cited below, I have attempted to illustrate the great necessity of timely antepartum prophylaxis.

Case I. Rosa S., Hungarian, 31 years old, married fourteen years, has had eight children. Internal conjugate measures less than three and one-half inches. Her first child is small and alive after a normal birth. Her second child required craniotomy, which was performed by Prof. Taufer of Budapest. Her third and fourth children were craniotomized in Prof. Taufer's clinic. The woman has persistently refused to submit to cesarean section or premature delivery. She at last consented to the premature delivery of her fifth child, in the first week in the ninth month at the Lying-in Hospital, with the result of giving birth to a living child. In the case of the sixth child, the same procedure was resorted to at the Lying-in Hospital, with the result of a dead child. The seventh child lay in the transverse position. After internal podalic version, the child was born dead. I first made the acquaintance of this woman at the eighth confinement. When I arrived at her house, I found a midwife in charge. There was full dilatation of the uterus, also a prolapse of one arm into the vagina, and a prolapse of the funis which had ceased pulsating. Internal podalic version was done and the child was born dead. She became pregnant with her ninth child and engaged my services. I insisted upon cesarean section, or a delivery in the thirty-sixth week, but my advice was rejected. I then insisted upon being called at the beginning of labor, but was summoned two hours later, when the bag of waters had just ruptured. I found a vertex presentation; I did an internal podalic version, and there was considerable difficulty in extracting the head. The child was born alive but was considerably bruised, and bleeding from the mouth: the result of the forced extraction. The child only lived five hours. The woman rallied the next day and recovered. This case illustrates the result of neglect of prophylaxis on the part of the woman with considerable loss of fetal life.

Case II. Dora G., of Russian birth, 25 years old. She had a normal pelvis and pendulous abdomen; married four years; had two children. Her first child was delivered by forceps, still-born. At the second confinement, she was booked for the Lying-in Hospital, and upon her arrival, the bag of waters ruptured. She had a transverse presentation and a prolapse of funis. Anesthesia was given and an internal podalic version performed, with a child still-born. She engaged my services for her third confinement. Transverse presentation was found on examination. I insisted upon being called at an early stage of labor, with which patient complied. Upon my arrival, I found a finger's dilatation, the bag of waters intact, and strong labor pains. I summoned assistance and prepared for version. After the os was considerably dilated and the woman on the table in Trendelenburg posture, I ruptured the bag of waters and performed podalic version. The child was born alive and the woman was left in good shape.

Case III. Ida L., Russian, 31 years old, multigravida, normal pelvis, first three deliveries normal. At her fourth confinement she was attended by a physician who informed the family that the child was presenting with the head, but the navel string was prolapsed. He delivered her alone, without anesthesia, but the child was still-born. At her fifth labor, I was called about midnight and found the head partially presenting at the cervix which was dilated to a size of less than two fingers. Her labor pains were strong and regular. At 6 A. M. the os was fully dilated, and the bag of waters suddenly ruptured with a gush. The vertex changed rapidly into a face presentation and the umbilical cord slipped out of the os. She was placed in the knee-chest posture. I sent for assistance, and an internal podalic version was done. The child was born alive. The woman recovered.

Case IV. I was called by Dr. Sundelson to see the patient of a midwife, who had been at the bedside for nearly five hours. I found a multigravida with the bag of waters ruptured four hours previously. There was a complete prolapse of the left arm, with a prolapse of the cord. The child was still living. The woman was hurriedly placed in Trendelenburg posture. No anesthesia was given for lack of time. A difficult, but careful reposition of arm and navel string was first accomplished, and an internal podalic version done. There was great danger of rupturing the uterus. The child was resuscitated and the mother made a good recovery.

Case V. I was called by Dr. Dorfman to see a similar case in charge of a midwife, who had been in attendance all night. I found a prolapse of the arm and funis, with no pulsation of the cord. The child was dead. After great difficulty in replacing of the arm and funis, an internal podalic version was done. No rupture of uterus. Woman was left in good shape.

Case VI. Elonora N., born in the United States, twenty-seven years old, married seven years, III-gravida. She had had several miscarriages, which she admitted having brought on herself; she was a frail, anemic woman. When I was summoned to her, on a hot August night, she had been about two hours in labor. The os admitted two fingers, and she had a normal pelvis. The vertex presented, and the waters were intact. The pains were slight but regular, and I decided to wait for a normal delivery. The woman suddenly complained of feeling dizzy and had fainting spells. Her pulse counted one hundred and twenty-six and there was a slight elevation of temperature. I put the patient to bed. Stimulants were given with strychnine hypodermically. As no valvular lesion or uterine bleeding was present, the condition was ascribed to anemia, due to the intense summer heat. As labor pains and dilatation of os were proceeding, there was a sudden gush of the bag of waters and big clots of dark blood rolled out of the vagina. The head descended and I did a tamponage of the vagina. When assistance arrived, I rapidly delivered the child with forceps. No anesthetic was given. The placenta was found attached to a short umbilical cord and lay loose in the vagina. This was a case of premature separation of placenta, due to a short umbilical cord. The woman was in collapse from loss of blood. Credé's massage of the uterus and hot intrauterine douches were resorted to, also saline enemas and stimulation. The woman made a good recovery with a living child. The above conditions could not have been recognized prior to the rupture of the bag of waters, and it was surely due to timely assistance that her life was saved.

Case VII. Mrs. L., Hungarian, 22 years old, II-para, married four years, had one child three years ago. She had a normal pelvis, as well as a mitral lesion of the heart and dilatation with chronic bronchitis, emphysema, and chronic nephritis. She was pregnant five months, and was in a pitiful condition from want of air, as she had to sleep in the prone position. She was cyanotic with blue lips and finger nails. Her temperature was 102° to 103° and her pulse counted 126. I decided to perform accouchement forcé. No anesthetic was given; dilatation of os was accomplished by Champetier de Ribes bags, and internal podalic version was done. The patient rallied. Pregnancy in such a woman might well have been the cause of death. Such a woman is unfit for child bearing.

Case VIII. Mrs. R., Russian, young woman, I-para. This was a similar case of a woman suffering from a valvular lesion of heart and cardiac dilatation, emphysema, chronic bronchitis, and nephritis. Several physicians refused to attend her in confinement. She had a normal pelvis, the vertex presented and confinement was normal, but the patient caused me anxiety at the time of labor on account of her heart. She made a tolerable good recovery but was unable to nurse her child. She is still an invalid and entirely unfit for marital life. Her child is alive but sickly.

Case IX. Mrs. L., multigravida. Had had four children with normal births, and was now a V-para. She had a normal pelvis. Two months prior to her delivery she complained of a vaginal discharge with itching and burning during urination. She had been subjected to a digital examination by a physician, but a careful examination of the urethra was not made. A wash was ordered and the condition was not deemed to be serious. After the delivery the child developed gonorrheal ophthalmia, which was treated heroically, but the lesion was so severe as to result in the loss of the infant's eye. The mother passed through a normal labor, but two months later developed a double pyosalpinx for which a double salpingo-oophorectomy was performed. She made a good recovery and passed into artificial menopause. This woman is still constantly ailing, and is not nursing her child.

Case X. I was summoned in a great hurry to a woman in labor. I found a primipara. Upon my arrival she was in a state of eclampsia, and before any help could be given the woman died with her child *in utero*. I ascertained later that she never consulted a physician before nor was her urine ever examined. Inspection showed a very extensive edema of the lower extremities.

Case XI. Mrs. S., Austrian, in the care of a midwife, twenty years old, I-para, case of congenital hip-joint disease, scoliorachitis pelvis, measuring less than three inches in the true conjugate, vertex presentation, full term child. The woman was in labor twenty-four hours. The bag of waters had ruptured five hours previously. There was dystocia, exhaustion, accelerated pulse, elevation of temperature, and a partially septic condition. It was too late to send her to the hospital for cesarean section, hence a craniotomy was performed, and the woman was left in a precarious state. By request of the family she was sent to the Lying-in Hospital the next day, where she died the same night.

Case XII. I was called by Dr. Schechter to see a woman in labor, III-para, age twenty-four. Previous two labors were normal but tedious. The woman was a hunchback and a dwarf; she measured fifty-two inches in height; her pelvis measured three and one-quarter inches in the conjugate. At seven o'clock in the morning the woman was doing her housework, and also went to the store while her labor pains were in progress. One half hour later, while on the toilet, she felt the bag of waters rupture with a gush and something fall out. She then sent for her physician, but continued to do her housework. Upon my arrival, I found a descended occiput pressing upon four coils of a prolapsed and nonpulsating umbilical cord, right below the pubic arch and the child dead *in utero*. After cutting the cord between two ligatures, I applied the forceps but was unable to deliver the child. Craniotomy being impracticable, I did, under anesthesia, an internal podalic version and extracted the child. The woman made a good

recovery. This poor patient presented a type of a tenement house lying-in woman, who was performing hard labor up to the very time of delivery. Not a nurse around, neither before nor after delivery, no warm water in the house, no clean clothes; asepsis in such cases is impossible. The husband was at work and the woman was cared for by neighbors. Case of "misery," "poverty," "hunger," and "dirt." What a sad mockery of obstetrical prophylaxis of the poor lying-in woman of the slums, who is working and scrubbing, while her labor pains are in progress, without a nurse around, left alone in a cold, dingy room!

Premature rupture of the membranes or a precipitated escape of the liquor amnii is frequent among women of the working class, and it is due to their injudicious work. It is their belief that exercise and work, even during the latter part of pregnancy, may bring about an easy delivery. If to the ruptured membranes is added a malposition or a malpresentation of the fetus, and patient is not taken to bed, and further exercises indulged in, a descensus and prolapse of the funis and compression of same may take place, thus causing premature death of the fetus. The infantile mortality in such cases is ranging as high as fifty per cent.

I wish to make a few remarks in regard to puerperal prophylaxis.

Antepartum Prophylaxis.—This implies frequent examinations beginning about the fifth month up to the end of pregnancy, and including measurement of the pelvis, the condition of the heart, lungs, viscera, kidneys, the existence of gonorrhea or lues, and the nerve state. One must pay attention to the breasts to prevent the so-called "milk fever," which is only an invasion of bacteria through the nipple by the way of the galactiferous ducts or way of lymph vessels (Bumm, Escherich). The unhygienic habit of the nursing mother of lubricating the nipple with her own saliva should be prohibited. Frequently have I seen a primapara nurse her own child and that of her neighbor's in order to establish a free flow of milk; and often pups are employed to pump the breasts.

Frequent ablutions of the genitals and sponging of the body are beneficial; full baths, especially in the latter part of pregnancy or during confinement, are not desirable. Edgar believes that there is a distinct risk of infection of the uterus in intrapartum tub bathing. The sedentary habits of some pregnant women bring about a sluggish circulation of blood, defective oxygenation, and predispose to obesity. We therefore meet with so many "fat women." They should be taught the benefit derived from out-of-door exercise.

The question of diet is entirely neglected by the average puerperal woman. There is no doubt that we can reduce the size and flexibility of the fetal head by a fixed dietetic regime to be followed by the mother. The so-called Prochownik's diet has been quite successful in cases of contracted pelvis. The author shows by a series of cases that the maternal diet can so influence the size, weight, and osseous development of the offspring, as to make it possible for the child to be born normally at full term, even though in previous confinements, instrumental means or the induction of labor were necessary. Races of people who subsist chiefly upon vegetables and fruits bear children easily. Prochownik gives his diet during the six weeks preceding labor. It consists mostly of vegetables; starchy and carbohydrate foods are prohibited.

Inactive life or sedentary habits lead to imperfect metamorphosis and induce deficient eliminative action of the body. We should, therefore, not allow the pregnant woman to crowd her system with highly nitrogenous or animal food, which augments urea. For the above reasons, starchy or carbohydrate foods should be prohibited. Uremia may be prevented by dietetic measures. Water should be largely used by the pregnant woman. There is a prevalent idea among the poorer class of women that the pregnant condition requires strengthening and "feeding up" and rich food is used *ad libitum*, thus augmenting the difficulties of her labor.

If an examination reveals the presence of fibroids, either at the lower uterine segment or in the broad ligament, or of ovarian cysts, an operation for removal of the same is indicated and the woman may be permitted to go to term. This procedure is safer than to allow the growths to increase rapidly in size and then interfere with labor, or even cause spontaneous rupture of the uterus. Multiple fibroids complicating pregnancy may be let alone if they are subperitoneal and located in the upper half of the uterus. The submucous or interstitial variety requires surgical interference. Spontaneous rupture of the pregnant uterus due to malignant growths occurs in forty-two to forty-four per cent. in multigravida and six or six and a half per cent. in primigravida. According to Winkel (cited by Edgar), in forty-nine cases of pelvic tumor obstructing labor, the maternal mortality was fifty per cent., while the fetal was ninety per cent. Pinard reports 0.06 per cent. fibroid tumors complicating labors. Litzman found among fifty-six cases of pregnancy with ovarian tumors, only ten normal deliveries. Of three hundred and twenty-one cases of ovarian tumors complicating pregnancy, seventeen per cent. aborted (Renny). If the operation is performed in the early months of gestation, few women abort. According to Renny's observations, twenty-three per cent. of the mothers succumb in the case of ovarian cysts complicating pregnancy, under the expectant treatment. Swan places the mortality at forty per cent. In one hundred and forty-six cases tabulated by Orgler, there was a mortality of 2.7 per cent. in ovariotomies done in pregnant women. Labor and the puerperal period seem to favor torsion of the pedicle, infection, and gangrene of ovarian tumor and peritonitis.

Intrapartum Prophylaxis.—The woman should be prepared as for a surgical operation. This can be accomplished in the poorest families, as it is inexpensive. A wash boiler can be improvised as a sterilizer and the baking stove can be made use of for dry sterilization. All articles coming in contact with the obstetrical field can be thus sterilized. Rubber gloves should be worn. Constipation should be attended to not only during delivery, but many days before it to prevent uterine infection from the *Bacillus coli*. A condition of enterosepsis, fecal toxemia, or stercoral intoxication is one which every practitioner has to fear, and against which he should assiduously guard. There may be an absorption of pyrogenic toxalbumins which could be removed by the emunctories of the system, if the bowels were moving freely. The report of the Lying-in Hospital shows fever due to stercoral intoxication in 3.61 per cent. of the women admitted. The occurrence of acute cholelithiasis or cholecystitis during the puerperium is favored by constipation and the mechanical obstruction of the outflow of the bile. An impacted rectum frequently causes obstruction to the descending head. The same condition is found in patients with

an overdistended bladder; in such cases forceps has been unnecessarily used when catheterization and an enema could have brought about a normal delivery.

If a malposition is detected early, one should be on hand at the beginning of labor and should watch the dilatation of the cervix and preserve the bag of waters as long as possible, and be prepared with anesthesia and assistance. One should not attempt to correct a malposition or do a version single-handed or without anesthesia, as many an infant has been asphyxiated at the last moment during extraction for want of proper help. In internal podalic version gentleness should be used. In the case of a rigid elongated cervix colpeurynters should first be used and one should not hasten at all hazards to get the child out, but keep in mind the possible rupture of the uterus and think of the mother's interests first. Traumatic rupture of uterus due to high forceps, internal podalic version, and accouchement forcé, occurs in 42 to 44 per cent. of cases in multigravidæ and 6 to 6.5 per cent. in primagravidæ. A correct diagnosis at the bedside is imperative, but unfortunately mistakes are frequent. One may watch for hours a nondescending head, only to discover, when introducing the whole hand into the uterus, that one is dealing with an occipitoposterior position which causes the dystocia and which position might have been corrected if recognized earlier. If the true conjugate measures less than three inches, and the only resort is craniotomy, the woman should be taken to a hospital and cesarean section performed, as craniotomy in tenement house surroundings, with a poorly nourished, anemic woman, often means sepsis or the death of the mother. The latest reports of cesarean sections in cases of contracted pelves, in women operated upon before sepsis set in, show good results to mother and child. In a series of five hundred cesarean sections collected in different countries, there was a mortality of less than 6.49 per cent. In the Sloane Maternity Hospital, the mortality following cesarean section was 5.4 per cent. "Blind force" in the use of forceps to non-rotated head or in a contracted pelvis has caused fractures of the pelvic bones, separation of joints, luxations, and has produced traumatism to the infant's head, face, nose, and eyes.

During pregnancy an increased mobility and relaxation of the pelvic articulations occurs physiologically and is due to the increased vascularity of these parts. Rupture of these articulations may therefore ensue, if too much force is used upon the pelvic bones. Spontaneous rupture of the symphysis pubis or of one or both of the sacroiliac articulations may be due to injudicious methods of delivery. In a case of Dr. Goldthwait there was a separation of the symphysis pubis, admitting one finger and also a movement of the bones at the sacroiliac articulations following delivery. Cases of partial subluxation of sacrum and displacement backward are also on record. The pain in such cases is intense and walking is difficult. Forceps traction in the wrong axis of the pelvis has brought about rectovaginal or vesicovaginal fistula or deep sulci and rents into the vaginal walls down to the pelvic bones.

Through the kindness of Prof. H. J. Boldt, I have had the opportunity of examining his patient, upon whom he performed three consecutive operations for injuries sustained during childbirth, following instrumental delivery. I have found a separation of the symphysis pubis of one and a half inches, and a marked luxation of the sacroiliac articulations. The pelvic bones could be pressed together with the hands. The woman was twenty-nine years of age, was a primipara, and had a normal pelvis. Eight days after the instrumental delivery, she presented the following lesions: a complete laceration of the cervix extending up into the lower segment of the uterus, the agglutinated raw surfaces nearly obliterating the uterine canal, a vesicovaginal fistula, a complete laceration of the perineum deep into the bowel, a laceration of the vagina and a prolapsed, retroflexed uterus. The woman was in the hospital for a period of three months. Her injuries to the soft parts are all repaired, but the separation of the pubic bones and the luxation of the sacroiliac articulations are still present.

The desire of some practitioner to "finish up" the case in a hurry, has caused misery to many a woman and child. I have always recognized in such cases the truth of the saying "the more haste, the less speed" and I always regretted my own attempts at expediting delivery. Trendelenburg and the knee-chest postures have been great adjuvants to me in cases of transverse, face, or brow presentations or prolapse of the funis whenever version was necessary, because they favored retention of liquor amnii and gravitation of the descending parts into the deeper pelvis. Walcher's position has been also frequently used with advantage.

The promiscuous handling by some practitioners and nurses of infectious diseases and labor cases should be deprecated. We are deliberately inviting streptococcus and other infections to the puerperal woman by attending cases of infectious nature, while in attendance on obstetric cases.

Anesthesia in the child-bearing woman should engage our attention. Textbooks assert that such women are tolerant to anesthetics, and are even stimulated thereby. To my mind a woman suffering from dystocia and having anesthesia administered after hours of exhaustion, is not prepared for narcosis and should be carefully guarded. At a recent case, my assistant, who is a careful anesthetist, had to discontinue narcosis and use artificial respiration, the woman nearly losing her life after inhaling one dram of chloroform. As she was not a subject of cardiac disease, we may ascribe this sudden asphyxia to her exhausted state.

Post-partum Prophylaxis.—One should see that a nurse is present before and after confinement; many a poor woman is left in charge of an aunt or friendly neighbor to do amateur work and many a physician has been called to face a placenta prævia or postpartum hemorrhage with no assistance in sight. If the perineum is lacerated, it should be repaired at once, if the traumatism is not too severe and the woman is not septic or exhausted. Concealment of laceration for professional reasons is deleterious to the woman and opens an avenue for infection as well as for future rectocele, cystocele, and descensus of the uterus. If one will also reflect that traumatism to the cervix produced during childbirth may be directly responsible for a future carcinoma, one will understand the great importance of prophylaxis of a timely repair. Post-partum high temperature, associated with chills and accelerated pulse, has been frequently ascribed to sapremia due to retained secundines and many unnecessary curettages have been performed. A closer inspection of the lacerated perineum or vulvovaginal space might reveal the presence of a diphtheria-like patch—a local streptococcus infection, which could be successfully treated with bichloride of mercury applications, or pure carbolic

acid swabbing followed by alcohol or iodine, applied locally and followed by dusting with aristol or iodoform, after which the fever and chills regularly subside.

After delivery one should use Credé's method for about an hour off and on; one must not rely upon the action of ergot or the antiquated pad and bandage to induce contraction of the uterus, but use manual compression and not leave the woman in a hurry, as many a post-partum hemorrhage has taken place after the departure of the physician, even in normal confinements, the bleeding being the result of subinvolution of the uterus. The absorption of ergot from the stomach is uncertain as to promptness and degree, and, if an immediate effect is desired, it should be administered hypodermically. Emergencies are frequent and one should be prepared to meet them with hypodermatic stimulation, hypodermoclysis, venous transfusion and rectal saline injections.

The local toilet of the puerperal woman of the tenement house is in the hands of the home-made nurse and consists in swabbing simultaneously the vagina, perineum, and anal orifice, thus infecting the parturient canal. One should order ablutions of antiseptic solutions by the means of a pitcher, which are less dangerous, and should forbid the use of either sponges or the hands. The above-mentioned nurses seldom, if ever, master the use of the catheter. If the postpartum woman happens to have retention of urine for sixteen to twenty-four hours, she is relieved only at the time of the physician's next visit, when the urine is found to be decomposed, turbid, and has an ammoniacal smell, and retention cystitis has appeared. Such cystitides are frequent among poor women and oftentimes tedious to cure.

The infant's bath, contaminated by meconium, nonsterilized diapers, and the hands of such a nurse does more harm than good; clean sponging is less dangerous to the eyes, mouth, skin, and navel wound of the newly-born. I prefer in such poor surroundings the dry treatment of the umbilical wound and no bath. I have frequently seen pustular eruptions developing on the body of the infant after such baths. Especially is this bathing dangerous for children upon whom circumcision has been performed. If the child is fortunate enough to escape infection from the finger nails of the religious quasi-surgeon, known as the "Mohel," it is still at the mercy of the home-made nurse who just as religiously administers this so-called bath by order of the operator, plunging the infant's body, with the fresh wound on the penis and half-healed umbilicus into the water. I have seen the infection carried from the wound of the penis to that of the umbilicus, with the development of an edema of the genitals and an extensive cellulitis of the gluteal region, the child succumbing as the result of unclean surgery. Hemorrhages following circumcision are frequent. As hemostatics "mohels" use vinegar, ice, or fire sponge; as wound dressings they use old washed linen of European importation, absorbent cotton, plain water, vaseline, etc.; more advanced "mohels" use aristol, boracic acid, and solutions of carbolic acid. A thorough scrubbing of the hands and finger nails, and antiseptic preoperative preparations, are out of the question. This kind of surgery is performed every day (some busy "mohels" having four and five operations each day), the outcome being entrusted to benignant nature. The family physician knows all about it, is utterly disgusted with the "mohels," and makes weak attempts to counteract their influence; a task, I admit, not easy of performance, in view of the religious sentiment involved. However, in families whose confidence the physician commands, he should endeavor by the gradual education of the people to interfere, and either to perform this operation himself, or to have absolute supervision over it.

The prophylactic treatment of the mouth and eyes of the infant is known to every practitioner, but not usually followed out. A drop of a 1 per cent. solution of nitrate of silver should be instilled in the eyes of every new born child. While writing the above, I came across the following resolutions of the American Association of Obstetricians and Gynecologists: "A committee on legislative measures has been appointed to prevent ophthalmia neonatorum, and it therefore resolved that definite steps should be taken to secure the enactment of such laws in various States as shall compel the use of proper measures of prophylaxis by the attendant at every confinement—the execution of such State laws to be under jurisdiction of the State Boards of Health."

In the city of Buffalo there exists a law that every midwife shall at once report to a physician the existence of ophthalmia neonatorum, under penalty of a fine for neglect to do so. From tables published by Köstling of Halle, in 17,467 births with no treatment, 9.2 per cent. of the infants developed ophthalmia, while in 24,723 births in which 2 per cent. of nitrate of silver was used, infection developed in only 0.65 per cent. of the infants. In 4,000 births at the Sloane Maternity Hospital in New York, during a period of six years, in which Credé's method was employed, not one case of ophthalmia developed.

Puerperal infection in private practice still ranges high. The report of the Chicago Health Department showed that 7.3 per cent. of all women dying in 1895, between twenty and fifty years of age succumbed to puerperal sepsis. When we consider that a very large percentage of labors are conducted by midwives, we may find an explanation of this alarming condition. In one of the most densely populated sections of New York, over 50,000 children were born in a single year, but only 20,000 of these were delivered by physicians.

Williams, in the "Book of Obstetrics," says, "In private practice it is doubtful whether the results are materially better to-day than they were before the introduction of antiseptic methods for the reason that the doctrines of asepsis have not yet permeated the rank and file of medical men, much less of midwives to whose care is committed a very large proportion of obstetrical cases."

So far we have been dealing with cases in which the already existing puerperium has been disturbed or aggravated by a neglect of prophylaxis. Let us now consider conditions in which pathological lesions of other organs become aggravated by the puerperal state. Phthisis pulmonalis is one of them. The appalling maternal and infantile mortality speaks for itself. Dr. W. Freudenthal shows that nearly every woman suffering from tuberculosis of the lungs and slight tuberculous affection of the larynx, invariably dies if impregnated and permitted to go to term, the child surviving the mother but a short time. According to Kuttner, 72 to 73 per cent. of children born from tuberculous mothers die several weeks after their birth. Out of three hundred and twenty-one deliveries of tuberculous women within one year, 67.9 per cent. of the children died and all of the mothers died. I knew a young woman who was suffering from

phthisis pulmonalis who died shortly after giving birth to a child, which lived only one year, having developed all the symptoms of tuberculosis—enlarged glands, peritonitis, and curvature of the spine. The father also became infected and died of tuberculosis. Pregnancy in such women should be interrupted—the earlier, the better.

Heart lesions and their secondary manifestations are also affected by pregnancy. Cases VII and VIII are types of this nature. Premature delivery or abortion frequently occurs in consequence of changes in the placenta due to heart lesions, or such children may develop ulcerative endocarditis and die. Charpentier reports 220 cases of heart lesions, of which only 128 women were delivered at term.

Diseases of the nervous system are also aggravated by pregnancy. Statistics show that from 14 to 15 per cent. of women in asylums suffer from a psychosis which developed during pregnancy, puerperium, or lactation. Psychoses during pregnancy developed in 2 to 3 per cent. of the cases. According to Jones (cited by Huggins) insanity occurred in 20.62 per cent. during pregnancy; 32.43 per cent. were associated with lactation. During the year 1900, 132,652 cases of child-birth showed a ratio of one case of puerperal insanity admitted into asylums for every 100 accouchements. I knew a young lady who was subject to slight attacks of dementia following a fright, which, however, was amenable to treatment, but which was aggravated by her marriage. She was seized with convulsions during the first attempt at coition, and became so violent during her pregnancy that its interruption was advised by some of our best neurologists. This woman has been in a sanitarium ever since. The space of this paper does not permit me to cite other conditions in which the puerperium produces a baneful influence on the mind and nervous system. In view of the above cited dangerous condition of the puerperal mother and her offspring, the medical profession is justified in resorting to premature delivery in such cases.

Résumé.—In this paper I have endeavored to give my personal observations of the lying-in woman of the tenement house districts, during a period of more than twenty years of obstetrical practice there. These are real pictures of conditions which exist in our great metropolis. The slipshod methods of midwives, "mohels," nurses, and some physicians should be condemned if we desire to be of real assistance to the puerperal woman and worthy of the purposes of our profession. In the prize essay on "Infantile Mortality During Childbirth," Dr. A. Brothers wrote the following: "There can be no question but that pelvimetry has been too much neglected with us; forceps and version have frequently been resorted to with resulting death to the child and often to the mother, where a little care in examination in the beginning might easily have shown that they were not indicated. Many a child and often a mother too could have been saved by careful pelvimetry with the resulting decision to elect cesarean section long before futile efforts at delivery had so jeopardized the life of both mother and child as to make the operation a hundredfold more hazardous. The elective cesarean section is the only operation in the future in cases of excessive contraction, and symphyseotomy for lesser degree. Perforation and craniotomy of a living child will have little place in the practice of the best obstetricians and in the textbooks in the near future." This was written more than ten years ago and the same neglect of prophylaxis exists to-day. Symphyseotomy, with its large percentage of infantile (18.5 per cent.) and maternal mortality (14.4 per cent.), and premature delivery in the thirty-sixth week, showing an infantile mortality of 55 per cent., are not to be commended; we must regard as the operation of election cesarean section. In the Medical Record (November 16, 1907) is described a "New operation for the permanent enlargement of a contracted pelvis," devised by Leon Maire, by which the pelvic bones are separated from 3 to 4 centimeters and even more permanently, thus permitting the subsequent labors to take a normal course. Let us hope that this operation will prove successful and become a boon to the long-waiting and suffering puerperal woman. But at the present time meddlesome midwifery in tenement houses, with blind fanaticism still clings to antiquated methods, and is just as religiously supported by the ignorant suffering woman who fears light and innovation. Every lying-in woman should be provided with a trained nurse during her puerperium and at least during the four days following. Our municipalities in conjunction with rich benefactors should extend this vital help to the poor woman who prefers her home to the hospital. Let the practitioner who comes in contact with the lying-in woman of the tenements impress upon her mind the necessity of antepartum prophylaxis, and the possible dangers that may follow its neglect. Long enough has the general practitioner practised the "*laissez faire*" methods in obstetrics, long enough have we listened to remarks about the "poor," "unclean," "nonintelligent," "multiparous" "woman of the slums," in contrast with her clean, aseptic, rich, well-bred, manicured sister of the beau monde. The improvement in the condition and prophylaxis of the latter lies in her education and enlightenment, and this duty, toward the poor, the family physician must and should perform. "Light, more light," is what is necessary in the houses of such women.

To those who are inclined to disregard these precautions, and who believe these pictures are painted in too vivid colors, I would refer to the gynecological clinics and hospitals of our large metropolis. Their records will show an enormous contingent of patients—a vast amount of gynecological material gathered almost exclusively from the slums of the city—women crippled for life as the result of traumatism inflicted during childbirth, the results of neglect of puerperal prophylaxis at the bedside of the lying-in woman.

Here, as elsewhere, "meddlesome midwifery" may mean "good gynecology."

1885 Madison Avenue.

AIR-BORNE INFECTIONS, THEIR MODE OF ENTRANCE: PREVENTIVE, ABORTIVE, AND AMELIORATIVE TREATMENT.

By W. SOHIER BRYANT, A.M., M.D.,

NEW YORK.

Most infectious diseases have in our day been shown to depend upon a bacterial cause. In many of the diseases without a determined origin a bacterial infection must be inferred because of the similarity of the natural history of these diseases to those which have been proven to have a bacterial etiology. The evidence accumulated for many years, proving that air-borne infections are the most important, is now at our disposal. While the

infections conveyed in fluids or solids are less numerous and have fewer victims, the diseases carried by the air are very many and the list is constantly growing. Tuberculosis, scarlet fever, measles, pertussis, chicken pox, variola, influenza, pneumonia of various kinds, diphtheria, epidemic cerebrospinal meningitis, acute poliomyelitis, acute articular rheumatism, pyogenic bacterial infections, arteriosclerosis, acute nephritis, typhoid fever, etc., are now known to be air-borne infectious diseases.

How do these air-borne infections enter the body? Do they enter by the skin? Probably never without a solution of continuity. It is a noteworthy fact that the skin symptoms of the air-borne infections are always secondary to the lesions at the seat of infection.

Do these air-borne infections enter *via* the alimentary tract? On the contrary, except in a few well-known exceptions, such as typhoid fever, and occasionally tuberculosis, they never enter through this tract. Infection from swallowing bacteria is rare, except for purely intestinal diseases. Even tuberculosis of an intestinal or gastric origin is seldom met with.

The lung symptoms of the diseases under consideration are always secondary to previous local infection in other parts. We have no evidence to the contrary and we may say that the infections we are considering never enter through the lower air tract or lungs without a solution of continuity.

Where, then, do these infections gain entrance to the body? Probably at the spot where the first signs of disease are detected, namely, in the nasopharynx. It has been proved beyond shadow of doubt that this is the road of infection in the majority of the diseases we have named. Note the chronicity of the symptoms, primary local infection and later toxemia, and the sequence of local and general bacterial findings. Some of the best understood of the diseases which show these relations clearly are influenza, scarlet fever, epidemic cerebrospinal meningitis, acute articular rheumatism, diphtheria, etc.

It is a well-known fact that many contagious diseases begin with coryza. It is more than probable that all air-borne infections are, at the beginning of their course, local infections of the nasopharynx. So many zymotic diseases are known to enter the body through infection of the nasopharynx that it is probable that the other air-borne infections do the same thing. In spite of their general symptoms, some of these diseases remain throughout their course localized in the nasopharynx, the general symptoms accompanying the infection being due to toxemia alone and not to the presence of bacteria in the distant lesions. Noteworthy among such diseases are rheumatism, influenza, and probably acute poliomyelitis and endocarditis. Unfortunately, in the treatment of these diseases it is customary to consider only the toxemic symptoms and to disregard the focus of local infection.

What part of the nasopharynx is most open to infection? The lymphatic ring, because here the mechanical or anatomical resistance to inroads of animate or inanimate material is weakest. When the opsonic resistance is overcome the door is wide open for the entrance of bacteria into the system at this point.

Which part of the lymphatic ring offers the least resistance to bacterial invasion? The first tonsil or adenoid. Why? Because of its peculiar anatomical and physiological position. This lymphatic ring is composed of four parts: First, the nasal or first tonsil; second and third, the two faucial tonsils, and fourth, the lingual tonsil. The lingual and faucial tonsils are compressed and wiped by muscular actions which squeeze material from the crypts, stimulating the outward flow of lymph, and rubbing off any substances resting on their surface. The first tonsil has none of these mechanical aids to cleanliness and to the prevention of infection, for it lies in an angular recess of the upper air tract which forms a dead space where the forcible expiration of coughing, sneezing, blowing the nose, hawking, snuffing, etc., have the least abrading and cleansing powers. The wafting motion of the ciliated epithelium is thus reduced to a minimum at this point where there are two currents, one setting in towards the nose and the other towards the pharynx. The most important disadvantage of the first tonsil is that it cannot be compressed by muscular action or wiped by another surface. Moreover, the first tonsil, from the ease with which it suffers solution of continuity, appears to have the weakest membrane of any inner or outer surface of the body. The mucosa which covers it is very friable, especially at the pharyngeal bursa or median crypt. The mechanical result of these anatomical peculiarities is that secretions from this region tend to accumulate *in situ* and hence to collect air-borne particles. These secretions form a culture ground for infectious bacteria close to a door which may be thrown open at any time by a trivial constitutional accident.

Physiologically, the function of all the tonsillar tissue is to pour out lymph and eliminate bacteria. This tissue does not absorb or admit bacteria except under unusual circumstances.

Let us now consider the initial lesion in some of the diseases under discussion. In scarlet fever, epidemic cerebrospinal meningitis, influenza, and variola there is an acute coryza with initial symptoms beginning in the first tonsil. In diphtheria there is an acute infection of some part of the lymphoid ring. In acute rheumatism and arteriosclerosis and rheumatic endocarditis there is subacute inflammation of the first tonsil. The road of entrance of infection in these latter diseases is the first tonsil. This may be so in spite of any macroscopic change. There is usually at least a slight congestion. Hypertrophy of the tonsil is not an indication of bacterial invasion, but perhaps is rather an indication of abnormal effort at resistance. Infection through the first tonsil is facilitated by failure of general or opsonic resistance and local resistance. The latter is most important both because of its efficacy under normal conditions and because of the ease with which, under deranged systemic conditions of slightly defective metabolism or nerve reaction, it becomes ineffective. The chief factor in this local, mechanical safeguard to infection is the physiological mucous excretion which covers a normal mucous membrane. Abnormal systemic conditions are very apt to alter the normal mucus to a pathological product mechanically and bactericidally less protective. This same alteration in the excretion may follow local infection and tend to perpetuate it. An intact mucosa covered with normal mucus entangles foreign animate and inanimate particles, holding them in harmless suspension while it readily flows off or is wafted away by ciliary action to a place where its burden of bacteria can do no harm.

How to prevent infection. Have the nasopharynx kept in a resistant state by general hygiene which increases the opsonins, strengthens the mucous membrane, and produces a normal fluid mucous excretion. Locally this end is accomplished by

correction of pathological or anatomical obstructions and irregularities of the upper air-tract and by the local use of stimulating astringents.

How to abort infection which has already begun. If the initial infection is discovered before the disease is well under way, abortive treatment of the zymotic and contagious diseases is possible. The treatment is sterilization of the infected area and application of stimulating astringents to the first tonsil.

How to lessen the virulence of the attack. This can be done by the same procedure we used at an earlier period of the infection to abort the attack. The efficacy of this treatment is notable in acute articular rheumatism and its complications.

Conclusions: Since the first tonsil is the gate of invasion of almost all infectious diseases, and since it serves for a time at least as the seat of a primary, local infection, the diseases can be prevented or brought to a close by care and treatment of the first tonsil.

I wish to acknowledge my debt to Dr. E. D. Spear whose undaunted courage has inspired me for many years to profit by his example and instruction in this field of medicine.

THE PROBLEM WHICH CONFRONTS THE OTOLOGIST IN THE TREATMENT OF CHRONIC CATARRHAL DEAFNESS.

By CAROLUS M. COBB, M.D.,

BOSTON, MASS.

It is the general impression among the laity and even among a part of the medical profession, that patients with chronic catarrhal deafness continuously grow worse without much reference to any treatment to which they may be subjected. Unfortunately there is some ground for this impression, and it is the purpose of this paper to inquire into the reasons why this may be so. The history of these cases is that they grow worse by repeated attacks or relapses. It is not at all a difficult matter to relieve anyone of these attacks, but it has been a more serious problem to prevent a relapse. The child with catarrhal deafness as the result of adenoids has been the one notable exception.

It is a perfectly justifiable conclusion if a patient suffers from repeated relapses of any disease that the original cause has never been reached and removed. Applying this to the ear we find that practically all inflammations of the middle ear originate from infection by way of the Eustachian tube from the nasopharnyx or nose. It follows therefore that to cure one of these cases, *i. e.* to prevent relapses, it is necessary to find and remove the source of infection in the nasopharynx or nose. This has been done with but indifferent success since the time that the disastrous effects of adenoids upon the ears of children were called to the attention of the profession. The reason for the failure of other operations upon the nose and nasopharynx to produce the brilliant results that followed the removal of adenoids was, in my opinion, due to the mistaken idea that the effect of abnormalities about the nose and nasopharynx was one of mechanical interference with the proper ventilation of the Eustachian tube. If we change our point of view and look upon the congestion of the Eustachian tube and middle ear as active and due to infection rather than passive and due to mechanical obstruction, we shall be in a position to render these patients much more assistance.

I came to the conclusion several years ago that the key to the situation was that most common of all causes of nasal catarrh, obstruction to drainage from the ethmoid cells, and I further believed that I had discovered a peculiar formation of the middle turbinals which was an active factor in this obstruction. I published the results of my observations in the *Archives of Otology*, Nos. 2 and 3, Vol. 29, and in the MEDICAL RECORD of September 7, 1901. When I was asked to open the discussion of Dr. Casselberry's paper at the Atlantic City meeting of the American Medical Association in June, 1907, I again called attention to this condition. The following is the report of that discussion, given in the *Journal of the Association*, Vol. XLIX, No. 2: "Dr. Carolus M. Cobb, Boston, said that in a previous paper he had called attention to a peculiar formation of the middle turbinate which was closely associated with progressive deafness. When seen by anterior rhinoscopy the condition presents a well-marked picture. In the first stage the nasal chambers are rather narrow and generally free from signs of disease of the mucous membrane; the nasal chambers as they form the apex of the triangle superiorly are extremely narrow, and the middle turbinate is not at all prominent in front, but does extend downward in its posterior part, often below the inferior turbinate. The prolongation downward of the posterior part of the middle turbinate is often extremely thin on its front edge, but if investigated it will be found that it immediately grows thicker, and if the attempt is made to introduce a probe between it and the septum it will be found that it is very difficult and many times almost impossible. It is generally as closely applied to the outer nasal wall. The membrane does not have the appearance of congestion or inflammation in the first stage of the disease, but that part of the nose is thoroughly blocked by the bony enlargement of the middle turbinate. It forms such a tight wedge that it is often difficult and sometimes impossible to introduce the blades of the ethmoid forceps on either side of it when one attempts to remove a portion of it. Dr. Cobb has often been compelled to use a fine saw, introduced on the most accessible side, to make a small opening for the introduction of the forceps. The stage of the disease which is marked by this enlargement of the middle turbinate is closely associated with the beginning and progressive stage of the middle-ear disease. Before atrophy takes place he believes that it is possible to arrest the deafness by removing a part of the prolongation of the middle turbinate. Whether this disease is a part of the disease which affects the ears or whether the ear disease is caused by the nasal disease Dr. Cobb is unable to say, but from the fact that an operation on the middle turbinate, before it has reached the stage of atrophy, has a decidedly favorable influence on the ear disease he is inclined to believe that the nasal disease may act as a cause of the aural disease."

The question which naturally arises in regard to any new method of treatment is this, does it accomplish more than can be accomplished by the methods in general use? I can only answer this in so far as it relates to my own experience. After a number of years of observation I am fully convinced that I can accomplish more for my patients by this operation than by all other operations on the nose and throat with the exception of the removal of adenoids. During the last few months I have been fortunate in being able to examine many patients upon whom I operated several years ago, and I have been much gratified with the reports which

they have given me. In fully 80 per cent. of the cases the object aimed at has been accomplished, *i. e.* the relapses to which these patients had been constantly subject were prevented, the hearing had improved as a consequence, and what was of vastly more importance, the improvement was permanent without the necessity of constant treatment. This result I have never been able to obtain by any other method of treatment, even by constant attention to the ears over a long period, by the usual methods of politznigation and massage.

419 Boylston Street.

NITROGLYCERIN IN THE TREATMENT OF NEURITIS.

By H. BURTON STEVENSON, M.D.,

RIDER, MD.

My conception of a neuritis as mentioned in this paper is a condition of inflammation of the sheath and interstitial substance of a nerve, and an infiltration between and degeneration of the filaments. I take this condition to differ from a neuralgia or functional neurosis.

My attention was first called to the use of nitroglycerin in the treatment of this condition by an article by Dr. William C. Krouss of Buffalo, in which he reports seven cases of sciatica treated with this drug with wonderful results. Having met with the same excellent results as Dr. Krouss in the treatment of sciatica I was induced to try the effects of nitroglycerin in cases of neuritis in other parts of the body, with gratifying results.

I wish to report thirty-two cases of neuritis treated with nitroglycerin. I have arbitrarily classified the cases with reference to their duration into acute, subacute, and chronic. Those of under ten days' standing I have called acute, under three weeks' duration subacute, and those over three weeks' duration I have named chronic. Under the heading acute I have placed twenty-one cases, distributed as follows: Six affecting the sciatic nerve and lumbar plexus. Two of sciatic involvement only, and two involving the lumbar plexus alone. Three cases of brachial plexus involvement, one bilateral and two unilateral. Four cases involved the intercostal nerves. Three were of supraorbital neuritis, and one in which both supraorbital and infraorbital nerves were affected.

I have classified six cases as subacute, situated as follows: One brachial plexus unilateral, one bilateral involvement of the radial nerve, one unilateral sciatic nerve affected, and three involving the nerves of the face.

There are seven cases termed chronic, distributed as follows: Four cases involved the sciatic and lumbar plexus, two the sciatic alone, and one a bilateral involvement of the brachial plexus.

The etiology was more or less clear in the group of cases. Fifteen cases were the result of grippe. One followed an attack of typhoid fever, and five were put down to exposure. Of the subacute cases three were neglected acute cases due to influenza, two were diabetic in origin, and in one case the causative factor was obscure.

Of the seven chronic cases five had passed through the preceding phases of the disease without relief when I saw them. Two were neglected grip sequellæ; gonorrhea was supposed to be the cause of two of this group. I have not included cases of neuritis due to pressure or injury in this group, as the treatment of such conditions is obvious.

Nitroglycerin was administered to all these patients in the following routine manner: Beginning with grain 1-100 every eight hours the interval was reduced one hour in every twenty-four until the full physiological action of the drug was manifest or the patient was taking one grain 1-100 every three hours, at which interval it was continued. The disagreeable flushing and headache were controlled by small doses of sodium bromide. When an idiosyncrasy was marked the interval between the doses was lengthened.

The effect of the treatment was marked in the acute cases within the first forty-eight hours. All of the twenty-one cases were discharged within one week, and some a few days before. The subacute cases responded rather more slowly, but were all cured within two weeks. The two diabetic cases in this group responded to the treatment in a few days, but returned in the course of several weeks after withdrawal of the drug. They, however, responded to the treatment when readministered. A marked diminution of the quantity of urine voided and the amount of sugar was noticed when the drug was used. The results in the chronic cases were not so brilliant. The condition was, however, improved in all. Three patients were discharged in three weeks, two in one month; one was greatly improved in three weeks but disappeared from observation. One became discouraged, while improving slowly, at the end of three weeks, and quit the treatment.

In the treatment of the chronic cases ammonium and potassium iodide was given in progressively increasing doses. It seemed to hasten the action of the nitroglycerin. The actual cautery was also employed over the course of the nerve affected. Appropriate treatment for associated conditions was instituted when indicated.

The physiological action of this drug would seem to indicate its therapeutic effect in this disease. By dilating the arterioles of the sheath and nerve the nutrition would be enhanced and absorption of inflammatory deposits would be hastened.

While I do not claim that nitroglycerin will cure all conditions of neuritis, my results justify the belief that it will cure the vast majority of such conditions, and it should have the preference over other treatments which fail more often.

Legal Responsibility in Cases of Death During Anesthesia.— The *British Medical Journal* of January 4, 1908, contains the following opinion on this point from the *English Law Journal*: "Where patients submit, or are subjected to, operations which require, or are better done, under anesthetics, they, and those whose subscriptions maintain the hospitals, are entitled to some guarantee that the utmost skill and care shall be used, and it is well that an inquiry has been instituted with reference to the very frequent deaths in hospitals under anesthetics, for it is not desirable to have these matters decided by a prosecution of doctors for malpraxis or manslaughter. As regards the apportionment of responsibility between the operator and anesthetist doctors differ, and lawyers have not yet been called upon to decide, if, indeed, the question is one of law rather than one of simple fact. In our opinion it really depends on who controls the operation. The necessity for an operation is usually, but not always, decided on by the operating surgeon. When it takes place the control of the operation must be in the operator's hands, but with a skilled anesthetist the fitness of the patient to take the anesthetic must, as a matter of medical judgment and skill, be largely with the administrator."

PHYSICAL TRAINING IN THE ARMY.

THE condition of the rank and file of an army is a matter of supreme importance. It is of little use that soldiers should be versed in all the practices appertaining to their profession if they are not physically fit. In order to withstand successfully the strain of an arduous campaign, a good constitution and a well-knit frame are of far greater value than great muscular strength. It does not follow that because a man has abnormal chest and muscular development he is therefore best calculated to undergo the stress of long-continued exertion. On the contrary, the big man is now at a discount as a soldier, and the middle-sized or small, wiry man is found to be most suitable for waging warfare under present conditions. This fact was conclusively in evidence during the Russo-Japanese war, when the diminutive Japanese showed that they were more than a match in energy and staying powers for the bulky Russians.

Up to the finish of the recent great war in the Far East the German soldier was regarded as the model by military authorities generally. The methods of physical training in vogue in the German army were somewhat slavishly followed by those in control of the principal European armies. Gymnastic exercises were carried to excess, the aim being to have men who presented a remarkable chest development. Within the past few years, however, radical changes have taken place in the way that soldiers are trained. German methods are no longer looked upon as essential to the making of the ideal fighting man, and the large-framed muscular man of the Sandow type is now eyed askance by the up-to-date commander. It is recognized that, while it is an excellent thing that a man should be physically strong and possessed of iron thews and sinews, these qualities are not all that is required, and if in the acquisition of this muscular development he has been rendered unsound in other organs, his strength will avail him little and his value as a soldier will not be much. Physical training is necessary, but such training must be properly directed so that the material at hand may be put to the best account.

A few weeks ago, a meeting of the British United Services Medical Society was held in London, when this subject was fully discussed. The following propositions were introduced, in regard to the physical training of soldiers, by Dr. M. S. Pembery: (1) The true object of physical training should be the increase in the recruit's strength, agility, and capacity for muscular work. The power of endurance is far more important than a conventional military figure, or the acquirement of acrobatic tricks. (2) The principle of progression, from easy exercises of short duration to more difficult exercises of longer duration, is essential, especially for recruits. (3) Unusual movements or postures produce an amount of fatigue and expenditure of energy disproportionate to the work done. (4) The uniform development of all the muscles of the body is unnecessary and uneconomical. The soldier should specialize according to his work. Marching and digging are exercises in which infantry soldiers require progressive training. (5) A "strictly military position" does not assist greatly in the free and full action of the heart and lungs and the consequent development of the whole body. (6) The position of attention is an abnormal position, which can be defended only as a discipline. (7) In marching the natural movements of the arms and the swing of the body should not be suppressed. (8) So-called "breathing exercises" are based upon an erroneous interpretation of the physiology of respiration. In practice they may produce emphysema and increase the risk of infectious diseases. (9) The natural method to improve the "wind" is progressive running. A good "wind" is something more than a big chest; it is the capacity of the heart and lungs to accommodate themselves to the demands made upon them by muscular exercise. (10) The idea that artificial expansion of the chest gives freedom of action to the organs within is erroneous and pernicious. (11) Exercises which produce prolonged fixation of the chest during muscular work are unsuitable for recruits. (12) Training involves the accommodation of the recruit to an outdoor life. Work in the open air "hardens" a man, diminishes his liability to "colds," consumption, and other infectious diseases, and improves his appetite and nutrition. (13) Games have a more beneficial effect than irksome exercises. (14) Obstacle races, boxing, wrestling, swimming, bayonet fighting, and fencing should be encouraged. (15) Exercises with the horizontal bar, parallel bars, pairs of rings, Indian clubs, and dumb-bells should be discouraged. (16) Span-bending, abdominal and dorsal exercises are not free from danger. (17) The official tests of proficiency should be those which bring out a recruit's capacity to coordinate his muscles, to accommodate himself to the demands of muscular work, and to bear fatiguing exercises without undue distress. (18) Military competitions and display should consist of exercises of military value.

In the American army there has at no time been the attention paid to strictly gymnastic exercises, and to the so-called breathing exercises, which has been devoted to these in the European armies. In many respects the army authorities of Europe, outside Germany, and especially those of Great Britain, are adopting principles of physical training which have been practised in our army for many years past. So far as clothing is concerned, although the wearing of clothes can hardly be termed a branch of physical exercises, except perhaps in the case of some German and Austrian regiments, the British army may be said to have been modeled recently on the lines of the American army. As for the so-called breathing exercises, it was pointed out by a

speaker at the meeting that the rhythm of respiration is regulated by the percentages of carbon dioxide present in the blood, which is kept at a constant level of 5.6 per cent., a level which cannot be altered by any artificial exertion. There can be little doubt that progressive training in rational physical exercises is better calculated to render a man fit for and capable of a soldier's work than arduous and irksome gymnastic exercises. On the whole, then, it may be taken as proven that the German or Swedish gymnastic exercises do not turn out the soldier best fitted for the strain of a long-continued campaign, and that the propositions laid down by Dr. Pembery are in the main correct. As for the endurance tests recently imposed upon the elderly officers of our army, we have shown that they are unnecessary and liable to do more harm than good, except to the younger officers whose promotion will be more rapid when those higher in rank are invalided and retired with dilated hearts.

SLEEPING SICKNESS.

In America we have no direct interest in sleeping sickness, but now that this country has imperial concerns and tropical possessions, all the diseases which afflict the lands of the torrid zone naturally fall under the notice of the medical profession here. There is no known malady which spreads so quickly and causes so great devastation as does sleeping sickness. Immense districts of Africa have been absolutely depopulated by its ravages, and unless effective means be found to stay its course, very large tracts of fertile country will be rendered uninhabitable. The study of sleeping sickness has been carried on by scientists of several European countries for a considerable period, and during the past two or three years much energy has been thrown into the endeavor to discover means to check or abolish it. Perhaps the Liverpool School of Tropical Medicine has been the most energetic in this connection.

That the malady is spread by the *Glossina palpalis* has now been known for some years, and those who have studied the subject appear to have jumped to the conclusion that this fly is the sole agency by which the pestilence is disseminated. From a report, however, sent by members of an expedition dispatched to Rhodesia by the Liverpool School of Tropical Medicine in conjunction with the British Government and the British South Africa Company, this view of the situation is not borne out by the facts of the case. Undoubtedly this particular species is responsible for the transmission of the disease in probably the majority of the instances of sleeping sickness, and it may be said to be the chief agent of its dissemination. But that there are other infecting agencies besides this particular species of fly has been demonstrated by the work in Uganda, where successful transmission experiments were made with *Glossina fusca*. Indeed, the work on cattle trypanosomes and other experiments made during a comparatively recent period go to show that all biting flies, and those of the glossina genus in particular, must be looked upon with grave suspicion. Some observers in the Congo Free State have even accused *Stegomyia fasciata*, but it may be stated with some degree of confidence that the tsetse flies are the only insects which carry sleeping sickness, and that, therefore, the wholesale destruction of these flies would result in the checking or extirpation of the disease.

The etiology of the disease is in an unsatisfactory position, and efforts should be made to determine definitely what flies carry the virus. In the report referred to above, extracts from which were published in the *Lancet* of April 11, 1908, it is stated that the British South Africa Company, through Dr. Spillane, has taken elaborate measures to combat the spread of sleeping sickness. In order to set on foot a thoroughly successful campaign against the disease, it will be necessary that the authorities of all the countries in which it is found should combine. It will be useless for one country to take elaborate measures if the neighboring protectorate does nothing. The fact must be well understood that unless effective steps are taken many valuable portions of Africa will be rendered useless to white men.

The Pathogenesis of Localized Tetanus.

It has been sufficiently well demonstrated that the general convulsions, which form such a striking phenomenon of tetanus, are caused by the action of the toxin upon the central nervous system, for the elements of which the toxin seems to have a special affinity. Often, however, these convulsions are preceded by localized tetanic spasms, which involve the muscles in the neighborhood of the wound, that has served as portal of entry to the infecting organism. To explain this some authors have even questioned the selective action of the tetanus toxin upon the nervous system, claiming that the muscles may be directly affected by the poison. Writing in the *Deutsche medizinische Wochenschrift* of April 16, 1908, Dr. Conrad Pochlheimer opposes this view and claims that these local phenomena are due to processes in the peripheral nerves which are very similar in their nature to the so-called "short-circuiting" of electric wires, the stimuli to the muscles being transmitted directly from the sensory to the motor nerves instead of traveling the longer reflex arc to the central nervous system and back. Normally, such "short-circuiting" is prevented by the insulation property of the medullary sheaths of the nerves, but the tetanic toxin affects the sheath in such a way as to disturb its function in this particular. In support of this theory he cites experiments in which he succeeded in producing localized muscular spasms by the injections of chemical substances which had a solvent action upon the medullary sheaths. This view is of interest, not only because it explains the local spasms of tetanus, but because of its bearing upon the more general question of the etiology of such spasms in other diseases. It may well be supposed that the contractions and spasms accompanying such diseases as joint tuberculosis, cerebrospinal meningitis, etc., may be due to a like action of the toxins destroying the normal insulation existing between the sensory and the motor elements which lie side by side in the mixed peripheral nerves of the body.

The *X*-Ray Treatment of Leukemia.

Both the myelogenous and the lymphatic forms of leukemia have for some time been treated with *x*-rays, but a serious objection to this therapeutic measure has been its liability to cause a derma-

titis due to the prolonged and frequent exposures to the rays. Recently von Jaksch has been able to prevent this dermatitis by interposing a thin silver plate between the body and the rays, which at the same time did not alter the latter's action on the spleen and bone marrow. This objection done away with, the *x*-ray treatment of leukemia seemed more promising. Further experience, however, convinced von Jaksch that the rays have other deleterious effects in leukemia. In the *Wiener klinische Wochenschrift* of April 2, 1908, he cites the history of a case in which the treatment diminished the size of the enlarged lymph nodes and spleen, brought the total number of leucocytes to normal, reduced the pathological ones, and increased the polynuclears. After suspending treatment for two months the blood picture of leukemia returned, and the *x*-ray treatment was again instituted for four months. At the end of this time the blood no longer resembled that of myelogenous leukemia but showed a severe secondary anemia which continued for two months, when the patient died. The symptoms before death resembled those of anemia rather than leukemia, while the post-mortem findings pointed to an old chronic leukemia as well as to anemia. We thus see that while the blood changes found in leukemia were made to disappear, the functions of the spleen and bone marrow were distinctly impaired. It is true that leukemia not treated with the *x*-rays may terminate in a fatal anemia, but in the case cited v. Jaksch himself believed that the anemia was caused by too vigorous treatment. He says that prolonged *x*-ray treatment of leukemia as it is practised to-day may cause a secondary anemia, and though the rays need not necessarily be condemned in this class of cases, experience teaches that extreme caution should be observed in their use.

The Etiology of Myopia.

Although it is generally granted that any occupation requiring the accommodation of eyesight to objects close to the eyes form a very important cause for the development of myopia, yet the ultimate reasons for the injurious effect of such work have not yet been satisfactorily brought forth. Dr. Walter Thorner (*Berliner klinische Wochenschrift*, April 20, 1908) thinks that this effect is not due to the efforts of accommodation nor to the pressure exerted by the external eye muscles upon the eyeball in the converging motions of the eye; according to him the principal rôle is played by the difference in the movement of the eye in looking at distant and at nearby objects. In the former case the movements are smooth and continuous; in the latter, broken, discontinuous, and jerky. By means of a specially constructed ophthalmoscope he has been able to watch the motions of the eye fundus in one eye, while the other was used for sewing, writing, and reading, and the latter occupation proved to be accompanied with the greatest number of such movements, some eighteen to twenty-five thousand of them taking place in one hour. The portions of the sclera posterior to the attachments of the muscles bear the brunt of such movements, both their sudden beginning and equally sudden discontinuance tending to weaken it and increase its longitudinal diameter, thus rendering the eye myopic in character. This ingenious explanation of the etiology of myopia deserves further study from the ophthalmologists; its effect upon the prophylaxis of the troublesome condition, however, is in no way an encouraging one. If the cause of myopia lies in the mere act of reading, repeated too often and continued for too long a time, our usual precautions directed toward the selection of proper type, paper, and the abundance of light must play a very subordinate rôle in the prevention of this condition.

Amylnitrite in Hemoptysis.

Several clinicians have recently recommended amylnitrite in the treatment of hemoptysis due to pulmonary tuberculosis. This led C. Tochi (*Gazzetta degli Ospedali*, No. 11, 1908) to try it in a series of cases. He administered from three to five minims at a dose, in form of inhalation, and found that the earlier the drug was given the smaller the dose necessary to stop the bleeding. He believes that if the drug is administered when the first traces of blood appear in the sputum the hemoptysis can be prevented. When we consider that amylnitrite causes an anemia in the pulmonary circulation while producing a congestion of the general circulation, we can readily understand that it might be of benefit in hemoptysis. Tochi's success confirms the good results obtained by other clinicians with the nitrites in pulmonary hemorrhage.

News of the Week.

The Educational Rôle of the Hospital.—At a meeting of the Hospital Conference of the City of New York held at the Academy of Medicine on April 30, 1908, the following report relating to the proposed extension of clinical teaching in the hospitals of the city was presented by Dr. S. S. Goldwater, Chairman: "The Subcommittee on Medical Organization and Medical Education desires to report that during the year a number of conferences have been held with representatives of the College of Physicians and Surgeons (Columbia University), Cornell University Medical College, and the University and Bellevue Hospital Medical College (New York University), respectively, with a view to the formation of a plan for the extension of cooperation between the hospitals of the City of New York and the university medical colleges engaged in the preparation of candidates for the degree of Doctor of Medicine. The Subcommittee on Medical Organization and Medical Education has proceeded on the theory that a larger participation by the hospitals of the city in the work of medical education is desirable in the interest of the public health; and, furthermore, that an increase in the activities of hospitals along the lines indicated is bound to react favorably upon the hospitals themselves. The committee is not yet prepared to present any definite scheme to the conference for its formal indorsement, but hopes to be able to do so during the coming year. In the meantime, the committee desires to report that the faculties of the three colleges named agree that the time has arrived for such a readjustment of the curriculum of the medical school as will enable medical students in the fourth year, or graduating class, to spend additional time in hospital wards, either as clinical clerks and surgical dressers, or as students participating in the work of section classes. Action has been taken by the faculties of all three colleges to promote this object; and in order to indicate to the members of the conference the direction in which negotiations

are tending, the committee includes in its report the following brief quotations from letters addressed to it by college officials.

From Cornell University Medical College: "The faculty (of Cornell University Medical College) has ordered that the hours from 10 A.M. to 12 M. shall be devoted to extramural teaching for as many students as can be at liberty at that time, and in accordance with this resolution the faculty are ready to offer elective courses to our students under any approved teacher. Students in this college use Bellevue Hospital a great deal, and the material is so abundant that I doubt if many of them would like to go far away; nevertheless I sincerely hope that we may be able to post courses in other institutions."

From the University and Bellevue Hospital Medical College: "The faculty of the University and Bellevue Hospital Medical College has unanimously endorsed the principle of extramural teaching for section classes. We are trying at the present time to arrange a schedule of the lectures so as to permit a certain amount of extramural teaching during the afternoon hours. The faculty is prepared to recognize courses of instruction given in hospitals. These courses of necessity would be parallel in scope, time, and nature of instruction to those given by the college, and would be accepted in lieu of required college work."

From the College of Physicians and Surgeons (Columbia University): "The Committee on Administration of the Medical Faculty are of the opinion that the College of Physicians and Surgeons already possesses a sufficient number of section class courses and that it is not necessary to seek further facilities in this particular. It seems to the committee that the chance for development for the hospitals of New York is along the line of the foundation of medical and surgical clerkships. If the hospitals will agree to furnish our students these facilities it will be an addition to what we already possess. I am sure that the faculty will most highly approve of allowing students to take such courses. Each student will be allowed to take both a medical and a surgical clerkship during the fourth year."

Illinois State Board Examination.—A special meeting of the Illinois State Board of Health was held April 25, at which a formal resolution was presented approving of the proposition to subject all applicants for a State license to a practical examination covering one day. In addition there is to be a written examination, requiring three days for completion. It is thought that this plan will be put in operation in October, the time when the Board will conduct its quarterly examination.

The National Volunteer Emergency Service, instituted in 1900, has recently been reorganized by the election of Dr. James Evelyn Pilcher of Carlisle, Pa., as its Director General, and Dr. F. Elbert Davis of New York as its Adjutant General. Its work will be conducted along military lines, the details being worked out in three separate corps, a first aid corps, a public health corps, and a medical corps—the latter consisting of physicians, with rank from Lieutenant to Colonel, according to length of service, to whom are afforded special opportunities for emergency training.

Health Statistics of Chicago.—The death rate for the week ended May 2 was equivalent to an annual mortality of 12.9 per 1,000, being the lowest record for any week for the last six months, and nearly 32 per cent. lower than that for the corresponding week of 1907. The deaths reported were 536, 87 fewer than for the preceding week, and 208 fewer than for the corresponding week in 1907. All the important diseases except heart disease, cancer, and bronchitis show a lower mortality than for the preceding week, and for the first time in a year no death from typhoid fever was reported. Pneumonia caused 68 deaths; consumption, 67; heart diseases, 54; violence, including suicide, 40; acute intestinal diseases, 32; cancer, 29; nephritis, 28; bronchitis, 22, and nervous diseases, 20. There were 10 deaths reported from diphtheria, 4 from scarlet fever, 3 from influenza, 2 from measles, and 1 death from whooping cough.

Status of the Prescription.—The following declaration was adopted at the April meeting of the New York branch of the American Pharmaceutical Association: (1) The prescription should be a signed and dated order from the physician to the pharmacist to prepare and deliver certain medicines, etc., to the patient. The prescription should be written plainly and distinctly, in ink if possible. It should bear the full name of the prescriber, either printed or written, and should state the name of the patient, and if a child, also the age. A telephoned prescription, that is, a prescription which in case of emergency the physician telephones to the pharmacist, must in all cases be repeated by the pharmacist, so as to avoid misunderstandings, and should be followed, especially in the case of potent drugs, with a written order from the physician. In case the physician intends to prescribe an unusually large dose, the quantity of drug should be underlined and be followed by an exclamation mark. General directions, like "As directed," etc., should be avoided. (2) The pharmacist who dispenses the medicine should invariably retain the original prescription for future reference, and as a record, for a limited period, say five years. This for his own protection, as well as that of the prescriber and the patient. (3) The medicine prescribed should be supplied not more than once on the same prescription, in the following instances: (*a*) If ordered by the prescriber "not to be repeated" or marked "Ne repetatur"; (*b*) if it contains medicinal substances, commonly called narcotic or habit forming drugs; (*c*) if asked for by some person known not to be the original holder. (4) One copy of the prescription may be furnished to the patient, but to no other person. This copy should be marked "copy" or "copia," and should be plainly and distinctly written in ink. In the event of the prescriber not desiring a copy to be given, he should note this on the prescription by writing the words, "Give no copy." It would be desirable to have such notation appear on every prescription. Under no circumstances should a copy of the prescription be given, without consent of the physician, after the patient has recovered.

No Canteens for Soldiers' Homes.—The House of Representatives last week voted to keep the canteen feature out of the Soldiers' Homes; the vote was 167 to 46. Since the privilege of drinking beer at home has been denied the old soldiers, and they have been driven to the dives outside the grounds for the alcohol they will, if not must, have, the number of cases of acute and chronic alcoholism has very markedly increased.

Insufficient Public Hospital Accommodations.

—The local visiting committee of the State Charities Aid Association has sent to the Board of Estimate a statement calling attention to the urgent need of additional provision for the sick, particularly the tuberculous and the infirm. Tuberculous patients are most in need of better accommodation, according to the report. Last winter the Metropolitan Tuberculosis Infirmary housed eight hundred patients, an excess of three hundred over the number that can be cared for properly. Provision has been made for the erection of a wing on the tuberculosis infirmary of the Metropolitan in which ninety advanced cases can be cared for, but this is the only permanent relief in sight. Additional accommodation for the tuberculous will be made at Bellevue Hospital by means of the old Staten Island ferryboat *Southfield*, which will be moved at the foot of East Twenty-sixth street and used as an adjunct to the tuberculosis ward of the hospital. The Brooklyn hospitals need repairs and additions badly, the report says, and the almshouses in Flatbush and Blackwell's Island are disgracefully overcrowded.

Child Labor.—On Saturday of last week the House of Representatives unanimously passed a child labor law for the District of Columbia, of which the following are the main features: No child under fourteen to work in factory or store or anywhere else during public school hours, or before 8 o'clock A.M. or after 7 o'clock P.M. Children between fourteen and sixteen employed in any factory or shop must procure schooling certificates. No child under sixteen to work more than eight hours a day or forty-eight hours a week. No boy under ten or girl under sixteen to sell newspapers or other merchandise, or engage in bootblacking on the streets, and all boys under sixteen are required to obtain a permit and badge to pursue these occupations. The National Conference of Charities and Corrections considered at its recent meeting the need of laws to protect children from the evils of factory work. Those who took part in the discussion spoke earnestly against the employment of children in cotton factories. Dr. A. J. McKelway of Atlanta, Assistant Secretary of the National Child Labor Committee, made an earnest plea for legislation for the protection of children. He hoped the day would come when child labor would not be permitted in any State in the Union. Addresses of similar import were made by Professor W. H. Hand of the University of South Carolina and Miss Jane Addams of Hull House, Chicago.

Enlisting the Young in the Fight Against Tuberculosis.—The Young Folks' League for the Home Treatment of Tuberculosis has been organized and has pledged itself to raise funds for the purpose of establishing and maintaining a depot which will distribute free every day three quarts of milk and six eggs to each tuberculous patient who comes with proper recommendations after his case has been investigated by the hospital visiting nurses. It is planned to aid the tuberculous poor throughout the entire city in this manner by district division and management.

Dr. Albert Jansen of Berlin will be the guest of the Section on Laryngology of the New York Academy of Medicine at a meeting to be held on Saturday evening, May 23, in the Academy building. Dr. Jansen will read a paper on "Frontal Sinus Disease."

The Plague in Venezuela.—A dispatch dated May 10, from Curaçao, says that the latest news from La Guayra was that there were twelve cases of bubonic plague in the hospital there on May 7, and two suspected cases are under observation. Instructions have been issued to the employees on the Panama Canal to kill all the rats and mice that they can reach by traps and poison.

American Surgical Association.—At the annual meeting of the American Surgical Association, held May 4-6 at Richmond, Va., the following officers were elected: *President*, Dr. C. B. G. Nancrede, Ann Arbor, Mich.; *Delegate to the American Congress of Physicians and Surgeons*, Dr. Herbert L. Burwell, Boston, Mass.; *Secretary*, Dr. Robert G. Leconte, Philadelphia; *Treasurer*, Dr. Charles A. Powers, Denver Col.; *Recorder*, Dr. Richard H. Harte, Philadelphia. Philadelphia was decided on as the place of meeting in 1909.

Medical Society of the State of California.—The thirty-eighth annual meeting of this society was held at San Diego during the last week in April. The following officers were elected: *President*, W. W. Becket, Los Angeles; *First Vice-President*, Fred Baker, San Diego; *Second Vice-President*, E. G. McConnell, San Francisco; *Secretary*, Philip M. Jones, San Francisco.

Arizona Medical Association.—At the annual meeting of this association, held recently at Tucson, the following officers were elected: *President*, A. W. Olcott, Tucson; *First Vice-President*, J. W. Foss, Phœnix; *Second Vice-President*, C. E. Yount, Prescott; *Third Vice-President*, A. L. Gustetter, Nogales; *Secretary*, J. W. Flynn, Prescott; *Treasurer*, E. R. Ketcherside, Yuma; *Councilor*, J. W. Bacon, Tombstone. The next meeting will be held at Prescott the third Wednesday and Thursday in May, 1909.

Obituary Notes.—Dr. HOWARD CALHOUN died of tuberculosis at Philadelphia on May 3 at the age of twenty-five years. He was a graduate of Jefferson Medical College, and after serving for a short period as resident physician in the Trenton Hospital became a resident physician in the Philadelphia Hospital, where he served for two years.

Dr. HORACE M. HOLMES of Adams, Mass., died on May 3 at the age of eighty-one years. He was born in Waterville, Vt. After graduating from the Bakersfield Academy he went to Illinois, where he taught school, one of his pupils being John Hay, later Secretary of State. He soon took up the study of medicine, and was graduated from the Berkshire Medical College in 1852. After practising for a short time in Cambridge, Vt., he moved to Adams, where he practised medicine for over half a century. He was president of the Berkshire County Medical Society in 1881 and 1882.

Dr. CHARLES HOMER PERRY of Worcester, Mass., died of pneumonia on May 1 at the age of seventy-three years. He was born in Worcester March 17, 1855, and was graduated from Brown University in 1859. He studied medicine at the University of Pennsylvania, but interrupted his studies to serve as a surgeon of volunteers. At the close of the war he entered the Bellevue Hospital Medical College, where he obtained his degree in 1866. He returned to Worcester and practised there, with a break of two years in West Medway, up to the time of his death. Dr. Perry had been a subscriber to the MEDICAL RECORD from its first issue.

Dr. H. BYRON BAGULEY of Wheeling, W. Va., died on May 1, at the age of fifty-one years. He was born in Wellsville, Ohio, and studied medicine at the Cincinnati College of Medicine. Immediately after graduation he went to Wheeling, where he practised continuously up to the time of his death. He was Surgeon-General of the National Guard of West Virginia.

Dr. Joseph O. Farrington, seventy-eight years old, and a native of this city, died May 4 in the Johns Hopkins University Hospital, Baltimore, whither he had gone for an operation, which was performed two weeks ago. Dr. Farrington had been in continuous practice since 1857, in which year he was graduated from the New York University Medical School. He was elected president of the Harlem Medical Association in 1872.

Dr. Louis Debarth Kuhn died May 7, at his home in Brooklyn, in the seventy-ninth year of his age. He was born in East Berlin, Pa., and was graduated in pharmacy and in medicine from the University of Pennsylvania. He served for many years as surgeon to the expedition which surveyed the boundary line between British Columbia and the United States.

Dr. George Schlereth, formerly of this city, died at New Rochelle on May 6, of pneumonia. He was born in Bavaria in 1844, and was graduated from the University in Bamberg, Germany, and also from the Polytechnic Institute in Munich. He came to the United States in 1873, and was graduated from the College of Physicians and Surgeons. He retired from practice five years ago. Dr. Schlereth was for several years physician at St. Francis's Hospital, and was a member of the County Medical Society. He leaves a widow and a son, both of whom are practising physicians.

LETTERS TO A NEUROLOGIST.

To which are appended brief replies purporting to set forth concisely the nature of the ailments therein described, with remarks on their appropriate treatment.

IV.

New York, December 8, 1907.

Dear Doctor:

With the sincere hope that this communication may merit your consideration, I take the liberty of addressing to you some thoughts on a subject which to me is of vital importance.

Deeply impressed by the striking and beautiful conceptions of "The Autocrat of the Breakfast Table," which I have just finished re-reading, a trend of ideas has been excited in my naturally reflective mind, which leads me to confide in you and submit to your judgment that which I have kept even from those nearest me. "And why," you ask, "do you entrust this to the judgment of a stranger, one whose Ego cannot be expected to be in sympathetic accord with your own, unknown and beneath his notice?"

Well,—during my nineteen years of schooling, I have been under many tutors and instructors, but have as yet found few *real teachers*. The average "college professor" is in my estimation often but a poor excuse for that which he represents. You may imagine my pleasure then to make at ——— the acquaintance of one who showed in the highest degree the faculty of presenting his subject in such a form and manner as to make the maximum impression on a receptive mind.—one who, on my mind at least, has left "scars" of live truths, not medical alone. In fact, you impressed me as a social molecule of unusually high and stable intellectual potential, specialized into its highest form. I, also, feel possessed of a certain potential, but fear for its stability, and whether the radiant energy of yours and mine will vibrate in synchronous harmony, which is my desire, remains to be seen. (In all seriousness, I beg of you to interpret this rightly, for though I would expect the average man to see in this but the vagaries of a fantastic imagination loosing itself in a jargon of technical terms, of you I expect more!).

From past experience I know I can trust you to tell me frankly and candidly the unvarnished truth, and if, through my conceits, I am likely to be "doomed to the pangs of undeceived self-estimate," as Holmes has it, I shall experience a genuine pleasure and relief if I can learn from you that I am really only one of the many ungifted with but a "weak flavor of genius, so detestable in a commonplace person." No, I don't think I overestimate myself, but what I may overestimate is my abilities and natural powers of resistance in coping with an environment such as that of New York, should I attempt to carry out the notion to establish myself here. This, as bearing directly on my future, is something I would like to ask you about.

Of one thing I am aware: that through an innate desire for truth and love for pure science, I have now for years (unfortunately through my exclusion and reserve missing much wholesome and broadening social intercourse) led a laboratory existence with books my sole companions, and these, on account of their limited sphere, have caused a localized development confined principally to what I am pleased to call the "higher science"—which harmonizes the cold logic of the mathematical and physical sciences with the real nature of religion, the passions, and all the actions and reactions of mental energy. As a result, I feel and know there have been engendered in me a number of intellectual germs, which to me and my fellow mortals promise much for the future, but whether this green fruit will ever mature, time and the test, "Qu'est ce qu'il a fait" alone will tell. This much I know,—but what I do not know and what I fear, is that coincidently with this one-sided mental development there has taken place a corresponding degeneration, and that the correlation and controlled physiological function of the elements which form the normal *Homo sapiens* have been permanently disturbed, by perhaps a pathological organic change.

This is what I most desire to know from you before it is too late. I take a calm philosophical view of the matter, and believe that, should such a condition exist or be impending, proper precautions may be taken in time, both for the sake of the individual and the community at large. To what do I refer?—Incipient paretic dementia!

I have implicit confidence in you and expect from you the simple plain facts. My previous visits to you and the "advice" which I had wished from you before, but up to this time not asked, had reference to the above to enable you to make some personal observations. Knowing also the diagnostic value of a letter, I send you this which I think you will find offers ample material.

It is good advice to say "Know thyself," but with the best intentions I find myself as much in the dark as before. It is to satisfy my doubts, to see myself as others see me, that I have made this personal appeal to you.

Should you find (what is my present diagnosis), that I am only one of the cases of aggravated neurasthenia, so common in this country, then there may still be a future for one who in his rambling investigations of chemical and physical phenomena has been able to produce a crystallized form of pure ——— which puzzled a professor of chemistry in ——— University, to preserve perfectly in permanent form not only the beautiful "efflorescenses" of H_2O crystallized in such a variety of fern-like forms on the show-windows of shops when the mercury seeks to hide in its bulb in win-

ter, but also that type of evanescence, the soap-bubble, with all its diffractive phenomena fixed and preserved unchanged—and who signs himself,

Most respectfully,

———.

P. S.—I know how busy you are, and how little I can expect from one whom I have perhaps bothered before; I am not even sure that you consider me worth recognizing as a friend or that I may find in you a friend; however, I expect at least a word, if only to say that you would spare me ten minutes of your valuable time and favor me with a diagnosis. If I do not hear from you at all, I shall feel that I have offended you and earned your contempt. This is my last word to you, though you may hear from me in later years.

DEAR SIR:

Deeply impressed by the striking and concluding words of the 22d verse of the fifth chapter of St. Matthew, I restrain my first impulse and say instead "Come from the deep-domed Empyrean down to the earth and be simple and humble."

If you ask in good faith, are you threatened with, or are you entering upon Paretic Dementia, I say to you most emphatically that you are not. Nor are you "one of the cases of aggravated neurasthenia so common in this country." You are not even an unaggravated case. In fact, you are not a case at all. You are not ill. You need a new perspective glass, not to view your own worth, but to aid you to get an appropriate idea of the relation existing between you and the world. You have seen yourself as if reflected from a convex mirror. I suggest that you will get a far more satisfactory idea of yourself if you devote some years to observing the image that is reflected from the other side of the mirror. If you adopt this suggestion the world will discover you if you have merit. Solomon was an uncommonly wise man, as you have heard. Amongst other things that he said is that wisdom is the principal thing; therefore get wisdom; but with all thy getting, get understanding.

In your profession, as in peace, there is nothing so becomes a man as modest stillness and humility. Even a fool when he holdeth his peace is counted wise.

Yours sincerely,

———, Ill.
Feb. 28, 1906.

DEAR SIR,

I take the liberty to address you, I being a stranger, but perhaps you will forgive, when I tell you my age is 17, years.

I wish to ask you a few questions which I trust you will kindly answer. My name is Everette ———, age 17 yr. Do you think that a boy my age could have seminal losses & not know when they take place? Do you think it a sign of health when the cavity or tube of the Penis looks watery, I have been told so by Dr. here in this city? Do you think it natural to sweat around the genital organs to notice it, Do you think these sweatings are greater in winter weather? That is my case. Do you think it very natural to take cold in the Penis, as in the nose, & lose a little fluid? Do you think that after puberty these sweatings are felt more?

Do you think a man can feel the scrotum growing? I mean a stretching sensation. Do you think these sweatings are caused by a long contracted foreskin this Dr. is my case exactly.

But I can't believe what makes me so nervous, in everything, do you think worry and catarrh in nose causes it. (I have catarh also).

Beging your pardon again

I remain truly yours

EVERETTE ———.

DEAR EVERETTE:

Do you think it makes the slightest difference to any one in the world besides yourself that you have made the discovery that you have a penis? If you do, you are mistaken. My advice to you is to forget it.

You can't believe what makes you so nervous, but I think a flogging would cure you.

Do you think you are the whole thing?

Do you know that you might be quite a happy boy if you made yourself go without a meal every time you thought of yourself and your anatomy?

Do you think you could manage to get on for the next four years without mentioning the word I? Do it. It may be health to thy navel and marrow to thy bones.

Yours very sincerely,

Correspondence.

THE PHILIPPINE ISLANDS MEDICAL ASSOCIATION.

[From Our Special Correspondent.]

IMMUNE SERA FROM CITRATED AND CLOTTED BLOOD—MEDICAL EDUCATION IN THE MALAY STATES—SANITATION OF PROVINCIAL TOWNS—QUARANTINE AGAINST PLAGUE IN CEYLON—PHILIPPINE WATER SUPPLIES—SANITATION IN THE BRITISH ARMY—HEALTH CONDITIONS IN THE PHILIPPINES—PRISON SANITATION—BERIBERI IN MANILA—TREATMENT OF ROENTGEN BURNS—CANCER IN THE TROPICS—APPARENT ABSENCE OF THE LIVER—OBSTETRICS IN THE PHILIPPINES—OFFICERS—RESOLUTIONS REGARDING THE DISPOSAL OF HUMAN EXCRETA.

MANILA, P. I., March 1, 1908.

THE third scientific session of the fifth annual meeting of the Philippine Islands Medical Association was called to order by the President at 10 A. M. The first paper read was by Dr. E. Henry Ruediger, Biological Laboratory, Bureau of Science, and Associate Professor of Pathology and Bacteriology, Philippine Medical School, entitled "A Qualitative and Quantitative Comparison of Immune Sera Obtained from Citrated Blood With That Obtained from Clotted Blood." Repeated tests of horse blood and ox blood, to which ⅛ per cent., ¼ per cent., ½ per cent., and 1 per cent. of potassium citrate was added, showed that ¼ per cent. potassium citrate prevents clotting. In blood containing ⅛ per cent. potassium citrate partial or complete clotting frequently takes place. After centrifugating the corpuscles out of the citrated blood and comparing the neutralizing value of the citrated antidiphtheritic, antitetanic and anticholera serum with that of the serum obtained from clotted blood, no difference was found between clotting within twenty-four hours. From citrated horse blood from 20 per cent. to 25 per cent. more serum is obtained than from clotted blood, while citrated ox blood yields only about 5 per cent. more serum than the clotted blood.

The next number on the program was a brief address with regard to the condition of medical education in the Federated Malay States by Dr. R. D. Keith, Physiologist and Assistant Pathologist, Straits and Federated Malay States Medical School, and delegate from the Straits Settlements. Dr. Keith laid particular stress upon the fact that in educating Malays great care must be taken not to overcrowd their minds with exhaustive data. The best success was to be hoped for whenever a moderate amount only was taught them. He was also of the opinion that the ultimate solution of the sanitary problems in the Orient could be expected only through the aid which could be rendered by properly educated native persons who are thoroughly conversant with the language and customs of the people. At the present time we should not expect as high a standard of medical education among them as obtains

now in the first-class schools of Europe and America. He thought that at least several generations of development would be necessary before an equal amount of scientific attainment could be expected from them.

The next paper on the program was that by Dr. Y. K. Ohno, Biological Laboratory, Bureau of Science, entitled "Aggressin Virulence and Local Immunity."

The next paper, entitled "Sanitary Conditions and Needs in Provincial Towns," was read by Dr. Thomas W. Jackson, Contract Surgeon, United States Army. Dr. Jackson said that the sanitary laws and ordinances in the islands left little to be desired, but that there was a woeful lack of enforcement. He said that in his opinion there had been no progress made in this direction during the last few years in the provinces of the Philippines, and that he felt that on account of the fact that much money was being spent in other educational lines, at least a portion of this sum should be devoted to sanitary purposes. He drew a vivid pen picture of the insanitary conditions that exist in provincial towns, calling attention to the disposal of human excrement, which is practically always accomplished by means of the hog, and the unclean appearance of the streets and back yards, and that some summary measures should be taken with the provincial officials for permitting such conditions of affairs to exist. He said that in Manila, on the other hand, striking changes were everywhere in evidence. Great improvement in highways, buildings, sewers, hospitals, schools, and churches, and better conditions as to the control of epidemic diseases were strikingly notable. He felt that the time had come when force should be used in making it obligatory upon the municipal officials of the provinces to abate the nuisances to which he referred.

In the discussion which followed Dr. Heiser said that after all, in his opinion, sanitary reforms which were not supported by a healthy public sentiment must inevitably fail in the end, and that force in the long run had accomplished few permanent sanitary reforms. The economic condition of the islands was such that only limited sums were available for sanitary purposes, in view of which he thought it was better not to risk encountering the passive resistance and opposition of the people, as would be done by enforcing strictly the minor sanitary ordinances, because the opposition which would undoubtedly be engendered in this way would probably defeat the much larger plans which the Bureau of Health has been steadily carrying out during the past few years. To put the matter briefly, he said he believed that it would be much better to spend $10,000 vaccinating the provinces and thereby probably save 1,000 lives per annum, than to devote this sum to municipal street cleaning and abatement of the small mosquito breeding places and providing for the disposal of garbage, which at the best could only be expected to save, comparatively speaking, but a few lives. He laid particular stress upon the fact that from a sanitary standpoint this is practically virgin territory and that the resources for combatting the different conditions were at best very limited, and that he believed that the efforts should be concentrated upon those measures which would save hundreds, as compared to other methods which would save only dozens. He stated that, of course, it would be most desirable to carry out both plans, but under the present conditions it was only possible to have one or the other, in view of which he thought it was best to choose the plan which would give the greatest results. He thought that the fact that there were 6,000 less deaths from smallpox in some six provinces during the past year than has been the case in any other time in the history of the islands, and that artesian wells had been bored in many of the towns, which had resulted in a reduction in the death rate from 40 per cent. to 20 per cent., and that over one-half of the lepers in the Philippines had been segregated at the Culion Leper Colony, which had already resulted in a reduction in the number of lepers from 4,000 to 3,000, and that, with the exception of the provinces which could be reached from Manila by land, no cholera had occurred in the last few years, and that arrangements are now made to remove the more violent cases of insanity from all the provinces to a properly equipped insane hospital, and that many of the modern provincial market buildings which had been recommended, had actually beeen constructed and were in use, would justify the policy which is being pursued and would indicate that much progress has been made in the provinces.

The next number on the program was a brief address by Sir Allan Perry, the Honorable Principal Civil Medical Officer of Ceylon, and delegate from Ceylon, upon the value of the quarantine restrictions enforced at Colombo, Ceylon, in preventing the introduction of plague into that island. Sir Allan laid special stress upon the fact that they are in daily communication with plague-infected ports of India, which are less than forty-eight hours distant, and when it was considered that more than a million cases of plague had occurred in India last year he was of the opinion that their measures were entirely effective. He also gave considerable credit for this happy result to the Indian medical officers, who examine the personnel of vessels before the ships leave the shores of India, and frequently remove cases of plague in the early stages before the vessel sails. He said that in a number of instances plague-infected vessels arrived at Colombo, but these were promptly quarantined and no spread of the disease had taken place.

In the discussion which followed, Dr. Clark of Hongkong and Dr. Keith of Singapore were of the opinion that the equatorial belt—in other words, places which are located within 15° of the equator—for some reason or other were not likely to be visited by a serious plague outbreak. In support of this theory, Dr. Keith called attention to the fact that Singapore was in the direct line of communication, both from India and Hongkong, and other infected places, and that almost invariably all vessels came alongside the wharves; that no particular precautions were taken to prevent rats from coming ashore, and that it frequently happened that plague was found among the rats at Singapore; that the sanitary conditions among the poorer classes, if anything, were worse in Singapore than in any other of the cities in which plague was present, that the *Pulex cheopis* was abundantly found, and that, in spite of all these apparently favorable conditions, there were never more than fifteen cases of plague per annum in that city.

The next paper, entitled "A Biological Study of the Water Supply of the Philippine Islands, with a Description of a New Pathogenic Organism," was read by Dr. Ralph T. Edwards, Biological Laboratory, Bureau of Science. In brief, Dr. Edwards' paper showed that practically all the natural sources of water supply in the Philippines contained amebæ and that the only water which had been found not to contain them was that taken from artesian wells. He made a number of experiments with different filters, but came to the conclusion that the only safe water to drink was that which had been either distilled or boiled. In specimens taken from a well in Calle Cabildo, Intramuros, Manila, a pathogenic bacillus was detected, which he has named *Bacillus Cabildonis*. It is a single bacillus of a breadth of less than one micron and of an average length of two microns. It stains easily with the standard watery dyes, takes a polar stain with Ziel-Nielsen carbol-fuchsin, decolorizes by Gram's method, has no capsule, vacuoles, or crystals, is actively motile, is a facultative anaerobe, grows well either at room or body temperature, grows well on ordinary media, and on transparent media a greenish fluorescence develops; on nutrient broth it remains alkaline and develops no odor; milk is not coagulated, digested, or acidified; no gases form with saccharose, glucose, glycerin, or lactose; solidified blood serum is not peptonized; growth on potato is abundant; indol is produced in sugar free peptone solution, and the organism is of extreme pathogenicity for small animals.

The next number was a brief address by Lieutenant Ryley, Royal Army Medical Corps, in which he gave a brief outline of the sanitary reforms which have been undertaken in the British army in providing for better sanitary administration. He called particular attention to the importance of examining the water supply, to the success of typhoid inoculations, to the value of proper food inspections, and to the advantage of having medical officers proceed in advance of the troops in order to examine the water supplies.

The next paper read was entitled "Health Conditions in the Philippines," by Dr. W. S. Washburn, Director of Civil Service. In this paper Dr. Washburn took occasion to answer many of the criticisms which have appeared in American medical journals during the past year with regard to his former article on tropical climates, which was read before the third annual meeting of the Philippine Islands Medical Association. He quoted most extensively from army statistics and from the reports of the Bureau of Health, and showed conclusively that the mortality and morbidity among those who carried out only reasonable hygienic rules and regulations were not any higher, and perhaps lower, than for persons who reside in the United States and other temperate climates.

The next paper, entitled "The Prevention of Tropical Abscess by the Early Diagnosis and Treatment of the

Presuppurative Stage of Amebic Hepatitis," by Dr. Leonard Rodgers, Professor of Pathology, Calcutta, was read by title.

The next paper, entitled "Prison Sanitation," was read by Dr. E. C. Shattuck, Medical Inspector, Bureau of Health, and Surgeon, Bilibid Prison Hospital. Dr. Shattuck showed most conclusively by diagrams the results which had been obtained in lowering the mortality and morbidity rate at Bilibid prison by freeing the prisoners of their intestinal parasites. He called attention to the fact that at the time this work was undertaken the death rate in the prison was 60 per 1,000 and that after the prisoners were free from their uncinaria and other intestinal parasites, the death rate fell to less than 20 per 1,000 per annum.

The next paper, entitled "Camp Sanitation as Illustrated at Jamestown, Va., and Pasay," was read by Dr. Percy L. Jones, Captain and Assistant Surgeon, United States Army. Dr. Jones gave a brief outline of the methods which have already been extensively described in the medical journals and the manner in which camp sanitation was carried out at Jamestown, and the success which attended it. He passed around photographs showing the character of the garbage furnace which was used for the purpose of incinerating the camp refuse and also photographs of the screened latrines which were used. Both of these were apparently practical conceptions which might be constructed on the ground without the use of special apparatus.

The next paper, entitled "Beriberi in Manila," was read by Dr. N. Saleeby, Physician-in-Chief, University Hospital. He reported that there were many ambulatory cases of this disease in Manila, and found that it was practically all confined to the poorer classes.

The fourth scientific session of the fifth annual meeting of the Philippine Islands Medical Association began at 3 P. M. The first paper on the program, entitled "Mendelian Heredity and Its Relation to Medicine," was read by Dr. Robert B. Bean, Assistant Professor of Anatomy, Philippine Medical School.

The next paper on the program was a brief address by Dr. J. J. Vassal, Institut Pasteur, Nhatrang, Annam, and delegate from Indo-China. Dr. Vassal stated that at Nhatrang he had the opportunity of studying the therapeutic action of atoxyl in seventeen different cases of malaria. The patients were Annamese and came from among the laborers along the railway. Atoxyl was given hypodermically in 10 per cent. solution in 0.5 gram doses at intervals of three days. The temperature remained above normal for sixteen days. The parasitic action of the drug seemed nil, but the general state of health was improved; the spleen diminished in size in an appreciable manner. After this period half a gram per day was given for four days, and at the end of nine days the disappearance of the organism had not yet been brought about. He was, therefore, of the opinion that atoxyl alone was incapable of curing malarial fever. He next gave atoxyl with quinine and had most excellent success with it.

The next paper was entitled "The Treatment of Inflammation by Roentgen Rays," by Dr. W. J. B. Burke, Professor of Clinical Medicine, University of Santo Tomas. Dr. Burke reported three cases which had been treated with the rays with marked success. In a felon of the finger the pain practically disappeared after the first ten-minute application. He also used the *x*-rays in severe cases of boils with marked success. In no case, however, did it abort the lesion, the advantage being the absence of pain and reduction of the time required for recovery from the affliction.

The next paper, entitled "Importancia de la Amputacion de Pirogoff para la Longitud del Miembro," by Dr. Benito Valdez, Professor of Surgical Pathology, University of Santo Tomas, was briefly abstracted and read in English by the Secretary.

The next paper, entitled "The Prevalence of Cancer in the Philippine Islands," was read by Dr. F. W. Dudley, Surgeon, St. Paul's Hospital, and Associate Professor of Surgery, Philippine Medical School. Dr. Dudley stated that as the Filipino population was gradually coming more and more under medical observation, it was evident that the incidence of cancer was fully as high among them as it was among residents of the United States. He expressed the view that the absence of cancer in the tropics which has been frequenlty dwelt upon heretofore was not real, but was only due to the lack of skilled medical diagnosis, and thus the cases of cancer did not find their way into the vital statistics.

The next paper on the program was a brief address by Dr. H. Fraser, Institute for Medical Research, Kuala Lumpur, and delegate from the Federal Malay States. Dr. Fraser made a few preliminary remarks with regard to the work which is being done at Kuala Lumpur Institute with regard to the etiology of beriberi. He stated that their work was now only about half completed and that he was not prepared to announce any results. He did, however, call attention to the remarkable results which had been obtained by Dr. Fletcher about a year ago, at the Kuala Lumpur Insane Asylum, in following the custom of the Timbals, who boiled their rice before it was husked, and among whom beriberi was practically an unknown disease. Dr. Fletcher practically reduplicated this condition in Kuala Lumpur Asylum. Dr. Fraser is now engaged in making a laboratorial investigation in order to ascertain if possible the underlying cause of this condition.

The next paper on the program, entitled, "Contribuciones á la Cirujia Abdominal," was read by Dr. Gregorio Singian, Associate Professor of Surgery, Philippine Medical School. He cited a case of a young Filipino in whom there was apparent absence of the liver. He stated that an exploratory operation was made for the purpose of locating the organ, and that not less than five of the Filipino physicians who were present explored the abdominal cavity, but were unable to find it.

The next paper on the program, entitled, "Recent Advances in the Science and Art of Surgery," was read by Dr. John R. McDill, Surgeon-in-Chief, St. Paul's Hospital, and Professor of Surgery, Philippine Medical School. Dr. McDill dwelt particularly upon the value of gastroenterostomy for ulceration and cancer of the stomach. He reported three cases which he had successfully operated upon.

The next paper, entitled "Obstetrics in the Philippines," was read by Dr. Fernando Calderon, Professor of Obstetrics, Philippine Medical School. Dr. Calderon gave a brief historical account of the superstitions which existed among the masses with regard to child birth in the islands, and called particular attention to the woeful lack of skilled obstetrical services in the Philippines. He stated that, with the exception of the few cases among the better classes who reside in Manila and in the larger towns in the provinces, practically all births were attended by quacks and charlatans, and that this, no doubt, was one of the most important causes of the high mortality in the Philippines. Many of the practices of the charlatans, he said, consisted in prescribing most horrible concoctions, these in some cases being composed of horse urine and feces and other disgusting ingredients. They frequently examined the hand of a parturient woman, and if a transverse line is found completely crossing it, it is the sign of a difficult birth, and it is necessary at the moment of delivery to cover this line with a handkerchief. In other instances certain cylindrical bricks which were manufactured in the country districts especially for the purpose are heated and applied to the abdomen of the patient in order to expel the wind and cold from the womb, which, in accordance with local superstition, are mortal enemies of parturition. The patient, for instance, is never given chicken broth, because the chicken is a winged animal and flies and, therefore, carries with it much air, which might be transmitted to the patient, thus injuring her.

The above paper closed the scientific session and the business session was then held, at which Dr. Ariston Bautista y Lin was elected *President;* Dr. J. M. Phalen, Captain and Assistant Surgeon, *First Vice-President;* Dr. W. S. Washburn, *Second Vice-President,* and Dr. Paul Clements, *Secretary-Treasurer; Councilor for five years,* Dr. P. E. Garrison, Assistant Surgeon, United States Navy.

After the election of officers a general discussion relative to the methods to be adopted with regard to the attacking of the tuberculosis problem in the Philippine Islands was begun. Dr. Heiser invited attention to the fact that Dr. R. P. Strong, Dr. H. T. Marshall, and himself had been named a committee for the Philippines by the International Congress on Tuberculosis for the purpose of collecting data and to formulate a plan as to the best method of attacking the problem. In view of the conditions which exist in the Philippine Islands, the best results are to be hoped for by first removing the intestinal parasites with which the greater portion of the population are afflicted, and thus increasing the resistance of the individual to infection. In order to put this into definite form the following resolution was adopted:

Whereas, It appears that the treatment of the prisoners for intestinal worms has been an important factor in reducing the death rate at Bilibid Prison; and

Whereas, It would appear, further, that over three-fourths of the population of the Philippine Islands is at the present time infected with animal parasites; and

Whereas, Infection with these parasites can be controlled almost absolutely by properly disposing of human excreta which contains the ova of the parasites; and

Whereas, The proper disposal of human excreta will at the same time remove one of the most dangerous channels for the dissemination of other infectious diseases; therefore be it

Resolved, That the Philippine Islands Medical Association does petition the Government of the Philippine Islands, through the Honorable Dean C. Worcester, Secretary of the Interior, that a commission of five properly qualified members be appointed to decide upon the most practical and efficient means for the proper disposal of human excreta, that can be established in these islands; and be it further

Resolved, That the Government of the Philippine Islands be petitioned to make such appropriation and provide such means for the establishment of a working system for the disposal of human excreta as from the report of this commission may appear practical and expedient.

After the close of the general session the delegates proceeded on Sunday afternoon to visit the Naval Hospital at Cavite, where they were entertained by the Naval Medical Officers. A number of very interesting cases of malaria and intestinal infections were shown. Dr. Balch gave a practical demonstration of a simple method by which the opsonic index could be determined. On Monday afternoon the delegates and members of the association were invited by the medical officers of the army to visit the Army Hospital at Fort William McKinley. Here they were shown over the well-equipped wards and were shown the more interesting cases. Colonel Hoff had an army field hospital set up and gave a practical demonstration of the working of the same, each unit being visited and explained.

OUR LONDON LETTER.

(From Our Special Correspondent.)

CLINICAL EXHIBITS AT SOCIETIES—LYMPHATIC PERMEATION IN DISSEMINATION OF CANCER—MEDICAL INSPECTION OF SCHOOLS—R. C. S. POLL AS TO ADMISSION OF WOMEN—THE LATE PROFESSOR ANNANDALE—DEFENSE OF RESEARCH.

London, April 24, 1908.

We have had an abundant supply of clinical material at the societies lately. The section of the Royal devoted to this department has had a successful meeting. The Medical Society of London has held its clinical meeting and other societies have been supplied with cases and demonstrations. I will select a few here and there which seem interesting from different points of view. Banti's disease, so-called, was shown and at the same time a case of "primary splenomegaly" in an anemic Jewess aged 50 who came from a non-malarious part of Russia. Dr. Weber thought perhaps the condition would become that described as Banti's with leucopenia and hepatic cirrhosis. A case of obscure fracture only demonstrable by *x*-rays was shown in a workman who was supposed to have sprained his ankle in July, 1907. Recovery was slow and incomplete, and in March, 1908, skiagrams were taken revealing that a piece had been broken off the inner side of the head of the astragalus and a fissure fracture made through the scaphoid. The value of *x*-rays was further illustrated by a case of Dr. St. Clair Thomson's, who produced a skiagram demonstrating the absence of the left frontal sinus, and mentioned some other points as to examination of this part by the rays. Mr. Symonds showed a man of 52 who had in 1904 undergone complete extirpation of the larynx with removal of the left thyrohyoid and sternohyoid muscles, all surrounding fascia with lymphatics and left thyroid lobe. The trachea was attached to the skin above the sternum. Primary union took place. Gluck's device of carrying a current of air through a rubber tube from the cannula to the lips enabled the patient to speak well enough to continue his work as a tax collector. He had no difficulty in swallowing. Another man was shown from whom Mr. Symonds eighteen months ago removed the left vocal cord for malignant growth. The case displayed the good voice obtainable when the arytenoid is preserved and the opposite cord unaffected.

Left optic atrophy with right hemiplegia followed an accident to a boy of seven. He was run over by a cab and soon developed left pneumothorax, then aphasia and hemiplegia. These improved but he remained blind in the left eye, that disc having completely atrophied. There is now no trace of the left carotid or its terminal branches which are supposed to be blocked.

Optic atrophy as a rare complication of myxedema was also shown. A waiter of 44 admitted two months ago to St. Bartholomew's Hospital. Both discs in this case were atrophied, the left more than the right. The visual field was slightly contracted on the inner side. He could perceive light with the left eye and could count things with the right. The myxedema disappeared under thyroid treatment and he can walk well and has no tremors of the hands, but the optic atrophy remains unchanged.

Two cases of brawny arm in mammary cancer were shown by Mr. Handley, who had treated them by the subcutaneous insertion of silk threads from the wrist to the soft tissues on the proximal side of the affected axillary glands and lymphatics, according to this view that lymphatic permeation plays a most important part in the dissemination of cancer. Dr. Leaf said he had seen similar cases improved by venesection, though the edema recurred after a time, and he suggested a combination of both modes of treatment, a suggestion supported by Dr. Copeman. Mr. Handley replied to this that it would be better to try each method on a different series of patients in order to be able to compare the effect. He suggested that his procedure might be useful in elephantiasis. Here I leave the exhibition of cases to refer to a discussion on Mr. Handley's views which took place at the Bristol Medical Society, where he gave one address in which he expounded his theory of lymphatic permeation as opposed to the common notion of cancerous emboli and as an explanation of dissemination in accordance with definite laws. Mr. Roger Williams thought the lecturer went further than the known facts justified in formulating a proposal to substitute as a general theory lymphatic permeation for embolism. He would restrict the theory to local dissemination. There were many facts which pointed unquestionably to embolism as a frequent occurrence. Thus it was certain that cancer cells existed and multiplied in the blood—and that, too, in almost every part of the circulatory system. As to intraosseous dissemination it is now accepted that the cancerous disease spreads from the medullary blood-vessels. So in the portal area it spreads from the portal veins. Mammary cancer passes to the lungs by the vascular route, and how can this reach the choroid of the eye except by embolism? Many other metastases seemed inexplicable otherwise. Mr. Carwardine questioned whether obvious enlargement of the supraclavicular glands might not contraindicate operation, as there might be permeation also into the upper abdomen. Another speaker asked for statistics and also how far operations were being carried. Mr. Handley, in reply, recognized no difference between metastasis and local spread. But he freely admitted that sometimes cancerous embolism might occur, but he thought this was not very often, and he denied that it played the chief part in metastasis.

A conference of school teachers has been held during the week. At the Wednesday sitting, Dr. James Kerr, Medical Officer of the County Council (Educational Department), read a paper on "The Medical Inspection and Treatment of School Children," in which he referred to the recent act as loosely worded, and said that statistics of weights and measurements did not constitute medical inspection, nor did a record of children's complaints. Such records would be of no value. About 90 per cent. of the school children had some dental defects, and 10 per cent. had defective vision. Of the last, 30 per cent. needed examination by methods inapplicable at schools. But every child he tested as to its vision, hearing, and physical condition in reference to nutrition and anemia. Cleanliness and freedom from vermin were matters for the nurse. A compromise had usually to be struck between what was practical and what was too costly or so impracticable as to be pedantic. The teacher, he said, must be master of his own school; the doctor was his colleague. Some discussion followed. One member said they would not have the millennium through medical inspection, and they must not forget the responsibility of the parents. Another held that the inspection would bring home to parents that responsibility. A third seemed greatly concerned lest the teacher should lose any authority, and emphasized the point that he must be master in his own school with regard to medical inspection as well as everything else.

Dr. Kerr's paper certainly gave no grounds for misgiving in this matter, and the meeting evidently thought so, from the cordiality with which it accorded him a vote of thanks.

The poll of the College of Surgeons is now being taken by post-card on the question of the admission of women to the diplomas, and will be open until July, so as to give time for replies from the colonies. The Council state on the card that they have decided that it is desirable to admit women to the examinations for the membership, and are advised that they have power to do so, but wish to obtain the opinion of the fellows and members. Their legal advisers further say that no woman admitted to the diplomas would be able to take any part in the government, management, or proceedings of the college. It seems a curious course to ask an opinion with so clear an intimation that the matter was decided, but there are other equally singular facts regarding the poll. As there are other bodies freely admit-

ting women, there is no reason why the college should not compete for their fees for the membership, which is only a license to practice. The Fellows elect the Council which governs the college. If women in any number become members, we may be sure they will submit to the higher examination, and when they are admitted Fellows they will claim a vote for the Council. Perhaps before then they will join in the demand of the members for a voice in their college. You know, the members have for years been agitating for recognition without effect. Perhaps women would teach them a lesson in that respect. The Society of Members has sent out a post-card, asking the recipients to disregard the requirement to reply simply yes or no, and to add to the yes, "with full collegiate rights." This may prove a good electioneering move in the interests of members. At present it has been met by an official communique to the press, stating that the President has been informed that an unauthorized post-card has been circulated, recommending that the official requirement should be disregarded, and hoping that all will return the official card in strict accordance with the direction to reply "simply in the form of yes or no."

A proposal to raise a memorial to the late Professor Annandale is put forth at Edinburgh by the Principal of the University and the President of the College of Surgeons.

Sir R. Douglas Powell has been reelected President of the Royal College of Physicians, London.

Inspector-General James Porter, C.B., M.D., has been appointed Director-General of the Medical Department of the Royal Navy, vice Sir Herbert Ellis, K.C.B., resigned. Dr. Porter was lately in charge of Haslar Hospital, and he saw much service in the South African War.

A Research Defence Fund is being organized, with Lord Cromer as President, and Mr. Stephen Paget as Honorable Secretary.

Progress of Medical Science.

Boston Medical and Surgical Journal, April 30, 1908.

Treatment of Abnormal Rigidity of the Cervix Uteri by Deep Incisions.—N. R. Mason reports two cases in which this procedure was tried with success. The operation consists in section of the portiovaginalis only after complete dilatation of the supravaginal portion. It is indicated when it is imperative to empty the pregnant uterus in the shortest possible time by the vaginal route and the patient has a rigid cervix which is not dilated. The primary indication is a primiparous eclamptic. The necessary condition exists when the presenting part of the fetus is separated from the vagina simply by the thick septum of the infravaginal cervix. The author describes his technique in detail and presents the following conclusions: Where immediate delivery is demanded in the presence of an undilated and rigid cervix, multiple deep incisions from the border of the external os to the uterovaginal junction furnish the most rapid and safest method of emptying the uterus. There is no danger of the incisions tearing in cases under full term, or in cases at full term, where the pelvis is normal and the fetus is of moderate size. There is no risk of hemorrhage when clamps are employed before making the incisions. The chance of septic infection is no greater than after the lacerations occurring at the time of normal delivery. The scars in the cervix and vaginal vault cause no trouble in the course of subsequent pregnancies and labors.

The Plaster-of-Paris Bar or Rope.—The preparation of the bar or rope is thus described by R. Soutter. A very wet plaster-of-Paris bandage is rapidly unwound back and forth to the desired length. No attempt is made to rub it or to apply it to the partially applied dressing. When the roll is entirely unwound it is held at one end by one hand, while the other is grasped around it and slid down to the other end, moulding it into a bar. It is then slapped into place and rubbed three or four times. This method of reinforcement is more rapid than the time it takes to describe it. By means of the "plaster rope" the bandage may be made very light. Sometimes it is not necessary to have lightness, but large windows are needed as in cases of suppuration, and yet position is sometimes most important in the class of cases. The plaster is put on in the usual way but not finished. Then a lump of sheet wadding is applied at the point where the "bar" is to be laid. The plaster is then completed. When the window is cut, the wadding roll is removed and the bar forms an arch which is solid as stone, permitting large windows with good margins around the wound and plenty of room for extensive dressings. In case very large windows are needed, two or three wire bridges previously bent are necessary to support the gap.

New York Medical Journal, May 2, 1908.

Psychic Pnenomena of Intestinal Toxemia and their Treatment.—J. C. De Vries presents an elaborate history of one case and summaries of several others. The symptoms which such patients present may suggest tuberculosis, and even cancer. Many cases are characterized by intense depression and dread, often a suicidal tendency. Peristalsis may be perfect and the bowel movements normal, yet the mental symptoms persist. Often the trouble begins with a nervous anemia. In this condition food should be varied and given at frequent intervals. Bitter tonics should precede meals. In the later stages after emaciation has resulted and the condition is chronic, residence at a health resort for several weeks is necessary. Depression of spirits is very marked. The high frequency current, and occasional forced feeding and hydrotherapy consisting of a salt rub, a needle bath, Charcot douche, an electrothermal bath, with an occasional massage, usually effects a cure in these cases. In certain cases nervous dyspepsia is the prominent feature. If the condition is accompanied by neurasthenia, typical tender spots are found. If we are uncertain in our diagnosis, treatment is best begun with the rest cure. Cold baths, shower baths, and vibration are serviceable. Ichthyol in divided doses for an indefinite period or its albuminate (ichthalbin) in combination with the various valerianates is undoubtedly one of the best remedies in relieving the neuralgic type of intestinal derangement.

Abstraction of Calcium Salts from the Mother's Blood by the Fetus.—To this cause J. G. Drennan attributes much of the dental disease of the mother. The fetus requires calcium salts for the development of its own osseous tissues and leaves an insufficient supply for the maternal organism. The maternal teeth are one of the first tissues to suffer, probably partly on account of their position, where other deleterious factors are at work—fermentation and putrefaction of particles of food, the presence of secretions which contain germs, and the acid vomit from the stomach coming in contact with them. At the present time the food of the average woman is not so rich in calcium salts as formerly, for much of our prepared vegetable food, especially celeals, is adulterated, or at best, so refined as to have removed from it that which is most necessary to the human organism. During pregnancy and lactation the mother's food should be richer in calcium salts than at any other time, because she is then to supply such salts to two organisms—herself and her fetus or infant, the latter being greedy for such material. The fruit diet fad makes soft bones for both mother and child. It may lead to osteomalacia in the former. Milk and eggs should be freely used and the salts may be given in such preparations as the syrup of calcium lactophosphate and its similars.

Angulation of the Sigmoid.—T. B. Spence reports one case, his patient being a man of 39 years whose symptoms of two years' duration began with pain in his left side over the course of the descending colon. The pain was sometimes intense, at other times it was a dull ache. At the beginning of the trouble his bowels became constipated and continued so; his feces were either scybalous or fluid, never normal in character, and the pain was more severe when the constipation was most marked. There was a loss of weight of twenty pounds during the first year, and very little after that. One year before the author saw the patient, the latter had an operation for suspected cancer but nothing was found and no relief was obtained. The author's incision included the scar of the former operation and many adhesions were found in the left side of the abdomen. A kinking of the sigmoid was found and the loop formed thereby was held firmly by adhesions, and, even after the adhesions were torn loose, the sigmoid immediately fell back into its faulty position when it was dropped into the abdomen. Because of the difficulty in overcoming the angulation, and because of the possibility of further trouble from the numerous dense adhesions along the course of the descending colon, it was deemed wise to cut out the colon by a short circuit between the small intestine and the sigmoid. An anastomosis was accordingly done, connecting the lower limb of the sigmoid to the ileum at a point about twelve inches from the ileocecal junction. Two rows of sutures were inserted, the inner one being a through-and-through stitch. The hernia was repaired by imbricating the layers of the abdominal wall. On the eighth day after operation the patient vomited a small amount of blood and on the ninth day a much larger quantity. On the tenth day a small enema brought away a large amount of black fecal matter. The loss of blood from the stomach and bowel affected the patient markedly, but he soon reacted and was able to sit up on the nineteenth day. There has not been any of the old pain since

the operation, and at the end of four months there is a complete return of health and strength.

Journal of the American Medical Association, May 2, 1908.

The Value of Hospital Interneship.—The scientific and practical value of a hospital interneship is the subject of this article by the late Dr. Nicholas Senn. First showing how medicine, of all the learned professions, is the one that requires the most careful preparation for practice, it is pointed out that it may be assumed in advance that the hospital interne is one who has been a student and has fully utilized the college opportunities. Medical college of instruction alone is insufficient, and the hospital service of the interne, with its laboratory advantages, opportunities for observing postmortems, the daily observation of the methods of the members of the attending staff, and the exclusively medical atmosphere in which he lives, make a far better preparation for his life work than could be otherwise obtained. The responsibilities he has to assume, at least in part, help to develop character; he is no longer a mere hearer and onlooker, as in the medical school. The association with his colleagues and the acquaintances made with physicians are also a great help when the time comes for him to decide on his future course of life. But the greatest value of all is in the practical training received. A year and a half in a large well-equipped hospital, and under the tuition and supervision of a competent staff, is more than equivalent to ten years of active practice.

Spinal Segments and Visceral Disease.—S. D. Ludlum reviews the literature of the relations of the spinal cord and sympathetic system to localized disease of the internal organs and the anatomical facts on which these relations depend. He concludes from the data of human and comparative anatomy and physiology that in each segment of the cord we may have a viscerosensory ending, a visceromotor center, connecting collaterals to each other and brainward; connected with this same segment are sympathetic fibers and sensory fibers from the skin. We can locate these segments by changes in sensation (Head) or by cutting roots (Sherrington). Each segment may be affected by altered conditions in the viscerosensory tract, and by applying heat or cold or other stimuli to the area of the skin whose nerve-endings are in a segment whence arise visceromotor, vasomotor, or other activities, we can reflexly affect the organ supplied by these tracts. The spinal region including these segments corresponds to distribution in the cord of the cells of the columns of Clarke and the intermediolateral tract. Ludlum deduces from all the facts and from personal observations as to the localization of these spinal segments that by therapy, thermal or manual, applied to the areas of skin whose sensory nerves end in the segment of the cord whence also originate vasomotor and visceromotor fibers to the organs, we can produce a change in the functional status of those organs. Accuracy of localization is needed for the best results: an ice bag applied to the spine from the sixth vertebra down will influence diarrhea; if applied above, the heart and lung vessels are also affected and a large part of the benefit is lost. Other illustrations are given showing the effects of stimuli, thermal, electric, etc., on the heart, lungs, etc.

Modern Conceptions of Syphilis.—A. Schalek points out how our ideas about syphilis have been modified since the discovery of the *Spirochæta pallida* as its causal organism. Formerly, gummata were considered innocuous, as being due to toxins only, and appearing after the active virus had exhausted itself. Now we know that they may be still infectious, and doubtless are responsible for some obscure cases. The spirochetes are, however, only exceptionally found in these late lesions, and are not to be expected in broken down gummata on account of the destruction of the tissues. The difficulties of the staining methods and the necessary training of the eye to detect them put this method of diagnosis out of the reach of the majority for the present, but it is only in the doubtful cases that it is absolutely needed. The finding of the spirochete is only possible before mercury has been taken; this drug is fatal to the germ, a fact that Metchnikoff has shown to be of value in the prophylaxis of the disease. An occasional examination for the spirochete is useful in the treatment of constitutional syphilis, but the fact of its constant appearance in primary lesions makes it unnecessary to wait for the eruption to verify the diagnosis, and renders a radical early commonsense method of treatment practicable. Excision of the chancre, followed by cauterization, seems the rational procedure to eliminate the breeding of the disease. This should be followed by energetic mercurial treatment to destroy all germs that have already entered the lymphatics. Excision also prevents autoinfection. The discovery of the germ and its antidote, mercury, puts the treatment of late syphilis on a scientific basis and shows the uselessness of solely relying on the iodides, which are valuable only in promoting absorption and eliminating toxin. It also has an important bearing on the question of the marriage of syphilitics. Since it is not yet possible to obtain pure cultures of the spirochete, one can only speculate as to the possibilities of opsonic treatment and other modern therapeutics. Interesting experiments are, however, reported with serum diagnosis and serum therapeutics, some of the results being rather encouraging. Immunization experiments have also been made with positive results. One important fact shown is that not every case of locomotor ataxia is of syphilitic origin, and our means of deciding as to the specific nature of certain brain tumors are greatly improved. Our ideas on autoinfection and reinfection have also been changed. It is now known that there is a period during the existence of a chancre when multiple autoinoculations occur, and that there is a time limit to the protection conferred by a single attack of syphilis, after which reinfection may occur. Finger's explanation of recurrent syphilitic lesions seems most rational: Immunity begins and develops gradually with the first appearance of the primary lesion. It increases during the secondary stage, but never becomes absolute. After reaching its climax, it again decreases, until a virus which may have remained latent for a time can produce new pathological changes, or infection from outside sources becomes a possibility.

The Treatment of Eclampsia.—J. F. Moran says that while the etiology of eclampsia is not yet definitely known its clinical phenomena and pathology point to a probable intoxication of maternal, fetal, or combined origin. Its frequency could be greatly diminished if a more careful supervision of women in pregnancy were exercised. The mere examination of the urine for albumin during the latter weeks of pregnancy is not sufficient; the total solids excreted, the constitutional symptoms, and the hygienic conditions must all be carefully observed. The occurrence of eclampsia is rarely without warning, and when the symptoms of a pregnancy nephritis increase in spite of prophylactic measures and brain symptoms threaten, it is highly important to terminate the pregnancy, and the quicker the better. In case of sudden onset, with undilated cervix, the operation of vaginal cesarean section may be required for sufficient prompt delivery. The views as to the use of narcotics in eclampsia are changing, and the large doses of morphine recommended by Veit are not advised. In the beginning of the attack, while the mind is intact and the susceptibility of the nervous system is preserved, there is no objection to the use of morphine, as its quieting effect is salutary, but in unconscious and comatose states it is best to withhold narcotics. Chloroform is a cardiac depressant and this, with its bad effect on the hepatic and renal functions, should limit its administration to the time when intervention is required. Chloral hydrate is a valuable remedy, but is not always tolerated; Moran has found it useful in the prodromal stage and also after delivery. He has also found nitroglycerin useful when reduction of arterial tension and diuresis were desired after delivery. As eliminatives, he recommends croton oil and elaterium during the attack, and when the patient is able to swallow, the saturated solution of magnesium sulphate to further eliminate the poison from the bowels. Diuretics have but a slight and inconstant effect. The free use of normal salt solution, three or four pints every few hours, is also recommended as a rational measure. When there is a full quick pulse, cyanosis, and labored respiration, great benefit may be derived from venesection. It is particularly serviceable when the seizures continue after delivery. The result in any given case will depend on the severity of the attack, the judgment and skill of the physician, and the rigid observance of asepsis. Essential to success is a well thought out plan of prompt but not overzealous procedure based on the various phases of the disease, combined with a knowledge of the condition of the cervix and the changes which it must undergo before pregnancy can terminate or be terminated.

Unexpected Aural Effects of Common Drugs.—G. B. McAuliffe reports a case in which iodide of potassium caused deafness and tinnitus. Recovery was imperfect, a fact which he attributes to the formation of an exudate in the fossula ovalis. He thinks it sounds a warning against the reckless use of potassium iodide in aural disease, as any idiosyncrasy of the patient is hard to predetermine. He also reports cases of aural pain relieved by salicylate of sodium, and of aural fibrosis apparently benefited by ergot.

Pneumococcal Brain Abscess.—R. M. Green reports a case of brain abscess from pneumococcic infection and gives brief abstracts of other similar cases found by him in medical literature. The onset of symptoms was grad-

ual. The patient, a woman, aged 35, first felt tingling and numbness, followed later by gradually appearing right motor paralysis, fever, stiffness of neck, partial aphasia, and dullness of intellect. She grew gradually worse and died nine weeks and two days after the first appearance of the symptoms. The autopsy revealed a pneumococcic abscess of the left optic thalmus, with secondary pyocephalus, ependymitis, basal leptomeningitis and bronchopneumonia. The points of special interest noted were the cellular proportions in the meningeal exudate and in the perivascular and general infiltration (predominance of lymphocytes and plasma cells) and the absence of determinable source of entry of the infection. In the abscess cavity, the ventricular lumen and the bronchial exudate, polymorphonuclear leucocytes prevailed. Lanceolate diplococci were found freely in all the affected tissues, showing a generalized infection.

The Lancet, April 25, 1908.

The So-Called Rheumatic Iritis.—Three cases are detailed by C. Higgens who believes that many cases so-called are really of gonorrheal origin, while the patient may never have had arthritic symptoms. The chief distinguishing features are these: it is painful, often severely so, there are swelling of the iris, generally much photophobia, a strong tendency for adhesions to form, though there is no very great amount of exudation, with much ciliary and conjunctival congestion. There are also a decided inclination to contraction of the pupil which strongly resists the action of mydriatics of which there is often a marked intolerance; a tendency to increased tension; a general intractability, rendering treatment most difficult and its results most disappointing; and an unlimited capacity for recurrences continuing through any number of years. As to the mode of origin the author suggests that in probability, in many men who have had gonorrhea severely and frequently, there is left for any number of years in some part of the urinogenital apparatus a very much attenuated virus which gives no trouble locally, but from time to time becomes more active, and though still setting up no local irritation is capable, after absorption, of causing inflammation in synovial membranes or in the iris; in fact, it looks almost as if the iris becomes on occasions an excretory organ and tries to eliminate the poison, receiving considerable damage to itself in the attempt. There must also be a personal element or an idiosyncrasy in those who suffer, because the proportion of persons who have iritis to those who have had gonorrhea is very small indeed. The treatment of this form of iritis is very unsatisfactory. Mydriatics irritate and rise if torsion occurs frequently, so they must be used with caution. Hot sedative applications are serviceable. Cocaine and adrenalin should be avoided. While giving immediate relief, the latter is but temporary and the after-vascular paralysis leaves the patients worse than before. Internally we should flush out the system by purgatives and copious draughts of hot water, give mercury, iodide, quinine, etc. Salicylates are unreliable. Aspirin will relieve pain. Alcohol should be avoided and the integrity of digestion carefully maintained.

The Influenza Bacillus as a Cause of Fatal Endocarditis After Eight Years?—F. J. Smith suggests that the patient may have been an "influenza carrier" and attaches a question mark to his title, showing that he desires the verdict of his readers as to the truth of the proposition he advances. The patient, a man of 45 years, was admitted to hospital in a condition supposed to be a relapse from typhoid fever. He had had influenza eight years previously. His immediate illness was of two months' duration. At about the end of the first half of this period a cardiac murmur was audible. Later the lungs began to be affected and the murmur increased in intensity, later diminishing. The patient died from progressive asthenia. Autopsy showed a verucose endocarditis of the mitral valve with, in the organs, the usual changes due to endocardial infection. Blood cultures taken during life were negative, as they died out before the bacillus found in them could be induced to grow, but its morphological appearance was typical of influenza and its behavior on artificial media left no dout that it was the true influenza bacillus. The author says that we have in this case a positive demonstration that the illness was due to the influenza bacillus, notwithstanding the fact that it was called typhoid fever and did present what are commonly accepted as the principal features of that disease. It began with severe headache and bronchitis and diarrhea, and with these were associated an enlarged spleen and a rash said to be that of typhoid fever. As no bacteriological test (Widal) was made at that time one cannot wonder at a diagnosis of typhoid fever being arrived at.

Chronic Polycythemia.—This condition was first described in 1892 and then ascribed to congenital heart disease. But few cases are on record. An additional case is contributed by E. Cautley who describes his experience with a man of 47 years who was admitted to hospital with the diagnosis of perisplenitis and slight pleurisy with effusion. Examination of the blood showed 7,500,000 red cells and 50,000 white. The latter were nearly all polymorphonuclears. The case was seen at intervals for over a considerable period, in the course of which the red cells rose to 10,000,000 and the white to 59,000. The patient had a very florid face varying to a cyanotic tint. Still later the white cells rose to 75,000. Death finally resulted from cerebral hemorrhage. Autopsy revealed no assignable reason for the great cell increase. The author notes that although any condition of cyanosis induces polycythemia it does not follow that the increase in the number of red cells is due to the cyanosis in cases of the above type. More probably there is an actual increase in the production of red cells, and the cyanosis is consequent on the increasing viscosity of blood and difficulty in its efficient aeration. The considerable increase in the number of white cells, especially in the polymorphs, suggests that we have to deal with an inflammatory affection of the blood-forming organs, possibly the result of some toxin. In many instances the number of white cells is little increased. So far microscopical examination of the various organs has yielded no positive information. Venesection in this patient certainly relieved the symptoms considerably. The omission of milk from the diet and large doses of sodium citrate did not appear to produce any beneficial effect.

British Medical Journal, April 25, 1908.

Cobalt Test for Visual Acuity.—A. J. Hull says that cobalt blue is a substance which possesses the property of excluding all but the blue and red rays when white light passes through it. A person looking through a piece of cobalt blue glass receives only the blue and red rays. Blue rays, being more refrangible than red, focus sooner than red. If the retina is nearer the lens than normal it will receive the focus of the quickly focussing blue rays, but will only receive a haze of the red rays, which will come to a focus behind the retina. If, on the contrary, the retina is a greater distance from the lens than normal, it will receive the focus of the slowly converging red rays, but will only receive a haze of blue rays, the blue rays having come to a focus in front of the retina. The only appliances required for the test are a piece of cobalt blue glass and a disk of white light. The latter is formed by placing a piece of thin parchment in front of a lamp, or using a lamp provided with a disk of ground glass. If the light thus formed be looked at through the cobalt-blue glass by an emmetropic eye a purple disk will be seen. If the eye be hypermetropic the blue rays will focus on the retina, the red rays behind the retina, the red rays forming a ring around the blue. The hypermetropic patient will therefore describe a blue spot surrounded by red. If the eye be myopic the red rays will focus on the retina, and the divergent blue rays will surround the red. The patient will therefore see a red spot surrounded by blue. The various forms of astigmatism may be also recognized by applying this principle. The distribution of the colors seen by the patients suffering from the various errors of refraction may be experimentally produced by the observer placing before his own eye a cobalt glass and adding various spherical and cylindrical lenses, thus making himself artificially ametropic. This method possesses some distinct advantages in the examination of recruits, candidates for various kinds of employment, and the investigation of cases of supposed malingering. It is possible to determine by one simple maneuver—the placing of a cobalt-blue glass before the patient's eye—first, whether the patient is emmetropic or not, and, secondly, whether he is hypermetropic, myopic, or astigmatic. The test is particularly valuable in conjunction with other tests and methods of examination when examining a suspected malingerer. The disadvantage of the test is that the surgeon is entirely dependent for his conclusions upon the statement of the patient. However, the person under examination is unlikely to know that he can simulate emmetropia by saying that he can see a purple disk, but will describe the distribution of colors associated with his error of refraction. The malingerer, on the other hand, will see nothing incriminating in saying that he can see a purple disk.

Certain Infections of the Urinary Tract, with Special Reference to Tubercle, Gonococcus, and Bacillus Coli Communis.—After discussing the histology and physiology of the different anatomical elements in the urinary tract, G. L. Eastes says that when tuberculosis of the urinary organs has passed the miliary stage, tubercle bacilli can almost invariably be detected in the urine by the use of the centrifuge and microscope. A purulent de-

posit showing a visible trace of blood contains plenty of bacilli. When ulceration is going on, if after the centrifuge, no bacilli are found, it is almost certain that the case is not tuberculous. In the great majority of cases previous to the use of instruments, the infection is single and will remain unmixed throughout the course of the disease if manipulation be avoided, and, as a secondary infection is the most undesirable complication, this leads me to enter a strong protest against instrumentation, except for the most cogent reason. Disastrous results follow the introduction of a second organism, and instruments should be the last resource in diagnosis and treatment. This warning is intended to apply to all urinary diseases with as much force as in tuberculosis. Infection from the *Bacillus coli* is commonest of all, and this organism may attack the perirenal tissues, renal pelvis, ureter, bladder, and occasionally the urethra. Infection through the lymphatic route is common. The poison lodges in the ureter and extension is upward rather than downward. The commonest effect is pyuria, and we may have a systemic toxemia, varying from slight headache and fever to profound septic intoxication. In pure gonococcus infections of the urethra which light up with extraordinary virulence at each attempt at topical medication, gonococcus vaccine is again most useful, raising the resistance of the tissues until a point is reached when local applications act like a charm in curing the disease.

Solitary Kidney.—B. J. Ward enumerates the varieties of fused or solitary kidney, and says that during the routine examination of the body of a man of 30 years who died from valvular heart disease, he felt for the right kidney but found that the usual site of the organ on that side was quite empty and no trace of the kidney could be found, either in the pelvis or elsewhere. On dissection it was also apparent that neither the corresponding renal vessel nor ureter had been developed; there was not even a pad of fat or other tissue to represent the missing organ. The adrenal gland was present and in its usual situation, but was supplied with blood by branches of the diaphragmatic arteries only, the usual aortic branches being absent. The left kidney was twice the normal size, and weighed 12 ounces; it was of the usual bean shape with a smooth surface, and it lay in the normal position. A section showed chronic congestion, the result of a gradually failing heart; its vessels were at least twice the normal size, but the pelvis and ureter were normal both in size and shape. The bladder was healthy, but the trigone gave a very curious appearance, the result of the absence of the right ureteric opening, the plica ureterica, and the interureteric bar. The left ureter opened in the usual situation, and its orifice was healthy; but the band of muscle which passes down from the ureter, and which should interlace with its fellow of the opposite side before passing downwards (forming the prominences of mucous membrane known as the plica ureterica and the interureteric bar), in this case ran straight down to the crista gallinaginis of the prostatic urethra, which it appeared to join. The result of this was to give the base of the bladder a curious lopsided appearance which must be quite characteristic and could not be mistaken if seen by the cystoscope. Methods at our command for the detection of single kidneys are cystoscopy, segregation, or separation of the bladder into two halves by a special instrument which enables one to collect the urine from the two kidneys separately, and inspection of the two kidneys.

Prolapse of the Inverted Bladder Through the Urethra.—C. Leedham-Green saw in hospital a little girl with a small swelling between the labia. On examination, a soft red protrusion could be seen between the labia, about the size of a walnut, and covered with mucous membrane. On abducting the thighs, it was observed that this mucous membrane was thrown into several small longitudinal folds, which, at the neck of the swelling, were continuous with those of the urethra. The small openings of the ureters were distinctly visible on either side of the prolapse, and from them urine was intermittently ejected in a characteristic manner. The whole of the bladder was not affected by the protrusion, although it was large, for a metal sound could be passed in front of it for a short distance into the diminished cavity of the bladder. When the child cried or strained the swelling became tense and larger, and the mucous membrane of the rectum protruded at the anus. Under an anesthetic the prolapse was readily reduced through the dilated urethra, which was large enough to admit the little finger with ease. The protrusion of the bladder seemed to cause little or no pain. The urine was free to escape from the exposed ureters, and the urethra was so lax that the blood supply to the bladder was scarcely interfered with. The delicate mucous membrane, however, had suffered from its exposure, and several small ulcers had developed in consequence. Apart from this special trouble nothing abnormal could be detected in the child. There was apparently no congenital defect of the bladder, urethra nor vagina. She was an unusually healthy, well-developed, breast-fed baby, without a sign of rickets or other constitutional disease. According to the mother the child had never suffered from worms, constipation, or diarrhea, and had never had any difficulty or straining when the bowels were moved or the urine evacuated. Apart from the baby's being somewhat weakly during the first month or two of its life, the mother could not suggest anything that might have predisposed to the condition. Various remedial measures were tried such as strapping the buttocks, stuffing the vagina with gauze, etc., but without avail. Finally, under anesthesia a small amount of liquefied hard paraffin was injected into the periurethral tissue at the neck of the bladder. This measure at once proved successful. The prolapse has not been down since; the cystitis which was present rapidly cleared up, and the child when last seen, some four months after the injection, had perfect control over the bladder. Two illustrations accompany the article, and the bladder appends brief summaries of the histories of 22 similar cases he has found on record.

Berliner klinische Wochenschrift, April 20, 1908.

Etiology of Tuberculosis.—Ravenel in a résumé of the literature upon the infection with tuberculosis by ingestion of food and by contagion comes to the following conclusions: The alimentary canal is a frequent portal of entry of the tubercle bacillus, which is capable of penetrating the healthy mucous membrane of the canal without leaving any traces of such penetration. This occurrence takes place most easily during the digestion of fat. The bacilli reach the blood by the way of the chyle vessels and the thoracic duct; from the blood they find their way into the lungs, being retained there by the filtering property of lung tissue. Such infection by way of the alimentary canal is most frequent in children. The milk of tuberculous cows is often a source of infection, but the present state of our knowledge does not enable us to state the proportion of cases in which this cause is active. Tuberculosis may also be spread by contact, such as takes place in kissing, in performing autopsies, and in cleaning various utensils used by tuberculous patients. Contact infection, however, plays a subordinate rôle in the spread of the disease.

Deutsche medizinische Wochenschrift, April 9, 1908.

The Diagnostic Value of the Ophthalmic Reaction in Typhoid Fever.—Orszag tested the ophthalmic typhoid reaction of Chantemesse in fifteen cases of the disease during the febrile period, in eighteen convalescent patients, and in twenty-one persons suffering from various other febrile and nonfebrile maladies. As the result of these observations he comes to the conclusion that the impossibility of obtaining a typhoid toxin of uniform strength is a serious obstacle in the application of the method, and that on this account the procedure cannot be regarded as practically useful. The appearance of the eye should be considered, not at the expiration of six hours as Chantemesse recommended, but at the end of twenty-four hours, for during the former period a positive reaction may also be obtained in cases that are not typhoid infections. At the end of twenty-four hours most cases of typhoid will be found to exhibit a positive reaction. In febrile cases a negative reaction permits the conclusion that typhoid is very probably not present. Convalescent patients give the reaction in about one-half the cases. In diseases other than typhoid the reaction is usually negative at the end of twenty-four hours, though in some instances positive results were obtained. Attempts to obtain diagnostic indications by means of a cutaneous reaction were unsuccessful.

Bradycardia in Appendicitis of Children.—Bokay considers the subject of bradycardia in appendicitis, especially in children, and describes, with temperature and pulse curves, the cases of ten patients from seven to sixteen years old. He finds that during the period of absorption of the exudate slowing of the pulse lasting from several days to more than two weeks appears almost as a rule. The same thing may be observed after the drainage of an appendicular abscess, and here again the symptom may persist for days. Bradycardia may also follow removal of the appendix during the interval. The pulse rate in children of the age specified may go as low as fifty-two, and in the author's cases it fluctuated between fifty-two and eighty. There does not seem to be any relationship between the bradycardia and the temperature curve. Slow pulse under the above conditions is not an unfavorable sign, and when it appears in cases with periappendicular exudate it may indicate that absorption of the exudate has begun.

Book Reviews.

Diseases of the Nervous System. Edited by Archibald Church, M.D., Professor of Nervous and Mental Diseases, and Medical Jurisprudence, Northwestern University, Medical Department, Chicago, Illinois. An Authorized Translation from "Die Deutsche Klinik," under the General Editorial Supervision of Julius L. Salinger, M.D. With 195 Illustrations in the Text and 5 Colored Plates. New York and London: D. Appleton & Company, 1908.

This is a translation of a German "system," and has the faults and the virtues of works of this kind. The authors are among the best of the German neurologists, Schuster, Schultze, Wernicke, v. Leyden, Redlich, Erb, Remak, Eulenburg, and others, and the work is an exponent of the best teaching of the justly celebrated neurologists of the German-speaking nations of Europe. The different articles are not of equal value, as they never are in composite works of this character, but in general they are all that could be desired. As might be expected of a German work, the best sections in the several articles are those on symptomatology and pathology. The therapy is weak, though it is not strong at best in any neurological treatise, yet the general tone in this important though often hopeless subject is more optimistic than one would expect from German writers. There is sometimes a curious lack of harmony between the two sections of etiology and treatment. In the article on headache, for example, the etiological factor of visual defects is mentioned more than once, but the logical treatment by correction of these defects by glasses is strangely neglected. The translation is excellent, smooth and free from Teutonisms. The typography is good, and the illustrations of a superior order. The work is a valuable addition to the literature of neurology, and one that will be found of service to the general practitioner, as well as the neurologist. It forms one of the volumes of the excellent series, entitled, "Modern Clinical Medicine."

Principles and Practices of Modern Otology. By John F. Barnhill, M.D., Professor of Otology, Rhinology, and Laryngology, Indiana School of Medicine, etc., and Ernest deWolfe Wales, M.D., Associate Professor in the Same Institution. With 305 Original Illustrations, Many in Colors. Philadelphia and London: W. B. Saunders Co., 1907.

Printed on heavy paper (so heavy, in fact, as to make the book a bit burdensome to handle), and with illustrations of unusual clearness, this handsome volume comes to us, a credit to both authors and publishers. The former have had in mind in its preparation five main objects, which are thus stated: To modernize the subject; to correct traditional beliefs; to advocate the earliest possible prophylaxis and treatment; to emphasize the importance of a thorough examination and a definite diagnosis a basis for rational treatment, and thoroughly to illustrate the text. The chapters on the anatomy of the temporal bone, physiology of the organ of hearing, and bacteriology of the ear have been written by Dr. Wales, who has also furnished the matter under the various headings concerning pathology. The rest of the book has been written by Dr. Barnhill. The subdivisions of otological subjects is in the main that usually followed in text-books of this class. It is in reference to accurate definite diagnosis and rational treatment that special commendation may be made. Books of this class are now following each other in such rapid succession that the limits of the columns of a weekly journal permit of only a general consideration, but, with reference to the Barnhill-Wales book, we may say that it is in every way a credit to American Otology, and will, we are sure, become a general favorite with both practitioners and students.

Diseases of the Nose and Throat. By D. Braden Kyle, M.D., Professor of Laryngology and Rhinology, Jefferson Medical College, Philadelphia. Fourth (Enlarged) Edition. With 215 Illustrations, 28 in Colors. Philadelphia and London: W. B. Saunders Co., 1907.

We have already given Dr. Kyle's previous editions favorable notice in these columns. In the present edition, no less than twenty-nine articles on new topics have been added, while a very much larger number have been entirely rewritten. The author is one of the few men in this country who are both clinicians and pathologists, and many of the views advanced on pathology are the result of personal laboratory investigation. Concerning former editions, we said that in "a work of this kind the path traveled must necessarily be a beaten one. Under the head of treatment, the author has been very specific, giving not only the names of remedies, but also their dosage and minute directions for administration. Under such conditions, he is, perforce, dogmatic, and makes some statements which universal experience may not perhaps bear out, but throughout his pages there is the unmistakable stamp of sincere and thorough work and an honest record of personal experience." All this we can confidently repeat with reference to the present edition. If there is one criticism we might make, it is that there is rather too fine a subdivision of varieties of some of the common affections, and while this does not bother the practitioner, who sifts all such matters in the light of his own experience, it is rather apt to bother the student, to whom all such matters are new. In view, however, of the many excellencies of the book, it would be ungracious to lay too much stress on this point. Dr. Kyle's book is eminently safe and sane, and may be commended most warmly to the profession. The chapter on voice and speech is a new feature in the works of this class.

A Short Practice in Aural Surgery. By J. Arnold Jones, M.D., Hon. Assistant Aural Surgeon to the Manchester Eye and Ear Hospital, etc. New York: The John Law Co., 1908.

The author's endeavor "to present a concise account of the principles and practice of modern aural surgery" is evident throughout. The chapter on Clinical Examination discusses this matter at some length, and is worthy of careful consideration. While aural pathology is not taken up as thoroughly as we might expect in a "modern" work, more attention is given to symptoms and treatment. We cannot agree with all the author's ideas of treatment and technique. He freely quotes from the works of Richard Lake. Original plates are few, and the treatise of Politzer furnishes most of those in descriptive anatomy. A vocabulary of German medical terms used in relation to aural surgery, various conversational examples, and a score of formulæ are appended.

Technique Chirurgicale Journalière au Lit du Malade, par le Docteur A. Besson, maitre de conférences à la Faculté libre de Médecine de Lille. Deuxième édition revue et augmentée. Paris: Vigot Frères, 1908.

Over one-third of this little manual is taken up by the consideration of general and local anesthesia, the most prominent place being given to chloroform. The rest of the book treats of the various minor surgical procedures, arranged in alphabetical order, among them the preparation of bandages, catheterization, gynecological examinations, thoracocentesis, vaccination, etc. The directions given are throughout simple and sufficient, and the book should prove of value to the senior student or the interne on the surgical service of a hospital.

A Text-Book of Minor Surgery. By Edward Milton Foote, A.M., M.D., Instructor in Surgery, College of Physicians and Surgeons (Columbia University); Lecturer on Surgery, New York Policlinic Medical School; Visiting Surgeon, New York City Hospital; Visiting Surgeon, St. Joseph's Hospital; Consulting Surgeon, Randall's Island Hospitals and Schools; Formerly Chief in Surgery at the Vanderbilt clinic. Illustrated by 407 Engravings from Original Drawings and Photographs. New York and London: D. Appleton & Company, 1908.

The subject of this volume receives but scant attention in the larger books on surgery and in the average medical curriculum; the result is, as the author correctly states, that "more bad surgery is performed upon the hand than upon the organs of the abdomen." Yet most of the patients in need of minor surgical treatment are found among laboring men and women, who are least able to stand the economic and physical loss caused them by bad treatment. The appearance of a large volume on the subject by a man of Dr. Foote's long and varied experience is, therefore, especially welcome. The author has adopted the topographical method of classifying the various affections, and takes up the head, the neck, the trunk, and the extremities in their turn; in each section, the material is further subdivided into inflammations, tumors, and deformities, while fractures and dislocations are also considered in the affections of the extremities. The symptoms and signs of disease are fully entered into, but the chief stress is laid upon treatment. The directions, moreover, found under the latter heading, are not of a general nature, but are in each case specific instructions of what to do and how to do it. The numerous illustrations serve to drive home the clinical pictures of the various lesions and the results of treatment. In the last section, the dressings, bandages, and the technique of minor surgery are taken up. But one serious omission may be noted, and that is the absence of all mention of Bier's method of treatment by active or passive hypermia; however unsettled its final value, no book on surgery dated with the present year should omit all mention of a principle of treatment that has found such wide adoption in recent years. Dr. Foote's book is a valuable one, and may be safely recommended to the practitioner of medicine or surgery, as well as to the student.

Society Reports.

THE PRACTITIONERS' SOCIETY OF NEW YORK.

216th Regular Meeting, Held April 3, 1908.

The President, Dr. Robert Abbe, in the Chair.

Chronic Myocarditis, with Dilatation and Extra Systole.—Dr. Walter B. James presented a man, 50 years old, for the purpose of demonstrating some interesting cardiac phenomena. The patient first came to the Vanderbilt Clinic with an attack of tachycardia, his pulse averaging 200 per minute. He was cyanotic and short of breath, and stated that he had suffered from similar attacks for many years. An examination of the heart showed evidence of a chronic myocarditis, with considerable dilatation and a slight systolic murmur. The patient was sent to the hospital, and after his admission he developed bradycardia, his pulse falling to 30 per minute. A distinct jugular wave was obtained between the radial pulsations, and on measuring this wave and taking a cardiogram he was able to determine that the wave, which was seen and felt and could be distinctly shown in the radial tracing, was due to ventricular and not to auricular contraction. This phenomenon eliminated heart block, which had been suspected, as it demonstrated that the auriculo-ventricular bundle was intact. The possibility of hemisystole was also suspected, but further investigation and a careful study of the jugular and radial tracings proved that it was a case of extra systole—a not uncommon phenomenon. His pulse was now beating regularly, about 30 times per minute, and each pulsation corresponded with a systole of the entire heart. Almost immediately after each pulsation there was an extra systole, rather feebler than the preceding, and coming as it did so soon after the first, the blood pressure was still so high that this comparatively feeble systole failed to open the aortic valves, and had instead a backward effect, producing a mitral regurgitation, the evidences of which were manifest.

Dr. Francis P. Kinnicutt said that about a year ago he had observed a very similar case in his wards in the Presbyterian Hospital. In that case, as in the one described by Dr. James, there was an alternating tachycardia and bradycardia. In the same minute the pulse might have a rate of from 120 to 180, the beats to the touch being of equal force and regular in rhythm, and an equally regular rate of 40. The change from one to the other was instantaneous. The successive periods of tachycardia and bradycardia were followed by periods of varying duration of a pulse of normal rate and regularity. Unfortunately no cardiograms were obtained. Dr. Kinnicutt believed that the explanation offered by Dr. James was the correct one. The speaker accepted Dr. Mackenzie's definition of extra systole, as limited to the response of auricle or ventricle to a stimulus from some other portion of the heart, but where otherwise the fundamental or sinus rhythm of the heart was maintained.

Cases Treated by Radium.—By Dr. Robert Abbe. The first patient was a schoolboy of fourteen years, who had had extreme hypertrophic granular lids since childhood. Photophobia and mucopurulent discharge were excessive. The case was classified by the ophthalmologists as an intractable one of vernal catarrh, rather than trachoma, which it resembled closely. Eversion of the upper lids showed masses of granulation tissue-like vegetations everywhere on the mucous membrane. For contrast one eye only was treated by radium, the worse one being chosen. One application a month for six months had practically cured the condition.

The second patient, who was still under treatment, was a man fifty years old, who presented himself in November, 1906, with a tumor of the right parotid gland, size of a hen's egg, of six years' duration. Excision of a small piece was made from the growth and the radium tube inserted into the cut. The tumor continuously decreased in size, and now, after the fourth exposure to radium, there was nothing left but a small and apparently inert mass, which had remained unchanged since July, 1907. This growth was reported to be a mixed sarcoma. Photographs and casts of the condition before and after treatment were shown as well as the exhibition of the patient.

The third patient presented was a little girl, who, when she came under Dr. Abbe's observation, had a tumor which occupied the entire parotid region extending beneath the jaw, upward to the zygoma and forward on the cheek. It was regarded as an angiosarcoma. An attempt was made to excise it, but this had to be abandoned on account of its extent, vascularity, and nerve involvement. Application of strong radium in a glass tube was thereupon made. At one time the tube was pushed into the center of the cavernous angioma and left over night. This produced great reaction, high fever, and tenderness in the region of the growth. Since then the mas had become flattened so that it was now scarcely noticeable and apparently nothing remained but the shrunken fibrous remnant of the huge soft tumor.

The next patient was a boy with an extensive tuberculoma of the skin of the hand and foot which had been unsuccessfully treated for seven years by every possible means, including liquid air. After a few applications of radium the lesions disappeared. One year later, soft, pink, cicatricial skin remained, as witnessed.

The next patient was a man with a round-celled sarcoma of two-thirds of the eyelid, who had been unsuccessfully treated by various methods, including six weeks with the *x*-ray. The growth disappeared within eight weeks, after four exposures to radium. The patient had received no further treatment for three years; there were no signs of a recurrence, and it was now impossible to distinguish which eyelid had been involved. This patient was exhibited to the Practitioners' Society in 1905, before treatment.

Dr. Abbe also exhibited casts of two other cases, showing the lesions before and after treatment with radium. One was a case of epithelial cancer behind the ear of six years' standing which had disappeared and remained cured after three exposures. The other was a case of extensive giant cell sarcoma of the jaw in a boy who had been shown at a meeting of the Society about four years ago, before treatment. Under radium treatment the growth, as well as the enlarged glands in the neck, had disappeared, and up to the present time there were no evidences of a recurrence.

On the Occurrence of Epileptiform Attacks in Diabetes Mellitus.—By Dr. Lewis A. Conner. (See page 801.)

Dr. George L. Peabody suggested that possibly arterial changes were present in some of these cases of diabetes in which epileptiform attacks developed. It was well known that arterial sclerosis was exceedingly common in diabetes. It was that factor alone that accounted for diabetic gangrene, for instance.

Dr. Francis P. Kinnicutt said that the epileptiform convulsions and bradycardia of the Stokes-Adams syndrome were so often associated with or dependent upon arteriosclerotic changes that it would be of interest to know whether these vascular lesions were not present in at least some of the cases reported by Dr. Conner. Dr. Kinnicutt asked whether the paraplegia and so-called tabes occurring in the course of diabetes were not commonly regarded as evidence of a peripheral neuritis rather than of spinal cord disease.

Dr. Edward G. Janeway suggested that the evidences of a multiple neuritis sometimes observed in the course of diabetes were perhaps due to the large doses of arsenic that were frequently administered, rather than to the disease itself.

Dr. M. Allen Starr said that Jacksonian attacks had

been observed occurring as a convulsive symptom in uremia; these would naturally be of toxic origin, and the same might possibly occur in the course of diabetes. There were many well-authenticated cases of epilepsy on record in which unilateral attacks occurred during the course of the epilepsy, and many cases of epilepsy began as attacks of the Jacksonian type. Many cases of Jacksonian epilepsy had been reported where no local lesion could be discovered post mortem. The speaker said he could confirm Dr. Kinnicutt's observation that the pseudotabes occurring in the course of diabetes was usually regarded as a peripheral nerve tabes.

Dr. Conner, in closing, said that of the eleven fatal cases reported in his paper, autopsy findings were given in seven, and none of those showed any evidence of cerebral arterial sclerosis, either grossly or histologically. In several of the most severe cases of diabetes, no pancreatic lesion was found. No mention was made in any of the cases of a bradycardia. Most of the patients were comparatively young people. There had been much discussion as to the association of epilepsy and diabetes and the development of glycosuria after epilepsy, but the consensus of opinion seemed to be that to find an appreciable amount of sugar in the urine after an epileptic attack was rare. The pseudotabetic attacks occurring in diabetes were generally regarded of peripheral origin. In addition to convulsive seizures, without apparent lesion, these diabetic patients sometimes present various other nerve symptoms without obvious lesion, such as cord symptoms without any changes in the cord. The convulsions were comparable, as Dr. Starr had said, to those of uremia.

Two Rare Lesions of the Superior Vena Cava, with Specimens.—By Dr. Walter B. James. The first specimen was removed from a man, 41 years of age, who had suffered for a number of years from moderate shortness of breath, and for six months prior to his death had complained of vague pains under the sternum. The sixth of last July he went off on a spree, and when he awoke the following morning the pain under the sternum was more severe and was of somewhat different character. His wife noticed that his face was puffed and dusky. His hands and arms were a little swollen. He went to his work, that of a mason, but was obliged to stop after a few hours on account of the discomfort and pain, and went home. Two weeks after this, the symptoms persisting, he came to the hospital. He was a heavily built man, with general anasarca, and suffering from dyspnea and orthopnea. The face, arms, and shoulders were swollen and cyanosed, relatively somewhat more markedly than was the rest of the body. The heart was moderately enlarged and there was a slight area of dullness extending about an inch to the right of its normal location in the second and third right intercostal spaces. Cardiac impulse was heaving, and there was a slight tracheal tug. Over the above mentioned area of dullness there was a systolic thrill prolonged so that it was almost continuous. Over the base of the heart on both sides of the sternum there was a systolic and diastolic murmur most marked on the right side; and with these, but fairly distinguishable from them, there was a soft, blowing or humming continuous murmur which could be distinctly separated from the above systolic and diastolic murmur. The diagnosis was a small aneurysm of the arch of the aorta which had perforated into the vena cava. The right chest contained a large amount of fluid. This was withdrawn, and reaccumulated repeatedly unusually rapidly, so that he had to be tapped every five or six days with well marked but temporary relief. He lived just three months after the onset of the acute symptoms on July 7, and for the greater part of this time he was in reasonable comfort, part of the time sitting up out of bed. The autopsy revealed an aneurysm the size of a small lemon given off backward from the beginning of the transverse portion of the arch of the aorta closely adherent to the superior vena cava with the lumen of which it communicated with a small oval opening measuring 3 x 4 mm. The edges of the opening were firm and smooth. The chief points of interest in the case were the history of the onset, the length of time the patient lived after the perforation took place, and the presence of all the characteristic signs and symptoms which enabled the diagnosis to be made with positiveness.

The second specimen exhibited by Dr. James was from a patient who was presented to the Practitioners' Society by Dr. William Gilman Thompson, in 1906. For sixteen years he had shown enormous dilatation of the superficial epigastric veins, many of the superficial veins of the thorax communicating with the inferior mammary veins. The blood current in these veins was from below upward. The patient also had pulmonary tuberculosis involving the right upper lobe. The diagnosis at the time he was exhibited was chronic pulmonary tuberculosis with total occlusion of the superior vena cava. The case was described subsequently by Dr. Theodore B. Barringer, Jr.* The patient died under the care of Dr. James, and the heart and lungs were exhibited to the Society showing total occlusion of the superior vena cava at the level of the vena azygos.

Dr. Kinnicutt, who also had had the patient under his care in the Presbyterian Hospital, said that a diagnosis of obstruction to the superior vena cava was made, and as the patient at the time was phthisical the obstructive lesion was believed to be of tuberculous origin

Dr. Janeway said that some cases of obstruction of the superior vena cava got well, perhaps by the establishment of a collateral circulation.

Case of an Orbital Tumor Recurring Fourteen Years after the Removal of the Eyeball.—By Dr. Charles Stedman Bull. The patient was a truckman, aged 68, who first came under Dr. Bull's care on March 16, 1908. The left orbit was partially filled by a black, lobulated, very soft, pultaceous mass, over which the eyelids closed easily. The mass bled freely with the slightest touch, but was entirely painless. The patient gave the following histor: In 1885, twenty-three years ago, he came under the care of Dr. Agnew at the Manhattan Eye and Ear Hospital for a protrusion on the front of the eyeball, which prevented the closure of the eyelids. It proved to be a corneal staphyloma, apparently arising from a neglected ulcerated pannus of the cornea, due to granular lids. The staphyloma was excised in the usual way and the sclera stitched together, the case healing promptly. The eye gave him no further trouble until the autumn of 1894, nine years later, when he noticed a return of the protrusion. He then came to the New York Eye Infirmary under the care of Dr. Noyes. The protruding mass was pigmented and connected with the iris, and after watching the case for some time, Dr. Noyes advised the enucleation of the eyeball, which was done on March 1, 1895. No macroscopic evidence of disease was found in the orbital tissue, and the patient was subsequently fitted with an artificial eye. Half of the globe was mounted and kept in the laboratory museum; the other half was prepared for microscopic examination, and the sections showed it to be an extensive spindle-cell melanosarcoma of the iris, which had extended to the ciliary body and chorioid. The patient wore his artificial eye with comfort until the present winter, when he noticed that he had difficulty in inserting the eye between the lids, and in February, 1908, this became impossible. On March 16, under cocaine, Dr. Bull removed as much of the soft pultaceous mass as was possible. The tissue bled profusely, but a careful examination of the orbit did not reveal any localized tumor. Under the microscope, the specimens removed from the orbit showed an edematous mass of loose connective tissue, filled with immature, poorly-defined cells, together with numerous ordinary round cells, and some newly-formed connective tissue cells. The growth contained considerable pigment; the vessels were small and their walls thin. In view of the history of this case, and

*Medical Record, April 20, 1907.

the very suspicious nature of the sections examined, the pathologist of the infirmary, Dr. George S. Dixon, thought he was warranted in regarding the present growth as a form of melanosarcoma. On April 1 Dr. Bull cleaned out the entire orbit of a rapidly-growing, soft, melanotic tumor, and he was then enabled to determine that the growth had invaded the ethmoid cells and extended from the ethmoid into the superior nasal meatus. The sphenoid was apparently not invaded, but the growth extended into the sphenoidal fissure. The floor of the orbit was sound, and the maxillary antrum was not involved. No attempt was made to remove the periosteum of the orbit or to clean out the adjacent sinuses, as many years' experience had taught the futility of attempting a total or radical removal of a malignant growth which had once invaded the sinuses connecting with the orbit, and that every such attempt at a radical removal hastened the return of the growth and tended to shorten the life of the patient.

Dr. Abbe said that about twelve years ago he saw a case where the entire antrum and nasal fossæ were invaded by a hemorrhagic sarcomatous mass. A radical operation was done, both external carotid arteries being simultaneously ligated and the tumor removed, together with the upper jaw and the nasal bones. The patient was still alive and in perfect health, without recurrence twelve years after the operation.

Dr. Bull, in closing, said he had no doubt that the original growth, dating back to 1885, was a sarcoma of the iris. There were no evidences at present of any metastatic growths elsewhere in the body. It was formerly thought that any tumor involving the eyeball and invading the orbital tissue must be thoroughly eradicated, but experience has shown that it was impossible to clean out a growth after it had once invaded the sinuses adjacent to the orbit, and that any attempt at a radical operation usually shortened the patient's life.

A Case of Acute Ascending Myelitis.—Dr. M. Allen Starr reported this case. The patient was a boy of seventeen who, after competing in a running race with some of his school-fellows, was extremely exhausted. About a week after the race he began to complain of malaise and general fatigue, and had slight incontinence of urine. The next day his legs became weaker, until he could scarcely get about. Within a week he became totally paralyzed from the waist down, and there was incontinence of urine and feces. From day to day the paralysis ascended, gradually involving the arms and shoulders, and when Dr. Starr first saw him the face was slightly affected and the neck was stiff and painful. After remaining in this condition for two or three days, the paralysis subsided from the face and the stiffness of the neck disappeared. At the present time he was in a state of apparent complete paraplegia below the sixth rib, with marked weakness and reaction of degeneration in all the muscles of the arm up to the deltoid. These cases of rapidly ascending myelitis, Dr. Starr said, were extremely rare, and were usually due to an infection. In this case the spinal canal was tapped and the fluid carefully tested on various media, with entirely negative results. No evidences of any infection could be found so far as the spinal fluid was concerned.

Dr. Starr also reported the case of a young woman who, after dancing all night, went out during a severe snow storm, and upon her arrival home she was unable to pass urine. During the night both of her legs became paralyzed and there was incontinence of urine. Her symptoms gradually subsided, and now, at the end of three years, she was perfectly well with the exception of a small anesthetic area in the groin. In her case, the last symptom to disappear was the incontinence of urine.

Dr. Kinnicutt, in discussing Dr. Starr's case of ascending myelitis, said that two or three cases had been reported in which the typhoid bacilli were found in the cord. This raised the possibility that at least some of these cases were of bacterial origin.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON MEDICINE.

Stated Meeting, Held April 21, 1908.

Dr. Herbert S. Carter in the Chair.

The Association of Tuberculosis of the Lungs with Diabetes Mellitus.—Dr. Henry L. Shively read this paper. He said that for two diseases so essentially different in their nature as were pulmonary tuberculosis and diabetes mellitus, there were certain points of analogy between them which were at once curious and striking. Diabetes was to be considered a typical example of a disease of metabolism, of disturbed function due to the action of unknown toxins originating within the body itself, and it was assumed that the pathological basis of true diabetes was a congenital or acquired insufficiency of certain histological structures of the pancreas. Both diseases were usually progressive in their course and were regularly attended by emaciation; in both there was an impairment of the power to utilize carbohydrates; both diseases were very fatal in early life, and were, on the other hand, comparatively well withstood when they appeared after middle age. Both diseases had strong racial affinities. Both were more common in cities than in the country, and in both the hereditary predisposition was of some account in the etiology. In both diseases drug treatment was of relatively little value as compared with the importance of detailed attention to hygiene and diet. The prognosis in both was largely dependent upon the social and financial status of the patient. Both diseases exercised a decided effect upon the psychical attitude and morale of the patient. Finally both tuberculosis and diabetes were often associated in the same person. In most cases the tuberculosis was secondary to the diabetes, but this was not invariably the case. The tuberculous tendency of diabetics was now, however, very generally considered to be due to the hyperglycemia and hyperglycosis of their tissues, for it was well known that the tubercle bacillus had a "sweet tooth," developing most luxuriantly in a culture medium to which sugar had been added. Frequent as was the association of the two diseases, one or the other in its early stages was not infrequently overlooked. Tuberculosis of the lungs in diabetics, especially of the obese type, frequently ran an atypical course. It had frequently been observed that when phthisis developed in a diabetic subject there might be a marked diminution in the quantity of urine and the percentage of sugar would fall, delusive signs of improvement. The diabetes continued unchecked, and was hastened in its progress by the complicating tuberculosis. Diabetics who neglected their diet and thus invited an access of glycosuria were more likely to become tuberculous. The recognition of the coexistence of diabetes and tuberculosis had an important bearing on the prognosis and treatment of the patient. Not infrequently, in examining tuberculous patients, individuals were discovered to be diabetic who had had no instruction as to diet and who had been receiving a syrupy cough mixture and cod liver oil with extract of malt, the latter consisting of more than 50 per cent. maltose, which was immediately converted into grape sugar in the intestine. Some of these patients were found to have developed a marked acidosis. The presence of acetone bodies, which were to be regarded as forerunners of the danger of coma, made it a question of more than theoretical interest whether the administration of large quantities of oils and fats, which was an important part of the dietetic treatment of tuberculosis, might not possibly hasten a fatal termination in diabetic coma. Fortunately, many of the indications for treatment were the same for both diseases. One could not too strongly urge the importance of safeguarding the diabetic from tuberculous infection. Of six cases of associated diabetes and tuberculosis recently under observation at the tuberculous clinic of the Presbyterian Hospital, in all but one the diabetes

preceded the development of the pulmonary disease. In this case the patient was undoubtedly tuberculous at least a year and a half before the appearance of the diabetic symptoms. In four cases the tuberculosis developed eighteen months, twelve months, seven months, and two months respectively after the patients were known to be diabetic. In the remaining case the time could not be ascertained. A valuable and seemingly practical extension of the work of district nurses and the diet kitchen, which had been so helpful in the tuberculosis clinic, would be the instruction in the preparation and supervision of food for the diabetic, which was now very imperfectly attended to in the tenement home.

Dr. Charles M. Cauldwell said that twenty-five years ago the late Dr. Alfred Loomis, knowing that Dr. Cauldwell was handling many cases of consumption, asked him to investigate carefully a few hundred of the cases in order to find out how many had diabetes; this was to give Dr. Loomis an idea as to how they were running clinically in New York. He expected to find a large number of the consumptives, those advanced and far advanced in the disease, with sugar in the urine. Among 506 cases examined, only 16 had genuine diabetes. In 23 there was a small quantity of sugar at times only, and with no other symptom of diabetes. They would not have suspected sugar in the urine, and it was found only because of the systematic examinations made of those cases under their care. Almost all the patients were Irish or German or Americans of Irish parentage. There were a very few English, French, and Swedes among them. The proportion of only 16 cases of associated diabetes among 506 patients known to be tuberculous he believed to be much smaller than really existed to-day if one looked over a a like number of cases in this city. With regard to the use of arsenic in the treatment of these patients, he did not believe sufficient emphasis had been brought to bear on it. He thought that if they could expect anything from the use of drugs, in the majority of the cases, in addition to the proper diet, much could be expected from pushing arsenic; this would cause at least a temporary disappearance of the sugar and produce a marked improvement in the patient's condition. Arsenic must be pushed to its highest point; it should then be held at that point, and later increased if the patient would tolerate it.

Dr. Walter Mendelson said that the concurrence of diabetes with tuberculosis in cases occurring in private practice was not so great as Dr. Shively's statistics would seem to indicate. He said he had seen many cases of diabetes in the course of his practice, and yet he could recall but one patient who subsequently developed tuberculosis. There was no doubt but that the class of patients had a great deal to do with the association of these two diseases.

Dr. Leonard Weber said he had tried to divide cases of diabetes into two series, first, those occurring from infancy to thirty-five years old, and, secondly, those occurring between thirty-five years and seventy or over. Of four cases he recalled three were girls, and one was a boy. One of them developed acute diabetes after an acute attack of scarlet fever; another after the administration of large doses of bromide of potassium; he could not recall what diseases preceded the diabetes in the other two. Of seven cases four or five developed acute tuberculosis, and two of them died after three months; the post mortem in these cases showed a breaking down of the lung tissue. There was certainly a predisposition for diabetics to become infected with the tubercle bacillus, as there was after any acute disease whose character was not only severe but deleterious. He reported the case of a man, thirty years old, who always was perfectly well, but occasionally became intoxicated. One winter he became intoxicated in Brooklyn, returned home standing on the ferry boat, was chilled and, four weeks later developed an acute diabetes. He died within one year from pulmonary tuberculosis. In the second series of cases there were found many which were generally subacute or chronic. Among these cases there was not a single one, so far as he had been able to determine, in which tuberculous deposits in the lungs were even suspected. With regard to acidosis of the blood, and the fact that it might not be the cause of coma in these cases, Dr. Weber said he was decidedly of the opinion that it was the cause. Oxybutyric acid was the great power that destroyed life in acute diabetic coma. He reported the case of a lady, seventy-two years old, who had an attack of coma, not very severe. She had had diabetes for eighteen years. When in this coma he caused the bowels to be freely evacuated, and then gave two or three ounces of bicarbonate of sodium in twenty-four hours, continuing it for three days, and the patient is alive to-day.

Dr. Henry S. Stark said that after a careful study he had come to the conclusion that there was no pathological relationship that could be established between these two diseases; this opinion was based upon clinical observation. He had recently made ocular tuberculin tests in 18 cases of diabetes, and he was surprised to get negative results in 95 per cent. of the cases. Most of the patients were well-established diabetics, with suspicious symptoms, including cough, and it was to be suspected that a tuberculous lesion accompanied the disease. He proved that there was no pathological relationship between diabetes and tuberculosis. In many of the skin manifestations, such as carbuncles, furunculosis, etc., sections were taken and subjected to microscopical examination, and the tubercle bacilli, which might be expected to be present, were never demonstrated. Consequently he came to this conclusion, that there was no pathological relationship between the two diseases. With regard to the sanatorium treatment which the doctor advocated, it was a difficult matter to get diabetics to submit to sanatorium treatment, because, as a rule, they were well people; many confirmed diabetics were never aware of their condition until told by the insurance examiner. He emphasized the fact that diabetics were very liable to tuberculous infection. The real relationship between these two diseases existed only in the fact that the tissues of the diabetic made an excellent pabulum, especially for the growth of the streptococci. With regard to the relationship between diabetic coma and acidosis, he said he had on several occasions denied such a relationship. He was about the first to deny that oxybutyric acid was a cause of the diabetic coma. He believed, however, that if proper facilities were to be had for examining the urine, oxybutyric acid could be demonstrated in the urine in every confirmed diabetic.

Dr. A. Mayer did not believe that the question of age entered materially into this relationship as much as the question of the patient's surroundings and the severity of the disease. Among 50 diabetics he recalled 20 with tuberculosis, making 40 per cent. Von Noorden called attention to the fact that tuberculosis occurred in 25 per cent. of the cases. Dr. Mayer said he had been able to follow 168 cases in private practice. These cases did not include those seen in consultation or cases only seen occasionally. Among these 168 cases occurred 21 deaths; of these 21 4 were tuberculous. One was an individual of seventy years with hemoptysis; another was an individual of seventy-three years with no sign of tuberculosis at all except in the sputum; another was a young man, thirty-four years old, who contracted syphilis with his diabetes, the diabetes running a very rapid course; another was a patient aged forty-three, without symptoms of tuberculosis at all except the ordinary physical signs and the sputum. In a paper read before the Section six or eight years ago in a symposium, he said he mentioned the fact that diabetes and tuberculosis were commonly associated and also that one-fourth of the patients that died, died from other troubles.

Dr. Heinrich Sterne said he had made some interesting investigations regarding diabetes in New York City and had gone to the Board of Health and looked over the cases and tabulated them, and he found that of all the cases of

diabetes that were reported to the Board of Health in this city prior to six years ago, less than 8 per cent. died of tuberculosis. This showed that probably in New York City tuberculosis was not so commonly associated with diabetes as it was in Germany or in England. On the other hand, in this country a complication frequently met with, equally as common as tuberculosis, was pneumonia. Among the 21 deaths referred to, 4 died of acute pneumonia. Gangrene of the lungs, complicating diabetes, appeared to be more common in Germany and England than in this country. The statement by the reader of the paper in regard to facts was not exactly correct according to the latest investigations; it was not the intake of fats that produced acetone; experiments had been made by Von Noorden and others on that point, and it had been proven that the fats were the sheet anchor in the diabetic. If the fats produced acetone, or the mother substance, in the body, it must be the fats which can be washed out from the butter. Von Noorden went into this question fully and in only one or two cases was he able to demonstrate that the intake of fat produced acetone. If a given case of diabetes, complicated by tuberculosis, be deprived of fat, one took from the individual the very substance which was absolutely necessary for the diabetic.

Dr. Shively said, referring to the disinclination of the patient with diabetes to go to a sanatorium for treatment, that there were a number of such institutions abroad. The number of diabetics was small indeed as compared with the number of tuberculous in any community, but he thought there was a field of usefulness in the establishment of such institutions for diabetics, especially when they were of the progressive type. He said he only gave a theoretical objection to the fat diet. He said the only safe rule to go by was to treat the patient without too much regard for theoretical considerations.

Treatment of Neuralgia with Chloroform Subcutaneously.—Dr. S. Ormand Goldan described this method of treatment, which he had employed with success during the past ten years. The technique consisted in injecting pure chloroform in quantities varying from two to ten minims into the site of the neuralgic area with an ordinary sterilized hypodermic syringe with aseptic precautions. Superficial injections often acted with certainty even when the pain seemed to be deep seated. While the subcutaneous injection of chloroform was exceedingly easy of application, all patients would not submit to it. The method produced certain reactions which seemed alarming to some patients. In acute neuralgia, where the cause was easily determined, general medical treatment would usually prove effective. Where, however, all palliative measures had failed, the patient would be willing, as a rule, to submit to almost any treatment which would relieve him of his suffering, and in these cases the treatment with chloroform would almost always prove successful, in fact, almost magical, and for this reason he had termed the method specific. The class of neuralgia subjected to chloroform treatment he classed as follows: Supraorbital neuralgia, first branch; infraorbital neuralgia, second branch; mandibular neuralgia, third branch; torticollis, brachial neuralgia, intercostal neuralgia, sciatica, lumbago, inguinal neuralgia, coccygodynia, plantar and tendinous neuralgia.

Dr. Herbert S. Carter asked Dr. Goldan what the intervals were between the injections.

Dr. Goldan replied that the injections were given as often as the patient would permit. He had had patients return for further treatments. He recalled one patient with lumbago and who had been under various treatments; instead of getting better he got worse. After two or three visits to him Dr. Goldan decided to use his specific method and, curiously enough, when he left the office he did so walking perfectly erect and free from all pain. Some patients require injecting every other day. Dr. Goldan then presented two cases to show the results of his treatment.

Pulmonary Arteriosclerosis, with Specimen.—Dr. Harlow Brooks reported this case and showed a specimen. This was of interest because of the condition of the heart and lungs. The patient was a woman, thirty-six years old, with a negative family history except a history of hemiplegia. There was no history suggestive of syphilis, except one miscarriage. She presented herself because of a hemiplegia with the usual manifestations. Upon examining the lungs there were found scattered areas of high-pitched râles, and exaggerated breathing. She had a fibrotic form of chronic bronchopneumonia. Upon auscultation there were found a loud diastolic murmur and a fine systolic murmur at the apex. The patient died finally of chronic nephritis, with amyloid degeneration, dilatation of left heart and arteriosclerosis of the pulmonary artery. There was no microscopical evidence of syphilis. The condition found was a moderate arteriosclerosis of the pulmonary tree. There was an aortic lesion. There was an old and marked sclerosis of the pulmonary cells as well as a marked arteriosclerosis of the pulmonary artery, not only in the artery itself, but in its smaller ramifications. Throughout the entire lung tissue an enormous arterial thickening was present. Dr. Brooks gave two possible explanations for the conditions found. First, it might be due to syphilis which, for some unaccountable reason, attacked one system, the chief point of attack being the pulmonary artery. Second, there might have been a primary endocarditis, followed by an arteriosclerosis of the pulmonary tree. The changes in the pulmonary artery far exceeded those in other arteries of the body. Dr. Brooks' explanation was that there was first a primary disease of the right heart, with some valvular lesion, which terminated in a dilatation of the left heart. Following the endocarditis and the valvular changes there occurred a great increase in intrapulmonary pressure. There was quite a remarkable degree of hypertrophy of the walls of the right ventricle. This was the only explanation he could advance for the extreme degree of sclerosis present.

The Surgical Treatment of Alveolar Pulmonary Emphysema.—Dr. Charles Goodman and Dr. Siegfried Wachsmann presented this communication, which was read by Dr. Goodman. (See page 807.)

Dr. Rudisch said that he had occasion to look up the literature on this subject, and he found that Dr. Goodman differed with Freund somewhat as to the cause of the condition. Freund stated that emphysema was produced by a primary rigidity of the cartilages. Of primary interest was this rigidity of the cartilages, the second, third, fourth, and fifth, mostly on the right side, thus accounting for the distortion of the thorax seen in emphysema. He recalled one instance where, at the post mortem, upon opening the thorax, the lungs collapsed. In the ordinary cases produced by asthma, they did not collapse.

Dr. A. Jacobi said he was delighted to know that these patients could be operated upon, and in such a short time be so improved. He asked Dr. Goodman if these patients had been receiving any medicines at the time of operation or since.

Dr. Goodman replied that they had been receiving narcotics and medicines for their bronchitis, but not so much as previous to operation. They received one-sixth of a grain of heroin occasionally, only the first few nights, to relieve them of their pain, which resulted from the operation. They received iodide of potassium, heroin, and digitalis.

Dr. Jacobi said that this operation was on trial, and the outlook was favorable. But the time was too short to pass a fair judgment upon it, and he warned against its abuse. He could well imagine that many would attempt the operation in cases where it was not indicated. They should not operate upon every case of emphysema, whether primary or secondary. Dr. Jacobi wondered if they all knew who Freund was. Freund published his first writings in 1858; that was fifty years ago. In 1859 he wrote a paper

on ossification of the first costal cartilage in connection with the origin of apical tuberculosis. He was a man of superior qualities. He stopped writing on that subject for a time because he had the chair of Obstetrics and Diseases of Women in two different universities, one at Berlin, the other at Strasburg. Six years ago he returned to his original work. Four years ago he presented a new paper on the same subject, and he had been writing upon it ever since. That the cases presented by Dr. Goodman, operated upon such a short time ago, were not entirely well was self-evident. Freund said that rigidity of the thorax was the result primarily of an early ossification of the costal ribs; and, further than that, a change in the cartilages themselves. There was a final deposit of lime in the cartilages, as well as much thickening. The rigidity of the chest wall was not only the result of the ossification, but also because of the rigidity of the costal cartilages. These were the cases that Freund wanted to operate upon. Other cases should not be operated upon. If every case of emphysema was operated upon where the ribs and cartilages were normal, there would remain the same condition after. The majority of the cases they met with were the result of a chronic bronchial catarrh, with changes in the lungs, sometimes complicated with cardiac disease, etc. The presence of heart disease as such was not a contraindication. Dr. Jacobi said he could not imagine a case where at autopsy an inflated lung would bulge out, that would be benefited by any sort of operation unless it was the removal of large pieces from a large number of ribs. On the other hand, Dr. Goodman had told them that when the chest wall was opened the lung retracted. Here the emphysema was the result of rigidity of the chest; when the chest was opened the lungs did not bulge, but retracted. These were the two kinds of emphysema. He believed that, for the time being, they should refrain from operating upon those cases that did not result from any change in the bones. He feared the operation would be abused unless they operated only upon such cases. Many might be disappointed with the operation unless the cases were selected, and he did not want to see the operation consigned to the junk heap without a full and thorough trial.

Dr. GOODMAN said that in cases of pure emphysema with asthmatic complications local anesthesia might be tried. The technique he had outlined as a result of his experience could be employed under local anesthesia. He had already pointed out the fact that the ribs distinctly retracted; when the pleura was exposed at operation the lung could be distinctly seen to retract and to pull the ribs along at times. All the cases they had operated upon had shown a very decided improvement.

Post-Typhoid Sepsis.—Dr. FORBES R. MCCREERY reported a case of post-typhoid sepsis. An ordinary course of the disease occurred until the fourth week, when, instead of becoming normal, the temperature remained up, and became still higher in the fifth week, reaching 103°. The patient was twenty-one years old, and very much emaciated. He started feeding with solid food, and this worked nicely for a time, when, at the end of the fifth week, the temperature went to normal, and remained normal for four or five days. In the sixth week, the patient had chills, and continued to have chills and rise in the temperature for the next two weeks. The chills were very severe, lasting at times for hours. Nothing could be found to account for the condition. The patient was allowed to get out of bed with a temperature of 105°. In the seventh week there developed a phlebitis of the left popliteal vein, which cleared up in the course of a week. The temperature became normal in the eighth week, and the patient left the hospital. No malarial organisms could be found in the blood. The disease was not influenced by quinine as much as it would have been had there been a malarial organism present. There was a slight increase in the number of leucocytes.

A CLINICAL STUDY OF A CASE OF BRAIN TUMOR; OPERATION; COMPLETE RECOVERY.

By WILLIAM W. GRAVES, M.D.,

ST. LOUIS, MO.

INSTRUCTOR IN NEUROLOGY IN THE ST. LOUIS UNIVERSITY.

The results achieved in surgery of the nervous system are not sufficiently brilliant to cause widespread optimism in the medical mind. Indeed, the profession generally holds decidedly pessimistic views regarding the treatment of nervous diseases whether by medical or surgical means. This is not true, however, of most of those whose lines of work compel them constantly to deal with morbid states affecting the nervous system. Such are *usually* optimistic, but their optimism in surgery of the nervous system is founded not upon the many brilliant results, but upon the very few; and upon the palliation which may often be secured by surgical means. This is especially true of surgical therapeutics of brain tumor. The successes of surgery in tumor of the brain are indeed few as far as complete restoration is concerned, but when one considers the absolute and inevitable hopelessness of such cases without surgical intervention, and the possible palliation of indescribable suffering even when complete restoration cannot be obtained, these results, few though they be, are still sufficient to cause both the surgeon and neurologist to be optimists in this field of work. The problems confronting them are plain, but their solution is difficult. The problems briefly stated are these: First—*early and accurate diagnosis;* second—*proper surgical technique.* Brain tumor is usually localizable; therefore, an early and localizing diagnosis is always desirable if complete restoration is to be hoped for. If palliation alone is to be expected, precise localization is not absolutely necessary though always desirable. It may be stated, however, that tumor of the brain giving rise to symptoms indicating palliation will usually present unmistakable localizing symptoms. The presence of brain tumor, its location, its probable nature, and the surgical indications, whether extirpation or mere palliation, are problems the surgeon has a right to expect—the neurologist to attempt to solve. On the other hand, the neurologist expects, and the interest of the patient requires, the surgeon to be possessed of a degree of technical skill commensurate with the difficulties constantly met with in this field of work. The *ideal* would be a surgeon who is at the same time a neurologist. The difficulties encountered in surgery of the nervous system are so great that it is rapidly becoming, and justly so, a special department of surgery. The development of more men like Horsley and Balance in England; Krause and Borchard in Germany; Kocher in Switzerland; Chippault in France; and Keen, Cushing, and Frazier in America, will go a long way toward dissipating the pessimism in the general medical mind concerning surgery of the nervous system. By this statement, I do not mean to imply that only such men should operate on the nervous system—far from it—but I do mean that he who would do this work should have had some special training—not only special technical training, but also in the physiology, anatomy, and pathology of the central nervous system—in other words, he should have given the whole subject his earnest consideration before invading the brain or spinal cord with the same degree of assurance that he would the abdominal cavity. The surgeon and the neurologist are indispensable to each other at the present time in surgery of the nervous system. It is a field wherein they should both work shoulder to shoulder, and when it is tilled with earnestness and mutual consideration, their joint labor can only have the result of saving or prolonging many lives.

The case, the subject of this study, is one wherein the joint labor of surgeon and neurologist happily resulted in the relief of distressing symptoms and a complete restoration of function.

On September 25, 1906, I was asked by Dr. P. G. Paugh to see Mrs. B., age 50, in consultation. She had been under his observation for a few weeks, complaining of motor weakness of the right extremities, constant paresthesia of the right forearm and hand and a peculiar speech defect. The immediate history was to the effect that on the evening of September 23, 40 hours prior to my visit, the patient had been seized with a convulsion beginning in the right hand—extending to the arm, face, and leg on the same side of the body—covering a period of three hours and ending with complete loss of consciousness. Since the cessation of the convulsion, the patient had been totally and completely paralyzed on the right side and though consciousness returned early, she had been unable to speak, yet showing evidence of being cognizant of her surroundings, and of being able to understand everything said to her.

A physical examination at this time revealed an individual small in stature, prematurely aged, poorly nourished, and having rather a cachetic appearance. She was unable to make the slightest voluntary movement with either the right upper or lower extremity—voluntary movements of the other extremities were normal. The right lower face was distinctly paretic but the innervation of the upper face was in every way normal. The left pupil was slightly larger than the right, both pupils were symmetrical, reacted normally and with the exception of slightly defective convergence, the ocular excursions were normal. The cranial nerves were otherwise intact. An ophthalmoscopic examination revealed well nourished discs. Respiratory excursions, notably inspirations, were much less on right than on left with normal lung findings. Respira-

tions 20; pulse 80 per minute and regular, with nowhere evidence of arteriosclerosis, and the heart sounds were normal. The right forearm, hand, and fingers were distinctly cyanotic, and particularly the finger nails, which also showed distinct longitudinal corrugations. The muscle volume of the right extremities was somewhat less than the left. The upper extremity was in position of adduction and inward rotation at shoulder, semiflexion of elbow, pronation of forearm with slight flexion of wrist, adduction of thumb, and flexion of fingers. There was decided rigidity of adductors at shoulder, pronators and flexors of forearm and of flexors of wrist, and finger clonus was readily elicited. There was slight foot drop with outward rotation at the hip; distinct rigidity in hip adductors, in quadriceps and calf muscles with patellar and ankle clonus on the right. No disturbance in muscle tone in left extremities. The tendon reflexes were decidedly more active on the right than on the left. Babinski, Oppenheim, and Gordon reflexes were present on right with plantar response on left; abdominal reflexes absent in all divisions on both sides. Sensation to temperature, pain and touch normal throughout. Palpation of the skull revealed no scars, no abnormal depressions or elevations. The skull was not tender to palpation or percussion, but the percussion note in the left superior frontoparietal region, in an area somewhat larger than a silver dollar, was distinctly of lower pitch than in the corresponding area on the other side or in the adjacent area on the same side. The patient readily understood everything said to her, showed that she recognized various objects and their uses but was unable to name them or to repeat what was said to her. She would seemingly make the greatest effort to talk, and about the only words she could say were "I can't" and "yes, yes." From her daughter with whom she lived and from Dr. Paugh, the following facts were obtained as to her family and personal history:

Her father died before his 30th year of some acute illness, and the mother in her 65th year; three sisters died during childhood, two sisters—one older and one younger—are both healthy; family history otherwise negative. Patient had always been healthy and had never had serious illness. She was married in her 16th year, had given birth to four healthy children; one of these died when 3 years old; others are living and healthy—oldest 32, youngest 19. She had menstruated in her 12th year and menopause occurred 3 years ago. In her first confinement she had sustained a severe perineal laceration and had suffered since then with uterine prolapse and frequent micturition. Her husband had been dissipated and about 16 years ago he had struck her a violent blow over the top of the head with his fist; she was momentarily stunned but suffered no apparent inconvenience therefrom. She had never been subject to headaches, nausea, or vomiting.

Her first indisposition occurred in 1903 with sudden flushes of heat coming on at varying intervals; during these attacks she would be compelled to sit or lie for 15 or 20 minutes, and these were attributed to change of life, and she received no medical attention on account of them. During the summer of 1904 she began complaining of numbness in the thumb and index finger of the right hand and a few months later came home one day from a shopping expedition complaining of feeling sick and dazed and of inability properly to use the right upper extremity. After this a constant numb or unnatural sensation developed in the fingers of the right hand and the hand and fingers became reddened. This discoloration was at times quite noticeable, at other times less so, but the numbness was almost constant. For months, she used liniments and massage, and in April, 1905, upon medical advice, spent three weeks in Hot Springs, Ark., taking baths daily, but obtaining no relief. Her symptoms increased, and in the summer of 1905 she became suddenly ill during the night, and a physician, who was called and whose name could not be remembered, diagnosed, "blood clot, pressing on the brain," and advised operation. She was paralyzed on the right side of the body and was speechless for 36 hours, but recovered within three days, and in addition to the weakness in the right arm, which became more pronounced after this illness, she noticed a tendency to drag the right foot in walking. A few weeks following this attack, while stepping out of a bath, she fell and bruised her right shoulder and arm. She consulted two prominent physicians at this time, submitted to an *x*-ray examination, but nothing abnormal was found about the right shoulder joint where the trouble was believed to be located. The weakness about the right upper extremity having progressed to that degree that she could no longer attend to household duties, she came to live with her daughter in November, 1905. During the last week of December, 1905, she had an attack of what was thought to be apoplexy. The muscles of the right side of the face and body became convulsed, eyes turned upward and to the right, respirations labored. She frothed at the mouth and voided urine during the attack, the whole attack having a duration of about 15 minutes; and within a period of about half an hour, she had a similar attack in every way, lasting 35 or 40 minutes. During the succeeding 24 hours, she was absolutely speechless, though conscious; she seemingly understood what was said to her and swallowed medicine and liquid nourishment. The right arm and leg were totally paralyzed and the face was drawn to the left for about 36 hours. She remained in bed for a week and after a couple of weeks seemed nearly as well as before the attack, excepting that the weakness seemed rather more pronounced in the right extremities than it had been before. In the beginning of 1905, the patient developed a peculiar speech defect. In the midst of a sentence, she would suddenly stop with the words: "Oh! I can't talk," though she would seemingly make the greatest effort to continue. After a variable period, from a few seconds to five minutes, she would suddenly begin talking again.

At about the same time the speech defect developed, the patient began complaining of a frequent recurring momentary inability to use the right upper extremity and especially the hand. If when she attempted to make a fist or grasp an object, and if at other times she attempted to extend the fingers or to release an object she would be unable to do so. This disturbance would frequently occur coincidently with the speech defect, but usually independently of it and was of more frequent occurrence than the speech defect.

At about 5 P. M. September 25, a few hours after my visit, the patient had a rightsided convulsion involving only the hand and face and having a duration of about 15 minutes. She remained free from convulsions until October 4, when she had another attack similar to that of September 25, excepting that it was preceded by a one-half hour period of intense nervousness. The patient was seen by me daily and about three days after the

attack of September 23, was able to make feeble movements with the right extremities and to speak both spontaneously and by repetition. She was at first decidedly paraphasic, but always recognized her errors. She made rapid improvement in all respects, and within 10 days was able to walk about the room and had fair use of the right upper extremity. During my visits, I had frequent occasion to observe the sudden impediment in speech and motility previously mentioned. The following observations were made on October 4, 1906: When the patient was told to make a fist, she was momentarily unable to do so, and instead made slight adduction movements at the shoulder and then a little later was unable to make these movements; still a few minutes later, she was able to abduct the arm to a horizontal position, to make limited extension and flexion movements at the elbow, pronation and supination of the forearm, and all normal movements of the wrist and fingers, though these movements were weak. She was able to make all normal movements of the right lower extremity, though in a slow and hesitating manner. On this occasion, while the patient was talking about her trouble, she suddenly ceased in the midst of a sentence and for the next five minutes was unable to utter a sound though apparently making every effort to talk, during which irregular and sighing respirations occurred and she appeared to be worried and uncomfortable. Her daughter finally said: "You surely can say yes or no, can't you?" when suddenly the patient's face brightened with a smile and then, and in an explosive manner, she repeated several times "you can say yes or no, can't you?" The patient then resumed the thread of conversation in which she confirmed the statement that she had never had headache, nausea, or vomiting, but had frequently complained of momentary dizziness and at such times had often had a thumping in the left side of the head, and it had often been so distinct that she imagined others could hear it, too. Patient also stated that she had frequently experienced shooting pains in the right arm, especially in the fingers, but in no other part of the body. The pain was paroxysmal and was always most severe when the hand showed the greatest discoloration.

The result of an ophthalmoscopic examination on September 27, 1906, by Dr. John Green, Jr., was as follows: "Both nerve heads clean cut, tinted a healthy pink throughout; retinal vessels presented no deviation from the normal either in caliber or course. In brief, the ophthalmoscopic picture was that of a well-nourished optic nerve head and retina."

Dr. Paugh had made repeated examinations of the urine since patient had been under his observation and also since the attack of September 23, and had never found any abnormal condition.

On October 4, while inspecting the patient's right hand, it was noticed for the first time that irregular clonic contractions were present in the extensor tendons of the fingers, especially of the index and middle fingers, in the short extensor for the thumb and the interosseous primus muscle. These were not constant, but occurred in "little spells" and could be felt when they could not be seen. Patient stated that she had frequently noticed these jerkings about the back of her hand ever since the numbness began, and she had never noticed them in any other part of the extremities. Repeated observations failed to disclose these contractions in any other muscles. At this time there was no sagging of the right shoulder and she could elevate her shoulders equally. The defective innervation in lower facial had entirely disappeared, her gait was only slightly paretic on the right, and ankle and patellar clonus had disappeared; there was no longer rigidity in the calf-muscles, but it was still slightly present in quadriceps and adductor groups, also in the adductors of the shoulders, flexors and pronators of the forearm and was especially marked in the palmaris longus muscle. On passively extending the wrist, the tendon of this muscle stood out prominently and clonus was always readily provoked. The difference in the tendon reflexes between the two sides of the body was still pronounced. Babinski, Oppenheim and Gordon reflexes were still present on the right. The abdominal reflexes were still absent in all divisions on the right, but were now present on the left. Sensation in all qualities including posture and form was normal. The pupils were now of equal size and as at first examination, reacted in every way normally.

Comment.—The immediate problems presenting themselves on September 25, 1906, were: First, What was the cause of the convulsion of two days ago, the total paralysis of the right extremities and of the complete motor aphasia accompanying it? Second, As to the prognosis.

A physician being suddenly called into the presence of an individual presenting the condition of our patient on September 25, 1906, and being unable to obtain any history other than that pertaining to the immediate illness, would probably find the solution of these problems very difficult if not impossible. With such limited knowledge, he would probably make the diagnosis apoplexy and give a guarded prognosis. Certainly, such a diagnosis would seem the most probable since cerebral hemorrhage, thrombosis, or embolism occurring in certain localities might account for the convulsive seizure, the total paralysis with attending phenomena, and the speech defect; but a careful analysis of the findings would render such a diagnosis and prognosis highly improbable.

The findings militating against these conclusions were: First, the totality of the paralysis of the right extremities with decided weakness in lower facial muscles still persisting after 40 hours, during which time the sensorium had been entirely free; second, the absence of the slightest weakness in upper facial muscles with entire freedom of the 12th and other cranial nerves; third, the vasomotor trophic disturbance about the right upper extremity.

Such findings did not preclude the possibility of an acute process having taken place such as hemorrhage, thrombosis, embolism, or uremia, but they did render such a diagnosis highly improbable; especially so, since as is well known, clonic convulsions persisting over a considerable period of time are frequently followed by total paralysis in the same muscles for a variable period of time after the cessation of the seizure. The immediate history was to the effect that 40 hours previously our patient had been suddenly seized with clonic contractions in the muscles about the right hand, that the convulsive movements had rapidly extended to the upper arm, face, and lower extremity, and that all of these parts were violently convulsed for a period of three hours, and that since the patient had regained consciousness, she had been unable to make the slightest voluntary movement of the right extremities and had been absolutely speechless. While it must be admitted that both apoplectic and uremic states may be ushered in with muscle

twitchings, they practically never have the character, mode of progression, and the persistence as those which had occurred in our patient. Furthermore, for either apoplectic or uremic states to be followed by such total and persistent paralysis with free sensorium almost from the cessation of the seizure would hardly be conceivable. The normal urine, heart and vascular findings and free sensorium absolutely precluded the possibility of a uremic condition and at the same time rendered the diagnosis of apoplexy very improbable.

From these considerations, based wholly upon the immediate history and physical findings, the diagnosis of apoplexy of whatever causation, became less and less tenable and a more probable diagnosis, *i.e.* "exhaustion paralysis" following a Jacksonian fit dependent upon a previously existing condition, became more and more urgent. The vasomotor and especially the trophic disturbances about the right finger-nails added additional support to such conclusions. These conclusions became practically certain when taken in connection with the previous history of our patient. From this we learned, that her first symptoms occurred three years ago and consisted in flashes of heat, accompanied by what must have been suddenly occurring dizziness, since at such times she was compelled to either sit or lie down. In the course of time paresthesia and vasomotor disturbances developed about the right hand, and a little later peculiar momentary motor and speech inhibitions and permanent weakness of the right extremities ensued. Furthermore, it was ascertained that she had had two distinct seizures similar in all respects to the seizure of September 23, 1906, excepting as to duration, and that in both instances there had been complete paralysis of the right side of the body accompanied by a total motor aphasia; that these conditions invariably subsided, so that within a period of two weeks at most the patient had regained her usual state of health and the only change noted was that the weakness of the extremities became a little more marked after each attack.

Therefore, a consideration of the immediate and previous history of the patient, in connection with the findings of the physical examination, rendered the diagnosis *exhaustion paralysis*, following a Jacksonian fit, the only tenable one. The same considerations made it highly probable that the recent Jacksonian fit as well as others preceding it, the paresthesia, the vasomotor trophic disturbances, the character of the persisting weakness, the peculiar momentary motor and speech defects were all dependent upon an essential lesion involving the left cerebrum and having its location in the Rolandic area involving particularly the ascending frontal convolution and to a less extent the ascending parietal convolution. Furthermore, that the portion of the Rolandic area, commonly called the arm center, was most involved. These diagnostic and localizing conceptions were rendered positive by the developments in the case in the succeeding days following the seizure of September 23. It will be remembered that the patient rapidly regained her previous state of health, that she was able to confirm the evidence given by Dr. Paugh and her daughter concerning her history; that we were able to detect the presence of minute Jacksonian spasms in certain muscles about the right upper extremity, and that the patient informed us that she had been conscious of the spasms for more than two years. No more valuable information could be desired than the presence and the history of these spasms in confirming both the diagnosis of a lesion and its exact localization. Both were strongly supported by the presence of decided dullness to percussion in a limited area in the left superior frontoparietal region.

Having determined the presence of a lesion in a certain location, the question naturally arose, what is its nature? The determination of the exact nature of a lesion within the cranial cavity is one of the most difficult problems in neurology. Upon a more or less correct solution of this problem will depend our efforts in relief, whether medical or surgical, whether curative, palliative, or radical. A solution of the problem of the nature of the lesion responsible for our patient's symptom-complex was materially aided by the history, the nature of the speech defect, and motor weakness. It must have been a constant and progressive lesion but at the same time both irritative and variable. While it is true that a certain degree of motor weakness was present, yet the lesion must have been one, to say the least, not rapidly destructive. Indeed, the patient was able to make almost every normal movement at times, though in a paretic manner. In a destructive lesion, let us say, that has already destroyed a motor area or materially interfered with its integrity, certain synergic movements will be found to be impossible. For example, with a more or less complete destruction of the center for the upper extremity a normal fist cannot be made. Our patient could make this movement at times as well as other normal movements of the right upper extremity. The lesion then, strictly speaking, had not yet become a destructive one. What, then, could have been the nature of the lesion which, after a period of three years, had not yet absolutely destroyed any part of the Rolandic area and which was nevertheless progressive and one which was constantly irritative and variable? One could hardly think of any lesion meeting all of these conditions other than a new growth. Assuming this view to be correct, it must have been a new growth neither cortical nor subcortical, but one growing primarily either from the bony or other coverings of the brain. It could not well have been a tumor growing from the bony coverings because the outer table of the skull would certainly have been invaded and for the further reason that a bony tumor could hardly have given rise to any but a destructive brain lesion within a period of three years. There are really but two forms of growth, either one of which might be made responsible for the above-mentioned requirements in bringing about our patient's symptom-complex; one a cavernous-angioma, the other an arachnoidal cyst. The volume of either might be variable yet constantly assuming greater proportions and either, therefore, might account for our patient's symptoms. Head trauma is frequently found in the histories of brain tumor cases, and it will be remembered that 16 years before, our patient had received a stinging blow on the top of the head. Brain tumor usually gives rise to two classes of symptoms: the one called *general*, the other *focal*. In our patient, as we have seen, we had exquisite focal or localizing symptoms but absolutely no general symptoms. The classical general symptoms of brain tumor are severe, often excruciating headache, projectile vomiting, and choked disc; none of these symptoms had ever been present in our patient. General symptoms are frequently in the beginning the only symptoms of brain tumor and they are rarely absent during the course of the disease. They are indeed so constant that without the presence of one or more of them, one is rarely justified in

making the positive diagnosis *brain tumor*. Yet despite this fact, such a diagnosis seemed the only tenable one in our patient and the remaining problem, namely, the possibility of relief, came up for consideration. If relief were to be had, it could only be surgical, and it was naturally not a question of palliation but possible extirpation. From the preceding considerations, it seemed highly probable that radical relief might be secured. Dr. Frank R. Fry kindly saw the patient with me in consultation on October 7, confirmed my deductions, and agreed with me as to the surgical indications in the case. The patient was also seen by Dr. T. C. Witherspoon, and on October 9, 1906, the patient entered the Mullanphy Hospital.

Operation:—The probabilities of radical relief were so great that Dr. Witherspoon elected to do the bone-flap operation. The patient was placed on the table on October 10 under ether anesthesia. A flap comprising three-quarters of a circle was laid in the left frontoparietal region having dimensions of four inches horizontally and three inches vertically and extending to the middle line above and having its base in the mid-temporal region below. Upon turning the bone flap downward, decided tension of the dura was noted near the anterior margin of the opening. Upon deflecting the dura

Fig. 1.—Showing the circumscribed area in which "dullness" was found at the first examination and repeatedly verified. Drawn from a photograph.

at this point, a clear and thin walled cyst was found through which the normal appearing, though greatly depressed convolutions could be seen. The cyst was almost immediately underlying that area of the skull in which dullness had been previously mapped out and having the dimensions and configuration of a small hen's egg (Fig. 1). The larger end of the cyst was overlying the ascending frontal convolution, the other portion over the first and second frontal convolutions and the pre-central sulcus was immediately beneath its center. The ascending frontal convolution was pushed backward against the ascending parietal by the cyst wall, causing a distinct concavity in both. No attempt was made to remove the entire wall of the cyst, which, after its upper portion had been removed, collapsed and could not be dissected out. The curcial incision in the dura was accurately united with gut sutures and without drainage of the cyst cavity; the bone flap with attached scalp was replaced; but since there had been considerable oozing from the diploë, a small rubber tissue drain was inserted between the dura and the bone flap at the posterior inferior angle of the wound and the scalp was united with gut sutures. The whole operation was completed within 45 minutes and the patient was returned to her bed in a state of rather profound shock, but she reacted in a very short time. The rubber tissue drain was removed on the third day, and upon its removal quite a quantity of bloody serum followed it. The wound was not seen again until the twelfth day when the dressings were removed and complete scalp-union had taken place; after this only a protective dressing was employed and the patient returned to her home on the nineteenth day following the operation. After the change of dressings on the third day, the case no longer presented surgical interest, but many interesting neurological phenomena occurred in the succeeding days following the operation, the most striking of which follow:

Post-Operative Phenomena and Present Condition.—When the patient returned to consciousness, she had complete motor aphasia and was unable to make the slightest voluntary movement of the right extremities; and in about six hours after the operation, Jacksonian fits developed, invariably starting in the right thumb and index finger, rapidly extending to the muscles of the upper extremity, shoulder, and face, but rarely involving the lower extremity. During the fits, the muscles about the orbit and brow on both sides, but only of the right lower face, were violently convulsed and the globes oscillated in a clonic manner from the primary to the extreme right lateral position. For the next six or eight hours, there was but little intermission in these seizures and it might well be said, the patient was in a state of Jacksonian status epilepticus. These fits diminished both in intensity and duration, the last occurring on the fourth day after the operation, and she has remained entirely free from them up to the present time. Twenty-four hours after the operation, the patient's speech had returned; she was, however, decidedly paraphasic but could make herself understood. She could also feebly move the right lower, and to a less extent, the upper extremity. It was noted at this time that every vestige of rigidity had disappeared, that the tendon reflexes on the right were less active than at any previous examination, that the abdominal reflexes were again absent on both sides, and that Babinski and Oppenheim reflexes were absent, with Gordon's reflex still present on the right. Forty-eight hours after the operation the patient became absolutely aphasic, she could neither make any effort at talking nor could she understand anything said to her. Effort was made to communicate with her by written and printed symbols but met with failure and the only possible way of communicating with her was by pantomime which she seemed readily to understand. It was believed by both Dr. Witherspoon and myself that these new aphasic symptoms as well as the return of former ones were due to retention of possible oozing, accumulating beneath the bone flap, and it was decided to investigate the matter on the following day in the event of no amelioration occurring within the succeeding few hours. No improvement being noted in the aphasic symptoms, the rubber tissue drain was removed on the following morning with the result as stated above, and after this time the speech defect, both sensory and motor, rapidly disappeared; and since the twentieth day following the operation the patient has remained free from every aphasic symptom. During the first 24 hours after the operation the patient complained of intense pain in the right upper extremity, especially about the finger tips and nails, and particularly the thumb. On examining the extremity, the previously existing hyperemia had almost disappeared and the finger nails were paler than they had ever been before. A large bleb or blis-

ter formation was found involving the radial, palmar, and tip surfaces of right thumb. This increased from day to day and eventually involved fully one-half of the surface of the distal phalanx. Within the next seven days, similar blebs appeared about the tips of index, middle, and ring fingers in the order named. For some hours preceding the formation of each blister, the patient complained of excruciating pain in tip of finger next to be invaded, and after the formation of a blister, the pain became less. When the blisters first appeared they were translucent, but as time went on they became a brownish-black color, hard and dry, and were cast off in the next three or four weeks (Fig. 2). The finger tips even beneath the sloughs, remained exquisitely tender and painful for some time. The patient continued to complain of un-

Fig. 2.—Thee apparance of the thumb and finger tips on the twentieth day after operation.

natural sensations in the hand and fingers for several months following the operation, and while immediately following the operation the previously existing hyperemia of the forearm and of hand was noted to be decidedly less, it did not entirely disappear for several months.

Since the patient left the hospital she has never had a recurrence of her former momentary motor and speech inhibitions. She rapidly regained the full use of her right extremities, is now able to sew, to do the finest needle work, and she experiences no weakness about the right side of the body. Her only complaint now is occasional shooting pain in right little finger. I shall not at this time dwell upon the probable causation of the postoperative neurological phenomena as recited above, but suffice it to say that the necessary exposure and manipulation of the cortex incident to the operation, the processes incident to healing, and the re-establishment of the new relations between the brain and its coverings might well be considered as being responsible for them.

The patient was seen by me only a few days ago, September 30, 1907, when the facts as just recited pertaining to her general condition were ascertained. The physical examination revealed a thoroughly well nourished, contented, and happy individual. Her gait was in every way normal and every vestige of the former hemiplegic attitude had disappeared. Her pupils were equal, reacted promptly, and the ocular excursions, except in convergence, were normal. This slight bilateral defect in convergence was as at the first examination and is probably inherent with this patient; at least the brain tumor was, in my opinion, in no way responsible for it. The patient was able to make every normal syngeric movement with the right extremities, and while the coarse strength in these were slightly less than in those on the left, the difference was proportionate to the muscle volume between the two sides. Every vestige of rigidity had disappeared and no twitchings could be detected in the extensor muscles for fingers and thumb. The skin of the right hand and forearm was no longer cyanotic; the corrugations of the finger nails were less prominent; the finger tips, the former seat of blister formation, were somewhat atrophic but no longer hypersensitive; the tendon reflexes were practically equal; the pathological toe reflexes were all absent and the abdominal reflexes were now present and equal in all divisions on both sides. An ophthalmoscopic examination by Dr. John Green, Jr., made five months after, showed exactly the same normal picture as before the operation.

In conclusion, let me revert to the pessimism now existing in the general medical mind, in reference to surgery of the nervous system. The case just reported is an illustration of the possibilities of neurological diagnosis and neurological surgery, and upon such possibilities our optimism finds a firm foundation. Indeed, in any medical endeavor whatsoever there is no place for the spirit of pessimism and least of all in surgery of the nervous system.

Metropolitan Building.

PNEUMOTHORAX AND POSTURE; THE IMPORTANCE OF THE ABDOMINAL POSTURE IN OPERATIONS ON THE PLEURA AND LUNGS.*

By CHARLES A. ELSBERG, M.D.,

NEW YORK.

ADJUNCT SURGEON, MT. SINAI HOSPITAL.

The danger of the sudden entrance of air into the normal pleural cavity has, more than anything else, impeded the progress of the surgery of the lung and of the other intrathoracic viscera. There are other dangers, such as that of great susceptibility to infection, but the grave symptoms from acute pneumothorax are those that have to be most considered. Much careful experimental and clinical work has been done to overcome and guard against the dangerous respiratory embarrassment which is apt to ensue.

When there are adhesions between the visceral and parietal layers of the pleura, the danger from

*Read at the meeting of the Surgical Section of the New York Academy of Medicine, April 3, 1908.

the sudden entrance of air when the chest is opened is a small one. Such adhesions are, fortunately, present in from 50 to 75 per cent. of the cases with inflammatory processes, such as abscess and gangrene of the lung. Unfortunately, however, one is never able to say with certainty in any one case whether or not adhesions are present.

Much work has been done and many methods devised to produce these adhesions. Some have advised the injection of irritating fluids; others have exposed the parietal pleura and cauterized it with zinc chloride, nitrate of silver, iodine, etc., so as to cause a localized inflammatory process; others have sutured the visceral and parietal pleuræ together without opening the pleural cavity. The sutures were soaked in turpentine or other drugs to cause adhesive inflammation. Witzel recommended that the pleural cavity should be filled with fluid before the pleura is incised. Still others have incised and packed the opening at the first sitting. All these methods have been proven to be uncertain, as adhesions may not be formed in spite of their use.

Délagenière was the first to call attention to the fact that after the pleural cavity has been opened, one can often prevent the occurrence of serious symptoms from the sudden collapse of the lung by quickly grasping the lung and drawing it into the wound, fixing it there by a few sutures.

The greatest advance has been made by Sauerbruch and Brauer in Germany; the former has devised a large and complicated cabinet in which the pressure is negative corresponding to the normal intrapleural pressure, the patient's head being outside of the cabinet. The latter has devised an apparatus by which the patient breathes compressed air. By both of these methods the lungs remain distended even when a very large opening is made into the chest. While both methods constitute distinct advances, they have been adopted by only a small number of surgeons on account of the complicated apparatus required and the large expense. The subject requires further study and investigation.

During the past year I have done some experimental work on dogs in the Department of Physiology and Pharmacology of the Rockefeller Institute. I desire, in this place, to make acknowledgment to Dr. S. J. Meltzer for much aid and many suggestions. The results obtained from my experiments I later applied in practice.

Much work has been done on the subject of pneumothorax, and the symptoms which follow the sudden entrance of air into the normal healthy pleura have been studied experimentally in dogs. Most of the animals died from the pneumothorax when a large opening was made. Gluck lost all of the dogs he used; Biondi lost four of five; Block, Marcus, Schmidt, Pourrat and Rodet, Tuffier, Murphy, Quenu and Longet had similar experiences.

In some recent experimental investigations of open pneumothorax I obtained similar results. Many of the dogs either died suddenly as soon as an opening into the pleura was made, or a violent expiratory dyspnea ensued, soon followed by rupture of the mediastinal septum, double pneumothorax, and death. The method of operating on the dogs was the following: The animal was given a hypodermic injection of morphine, and a few hours later was anesthetized with ether; tracheotomy was performed, a cannula inserted, and the administration of ether continued through the cannula. One or more ribs were resected, the intercostal muscles divided, the pleura exposed, and a small opening carefully made in it and gradually enlarged. In a number of the animals the pressure of the inspired and expired air was roughly measured by allowing the animal to breathe into a large bottle, the tube leading to it from the tracheal cannula being connected by means of a T-tube with a water manometer.

If a small opening (1 to 5 mm.) is made in the right or left pleura of a dog which is lying on its back, or on its right or left side, the animal will in most instances continue to breathe well, although the amount of inspired and expired air will be less than (about two-thirds of) the normal. That such an animal is very sensitive to the slightest influence which disturbs the breathing is shown by the fact that if the animal is deeply under the anesthetic, clamping the trachea for part of a minute will bring on the dyspnea; if the dog is not deeply under the anesthetic, the struggling of the animal or irritation of the cornea, mucous membrane of the nose, etc., will bring it on.

While most dogs stand a small opening well, sudden heart stoppage or dyspnea and death will follow in some instances. The larger the opening, however, the more likely is the occurrence of serious interference with respiration. In almost all of the animals in which the size of the opening approached to or exceeded that of the diameter of the trachea, dyspnea and death followed. No matter how slowly and cautiously the opening was made, typical expiratory dyspnea ensued, the heart became irregular and weak, the mediastinal septum bulged into the opening with each violent expiration, and rupture of the septum and double pneumothorax or sudden stoppage of the heart occurred. Nor did it make any difference in what part of the chest the opening was made, whether on the right or left side, near the apex or base of the lung, near the sternum or vertebral column. When, however, the animal was operated upon while lying flat on its belly, very different results were obtained. When the dog is lying on its belly, not only can a small opening be made and the dog continue to breathe like a normal animal, but even a very large opening (2 to 4 cm.) can be made, and breathing go on regularly and quietly, almost if not quite like the normal. Even one-half of one chest wall can be removed and the animal survive. Furthermore, if a dog on its back, with an opening in its chest 1 cm. in diameter and with typical violent dyspnea due to the pneumothorax, is turned on its belly, the breathing will often become regular and quiet again, and the pressure of air breathed in and out will be found to be several times as great as when the animal was on its back. On the other hand, a dog on its belly with a large opening in one pleural cavity and breathing quietly, can be brought into a condition of grave dyspnea and asphyxia by turning it on its back. Sometimes it is even possible to resuscitate an animal that has stopped breathing by thus turning it on its belly.

A dog on its back will sometimes stand a double pneumothorax when the opening in each pleura is a very small one, not more than 1 or 2 mm. in diameter and very slowly made. But with the dog on its belly, an opening almost 1 cm. in diameter can sometimes be made in each pleura, if cautiously done, and the animal will often continue to breathe and survive for hours. The amount of inspired and expired air in such an animal is surely small as compared with the normal, but it is apparently sufficient to keep the animal alive.

The explanation of this great difference between an animal on its belly and one on its back with an open pneumothorax, is not an easy one. The fol-

lowing considerations and experiments are offered as a preliminary contribution to a solution of the problem.

The two pleural cavities are separated by the layers of the anterior and posterior mediastinal septa. Between the two lies the heart. In the dog the posterior seems to be somewhat tougher than the anterior, and somewhat more fixed and tense. With violent respiratory movements, it is the anterior septum which more especially flaps to and fro and bulges when an opening in the pleura has been made, and it is the anterior septum which is so apt to rupture and thus cause double pneumothorax and death of the animal. When the dog is on its back, the heart falls backward and the bulging of the anterior mediastinal septum is made more easy. It is different when the animal is on its belly. The heart falls toward the anterior chest wall and thus supports the anterior septum; hence the flapping of the septum, the interference with the respiration of the lung on the sound side, the bulging on expiration on the open side, cannot so readily occur. The following experiments, which I have repeated several times, are, I think, of importance in this connection.

After several ribs had been resected and before the pleura was opened, with the dog *lying on his back,* the pericardium was attached to the anterior chest wall by a suture, so that the heart was pulled forward. A very large opening could now be made in the pleura, almost as large as when the animal was on its belly, without causing the occurrence of serious symptoms. The moment, however, that the stitch was cut and the heart allowed to drop backward, the typical pneumothorax symptoms appeared. In a second dog, *lying on his belly,* the pericardium was attached to the posterior chest wall by a stitch before the pleura was widely opened. The heart could, therefore, not drop toward the anterior chest wall. When an opening was made in the pleura of this animal, the typical pneumothorax symptoms started. They ceased soon after the stitch was cut and the heart allowed to drop toward the sternum. In this way it was often possible to reverse conditions; to put a dog with an open pneumothorax on its belly into the conditions of one on its back, and *vice versa.*

From the above experiments, the conclusion may be drawn that in dogs, at least, pneumothorax is better borne when the animal is on its belly than when in any other posture. Also a pneumothorax is much better borne when the animal is deeply under the effects of the anesthetic.

These results I then applied in my work on the II Surgical Service (Dr. Lilienthal) at Mt. Sinai Hospital. All of the patients in whom operations were performed which required the opening of the pleura, were operated upon lying flat on the abdomen. Care was taken that the patients were deeply under the anesthetic at the moment when the pleura was opened. Operations on the lateral or posterior aspects of the thorax could be done with ease. The patient was laid flat on the belly with the head turned to one side or supported beyond the end of the operating table so that the anesthesia could be given without trouble. The position did not interfere with the operator or assistants. In this posture I have operated upon a large number of patients with empyema, upon two patients with abscess of the liver, upon three with subphrenic abscess, and upon one with a bronchiectatic cavity in the left lung. In all of the last-named patients the pleura had to be opened. The patients in whom a normal pleura had to be opened showed unusually few untoward symptoms when the opening was made and air was allowed to enter the pleural cavity. In the patients in whom an operation for empyema was done, it was noted that with only one exception the coughing and interference with breathing, regularly observed when the opening in the pleura is made for this affection, was entirely absent.

While these cases are too few to be conclusive, they seem to demonstrate that what is true for dogs is also true in this respect for the human being, and that there are decided advantages in operating upon these patients in the abdominal posture.

I believe that those who try this simple procedure will soon appreciate its manifest advantages. It is a very simple method of safeguarding our patients a little more in our intrathoracic operations, and may be used in conjunction with other methods.

A REPORT OF THIRTY-ONE CASES OF CONGENITAL DISLOCATION OF THE HIP JOINT REDUCED BY MANIPULATION.

By EDVILLE GERHARDT ABBOTT, A.B., M.D.,

PORTLAND, ME.

The object of publishing this report is not to present any radical departure from the familiar method of reducing congenital dislocations of the hip-joint by manipulation, but merely to place the work on record.

The ages of the patients varied from two to thirteen years, and, as usual, the greater number were females. Twenty-nine cases were unilateral and two were bilateral. The operation performed was the same as that described by Lorenz, with the exception that, in some instances, the plaster-of-Paris spica was extended below the knee in order to better control the after position of the limb. (Whitman: Orthopedic Surgery.) In three cases weight-traction was used preliminary to the reduction.

Case I. Girl, two years of age, dislocation of left hip, three-fourths of an inch shortening. The reduction was easily accomplished, and a plaster dressing applied, which was worn for four months. The successive spicas were applied at intervals of three months, the limb being lowered each time until it was brought to a normal position at the end of two years. Examination at that time showed limbs of equal length, slight eversion of the foot due to a twist in the neck of the femur, and slight limp. Subsequent examination, one year later, showed some improvement in the eversion of the foot, gait normal, and the joint in an anatomical position.

Case II. Girl, three and one-half years of age, dislocation of the right hip, shortening 1¼ inches. Reduction was accomplished with some difficulty, and, owing to the shallowness of the acetabulum, the replacement was very insecure. At the first change of the plaster spica it was noticed that the head of the bone had slipped forward beneath the anterior inferior spinous process. There was, however, so little shortening that no attempt was made to replace the head within the acetabulum. Spicas were worn for eight months with a final result as follows: One-third inch shortening, very slight limp, and anterior displacement of the head.

Case III. Girl, three years of age, dislocation of both hips, marked lordosis, extremely awkward gait. Reduction was readily accomplished, and the patient was removed from the Maine General Hospital in a few days. The child was of an extremely nervous temperament, and some member of the family re-

moved the spica in a short time. The result was an anterior displacement of both hips, with marked improvement in the gait.

Case IV. Girl, nine years of age, dislocation of the left hip, shortening one inch and three-fourths. Reduction was accomplished with much difficulty, as the patient was well developed. Spicas were worn for eighteen months, with a result as follows: One-third inch shortening, nearly normal gait, and anatomical position of the joint correct. Subsequent examination some four years later showed joint in position with improvement.

Case V. Girl, age eleven, dislocation of the left hip, one and one-half inches shortening. In this patient preliminary extension was employed, and reduction was easily made at first attempt. Plaster spicas were worn for twenty months, with the following results: One-third inch shortening, very slight limp, and head of femur firmly held in the acetabulum.

Case VI. Boy, four and one-half years of age, dislocation of the right hip, shortening three-fourths of an inch. Reduction easily accomplished, but the acetabulum was found to be very shallow, and it was with great difficulty that the joint was held in position while the plaster was applied. The first spica was worn for six months, and, when removed, the head of the bone was found to be again dislocated posteriorly. Another operation was advised and performed with a final result of an anterior dislocation. The gait was so nearly normal, however, that nothing further was attempted.

Case VII. Girl, aged eight years, dislocation of the left hip, shortening one inch, extreme intoeing. Reduction was easy, and joint very secure afterwards. Patient wore spicas for sixteen months with a final result as follows: one-fourth of an inch shortening, normal gait, and joint in correct position.

Case VIII. Girl, eleven years of age, dislocation of the left hip, shortening one and one-fourth inches. Reduction was accomplished with difficulty after repeated attempts, and the joint was very unstable. When the first spica was changed, the joint was found to be dislocated again posteriorly. Another reduction was made, but at the next change of plaster the bone was found anterior to the acetabulum. Nothing further was attempted in this case, as the gait was much improved and the condition of the patient at the time did not warrant another operation.

Case IX. Boy, six years of age, dislocation of the right hip, shortening one inch. The capsule of the joint in this case was extremely lax, and it was possible to replace the head without an anesthetic, but the muscles were so shortened that the limb could not be placed in a favorable position, therefore it was necessary to administer ether. The acetabulum had but little depth, and considerable difficulty was experienced in holding the joint in a normal position while the plaster was applied. Successive spicas were worn for sixteen months, with a marked improvement over the first condition, but the joint was not in an anatomical position. An open operation was repeatedly advised, but refused.

Case X. Girl, aged eighteen months, dislocation of the left hip, shortening three-fourths of an inch. Reduction was easily accomplished and limb placed in plaster. At the end of six months the joint was so firmly fixed in a normal position that the spicas were discontinued. The result was the best obtained in this series of cases. The shortening was less than one-fourth of an inch, and the gait at the end of the first year after operation was normal.

Case XI. Girl, three and one-half years of age, dislocation of the left hip, shortening one inch, marked twist in the neck of the femur. Reduction was made with some difficulty, as the capsule prevented the head from easily entering the socket. Plaster in this case was worn for eighteen months. The result was good, with the head in the correct position. Eversion of the foot was pronounced after the foot was brought to a normal position, but two years later this deformity was much less apparent.

Case XII. Girl, eleven years of age, dislocation of the right hip, shortening one and one-half inches, with considerable deformity of the head. Reduction was accomplished with much difficulty, and the joint was easily displaced upon the slightest motion. Patient was kept in plaster for twenty-two months, with a final result as follows: Shortening one-fourth of an inch, slight eversion of the foot, and joint in an anatomical position.

Case XIII. Girl, aged seven years, dislocation of the right hip, shortening three-fourths of an inch. Reduction was easily accomplished, and the limb placed in plaster, where it was kept for seventeen months. Final result was good: Normal gait, joint in anatomical position, and slight eversion of the foot.

Case XIV. Girl, aged twelve years, bilateral dislocation. Preliminary traction was made for ten days. Reduction was accomplished with difficulty in the right hip, but the best result that could be obtained in the left was an anterior position. The limbs were fixed in plaster for twenty months, with a final result as follows: Normal joint on the right side, and an anterior position on the left. There was shortening of one-half inch in the left limb, which caused a slight limp. The lordosis, which was extreme before the operation, entirely disappeared.

Case XV. Girl, aged eighteen months, dislocation of the left hip, shortening less than one-half inch. Reduction was easily accomplished, and the first spica was removed at the end of the fourth month. The joint was so firmly fixed that it did not seem necessary to apply another. This proved to be a fact, with a final result of a perfectly normal condition. Subsequent examination two years later showed joint in position with both limbs of the same length.

Case XVI. Boy, twelve years of age, dislocation of the right hip, shortening one and one-half inches. An attempt was made to reduce the hip without any preliminary traction, as the child could not remain in this vicinity for any length of time. It was impossible to make a reduction by manipulation, and the cutting operation was refused. The limb was placed in the abducted position and held by a spica with the hope that an anterior displacement would be the final result. He passed from observation, however, and his present condition is unknown through examination, but a recent letter from his parents, which states that his gait is much improved, leads one to believe that the expected result was obtained.

Case XVII. Girl, four years of age, dislocation of the right hip, shortening one-half inch. The acetabulum was well formed and reduction was easily made. Spicas were worn for thirteen months with the following result: Limb normal in length, joint in anatomical position, and gait free from limp.

Case XVIII. Boy, seven years of age, dislocation of the right hip, shortening one inch. The head of the bone was deformed and the neck twisted. Reduction was accomplished without much difficulty. The patient remained in plaster twenty months with the following result: Joint in anatomical position, slight shortening with corresponding limp, and

marked eversion of the foot. An osteotomy was advised to correct the eversion, but was refused.

Case XIX. Girl, two and one-half years of age, dislocation of the left hip, shortening one-half inch. Reduction was easily made, but it was with difficulty maintained. At the first change of plaster it was found that the head had slipped from the acetabulum, and another reduction was made. The patient was kept in plaster for fifteen months, with a final result as follows: Limb the same length as its fellow, joint in normal position, and gait showed no limp.

Case XX. Girl, eight years of age, dislocation of the right hip, shortening one and one-half inches, head of the bone much deformed. Reduction was very difficult, and the stability of the joint not good. At the first change of plaster the head of the bone was found in an anterior position, but it was not considered best to attempt another replacement; so the plaster spicas were continued with the following result: One-half inch shortening, slight limp, and head in the anterior position.

Case XXI. Boy, aged twelve years, dislocation of the right hip, shortening one and three-fourths inches. Preliminary traction could not be obtained in this case; so the reduction was attempted without it, and accomplished with considerable difficulty. There was much bruising of the tissues, and marked discoloration followed the operation. Sloughing did not follow, however, but the joint dislocated again, and another attempt to better the condition was not allowed.

Case XXII. Girl, aged three years, dislocation of the right hip, shortening three-fourths of an inch. Reduction was easily accomplished, but the acetabulum was so shallow that the joint was very insecure. Spicas were worn for fifteen months with the following result: Limbs of equal length, no limp, and joint in the correct position.

Case XXIII. Girl, nine years of age, dislocation of the right hip, shortening one and one-fourth inches. Preliminary traction was used for nine days in this case. Reduction was accomplished with much difficulty, but the joint was exceptionally stable. Spicas were worn for eight months with the following result: Slight shortening of the limb, anatomical position of the joint, and slight limp.

Case XXIV. Girl, aged twenty months, dislocation of the left hip, shortening one-half inch. Reduction was easily made. A spica was worn for four months, and, as the *x*-ray showed the head of the bone well situated, the plaster was discontinued. Massage and passive motion were commenced immediately. An examination one year later showed the limbs of equal length, joint in position, no limp.

Case XXV. Girl, thirteen years of age, dislocation of the right hip, shortening one and one-half inches. Preliminary traction was used in this case for two weeks. Reduction was accomplished with much difficulty, but the joint was very secure. Plaster was worn for eighteen months, with a final result as follows: Joint in correct position, one-third inch shortening, and slight limp.

Case XXVI. Boy, four and one-half years of age, dislocation of the right hip, shortening three-fourths of an inch. Reduction was easily accomplished, but as neither the acetabulum nor the head of the bone were well formed it was very difficult to hold the joint in normal position while plaster was applied. Spicas were worn for twenty months, and the final result was as follows: One-third inch shortening, slight limp, and joint in the correct position.

Case XXVII. Girl, aged ten years, dislocation of the right hip, shortening one and three-fourths inches. Reduction was accomplished with extreme difficulty, and the head of the bone slipped from the acetabulum with the slightest movement toward adduction. At the first change of the plaster it was found that the head was anteriorly displaced. It was not considered advisable to attempt to make another replacement. Subsequent examination showed the following result: One-half inch shortening, slight limp, and joint dislocated anteriorly.

Case XXVIII. Girl, aged six years, dislocation of the left hip, shortening one inch. The *x*-ray showed the acetabulum and the head of the bone to be in nearly normal condition. Reduction was made with great difficulty, but the joint was very stable. Plaster was worn for eighteen months, with a final result as follows: One-fourth inch shortening joint in correct position, normal gait.

Case XXIX. Boy, nine years of age, dislocation of the left hip, shortening one and one-fourth inches. Reduction was accomplished after several attempts and the joint was very stable. Spicas were worn for eighteen months with the following result: Shortening one-third inch, joint in correct position, and slight limp.

Case XXX. Boy, nine months of age, inferior dislocation of the left hip, lengthening one inch. Abduction of fifteen degrees was present and an *x*-ray examination showed the head of the femur in the obturator foramen. A reduction was made, and the head of the bone seemed to be so firmly held in position that a spica was considered unnecessary. The patient returned in a few weeks, and it was found that the dislocation had returned. Another reduction was made and a plaster spica applied, which was worn for six weeks. An examination five months later showed the head in a normal position.

Case XXXI. Girl, two years of age, dislocation of the left hip, shortening one-third inch. Reduction was easily accomplished and the limb placed in plaster. The acetabulum was not well formed in this case, and doubt was expressed at the time of the operation as to the outcome. Subsequent examinations, however, showed the parts in normal relation.

Although the number of these cases is small and definite conclusions cannot be drawn, there are some problems in the operation which have been demonstrated to the satisfaction of those who were engaged in the work.

The only case in which there was even an approach to an accident was No. XXI., and in this later observation showed that the operator was too hasty in removing the spica, thereby allowing the dislocation to occur again.

At what age it is best to attempt reduction is a matter of dispute. The results obtained seem to indicate that it is wise to operate while the patient is young, and that, although a good result may be accomplished after the child is well developed, still greater improvement might have been secured had the child been seen at an earlier age. It seems pretty safe to state that development in a dislocated joint is much retarded, and that after reduction is made the whole limb grows in a normal manner.

Undoubtedly, preliminary traction lessens the amount of force necessary at the time of reduction, and should be employed in all older patients. In the cases reported above, the extreme sensitiveness which has been so often mentioned was not seen. Almost without exception, every patient could be easily handled without pain on the third day after operation; many of them moved about freely at a very early period, and in not one was there any pain after the final removal of the plaster spica.

There is one point in the application of the plaster which seems to be of importance, viz., the necessity of making firm pressure just behind the trochanter major, while the plaster can be easily moulded, as it prevents the head of the bone from slipping backward into its former position. The danger of a recurrence of the dislocation through rotation of the thigh bone can be removed by extending the spica below the knee.

The operator should not be in too much haste in trying to accomplish a reduction, as nothing is gained thereby, while, on the other hand, ill-directed force may be productive of serious results. There has been some severe criticism of the operation on account of the use of so much force; the procedure has been termed brutal and unscientific, and in lieu of it the open operation has been advised. It is hardly necessary to state that in such a serious deformity as congenital dislocation of the hip any method of operation which holds forth the hope of such a brilliant result in a large percentage of cases, as this does, *i.e.* a perfectly normal condition, is not to be discredited too readily, and a method substituted which, at its best, offers only a partial relief.

The use of skiagrams has been found to be misleading, and often a case which seemed to present most favorable features has resulted in failure, while others which looked difficult were not so.

Paralysis has never followed any of the above operations, and it is a complication which has never been seen by me.

Summary of Results.—If the two bilateral dislocations are considered as four unilateral, the results may be summed up as follows: Whole number of hips operated upon, 33; 22, or 66 per cent. normal; nine, or 27 per cent., anterior position; two, or 6 per cent., complete failures.

It is to be noted in analyzing this work that the most of the anterior dislocations and failures occurred in the cases operated upon in the earlier part of the work. The better results obtained in the later cases were probably due to a better understanding of the necessary steps of the operation.

SOURCES OF ERROR IN GASTRIC DIAGNOSIS.*

By CHARLES SUMNER FISCHER, Ph.D., M.D.,

NEW YORK.

Probably no department of Medicine requires more careful observation for diagnostic purposes than does the study of abdominal diseases. In the present obscurity surrounding many questions involved, it very often happens that apparently unimportant details, taken into consideration sufficiently, will clear a situation left in doubt by the simple consideration of classic signs and symptoms. It so happens that the diagnosis of some abdominal conditions has reached a stage of such uncertainty that the intelligent examiner is often loathe to accept as positive the results of chemical analysis and physical examination heretofore judged competent to determine fixed pathological states, and is forced to yield to the dictum of the surgeons that the only method to decide anything abdominal, is to have "a look in."

The reason for this dilemma must be apparent to those who have had occasion to make use of the accepted theories and practices of the past. While in the main some of these will remain standard, how many of us have had our sensibilities shocked and pride shattered by accepting too confidently certain supposedly pathognomonic signs in order to render imperative decisions according to the fixed rules of evidence of experimental law. How often has it happened that some minor and apparently unimportant detail, properly observed and estimated, might have saved the situation even though it seemed to contradict all signs of graver import.

That any fixed standard of symptomatology for abdominal conditions should prove faulty in a good proportion of cases, is not surprising when we consider our present knowledge of the subject. We may have carcinoma of the stomach, even in advanced stages, with any degree of acidity. Even the loss of weight can be deceiving in this same disease. We can have ulcers with hyperchlorhydria or achylia. We encounter numberless catarrhs with the same variation of analytical findings. A perfect history of hyperchlorhydria often accompanies absolute achylia. Physiologically and anatomically normal stomachs at times give rise to the most pronounced dyspeptic symptoms, whereas it very often happens that the pronounced abnormal conditions of the same organ produce no symptoms whatever. How often do remote abdominal abnormalities cause distress in perfectly normal stomachs? Vice versa, how often do pathological conditions in the stomach produce deceptive symptoms in other regions?

To a certain extent abdominal surgery has come to the relief of the situation with its exploratory methods. It is, however, a difficult matter to convince the laity of the harmelssness of this procedure, and it can hardly become popular. Even from a professional standpoint, it often fails in its object, and we are no wiser after than before operation. I once had the temerity to ask a well-known surgeon during such an operation, as to the possibility of an existing ulcer. My presumption was met with some sarcasm, which, with other experiences at the operating table, served to convince me that the ordinary abdominal incision and rubber gloved finger do not always enlighten and often reveal only a suspicious nodule or induration with which information we must be satisfied.

One word here in regard to the actual relief measures of surgery. I refer to gastroenterostomy and allied operations. They are a great help in many cases, provided the results obtained are permanent. This, unfortunately, is not always the case. That relief should follow directly after such an operation is natural, for conditions are changed and the stomach for the time being at least, is, to a certain extent, eliminated from the digestive tract. Excessive acidity diminishes as food stasis is improved. Little by little, however, the organ accommodates itself to the new conditions and resumes its functions with the result that old symptoms begin to reappear, due, in all probability to the original abnormalities of secretion. Much has been written about the influence of these operations upon the gastric secretions. Subacidity and hyperacidity should return to normal. That this may result for a few months after operation is apparent from the reasons given, but that such a result must necessarily be permanent, is a fallacy.

In 1900 I published some observations bearing upon this subject. In a series of cases in which it was possible to make systematic examinations over a period of four to six years after operation, it was demonstrated that the secretions were not materially influenced after the lapse of a certain interval, notwithstanding that a certain relief had been accomplished. This applies as well to purely medical

*Read before the New York Academy of Medicine, Section on Medicine, May 22, 1907.

cases. We are too prone to believe that because symptoms have been relieved that the actual secretory conditions causing them have disappeared under treatment. On the contrary, it will often be found that these remain the same for years and the relief afforded will continue just so long as general nutrition remains good and an impressionable nervous system is held in check, both generally and locally.

It is a serious business even partially to eliminate from the digestive tract such a protective organ as the stomach. The importance of the selective motor function of the pylorus and the delicate and intricate cooperation of all alimentary secretions for the purpose of complete digestion of all classes of food stuffs, should warn us against thoughtless and indiscriminate operative interference. Aside from immediate surgical complications, such as jejunal ulcer, adhesions, vicious pyloric circles or fictitious hyperperistalsis, due to pyloric elimination, there exists one which is not usually considered, especially by the surgeons. I refer to the difficulty of subsequent medical treatment in those cases where gastroenterostomy has not afforded the expected relief. In such cases the internist has not only lost all moral support, but his usual mechanical and dietetic measures are rendered ineffective by the artificial conditions created by operation.

It is depressing to admit, on the other hand, that after twenty years of research we possess no positive means to determine certain crucial questions in diagnosis without exploratory measures. We may suspect early malignant conditions, but we cannot diagnose them in the stomach. Were the difficulties limited to the early stages alone, one's natural pride might still be saved. Unfortunately, however, this is not the case. Owing to the delicate arrangements of digestion whereby delinquencies of one part of the tract are counteracted by the increased activity of the other, abnormal growths are often well advanced in their development before their presence becomes known, or even suspected. The usual classic signs and symptoms and the most approved diagnostic methods of the books, will fail use in a goodly number of cases. Let us look at a few of the common signs and symptoms.

It is natural to suppose that the first thing to suffer in carcinoma of the stomach would be the general nutrition as revealed in a loss of body weight. Nothing can be more deceptive. The fundus of the organ may be well involved without affecting nutrition, provided the pylorus remains patent. On the other hand, pyloric malignant conditions may develop so rapidly that death takes place from mechanical causes before sufficient time has elapsed for general malnutrition to become marked. Any rapid loss of flesh in the early stages of a suspected case, can have practical significance, in that it is presumptive evidence that the process is so localized as to interfere with gastric and intestinal cooperation, and thus may still be amenable to operation with some hope of relief.

The maintenance of body weight naturally implies a sufficient appetite to stimulate the nutritive intake. This natural craving for food at regular intervals, while generally impaired in malignant conditions of the stomach, may be perfectly normal and at times even increased until the disease is well advanced. It appears that in the early stages, in some cases, where no dyspeptic symptoms are prominent, the appetite may be stimulated by the increased tissue development of abnormal cell proliferation. Of more diagnostic importance than mere loss of appetite, are certain peculiarities of the same. I refer to sudden disinclination to take a particular variety of food notwithstanding it causes no distress. This phenomenon is, apparently, a mental one, and may appear very early in the disease. It is especially true of the proteids. When it occurs in a suspected case, with no neurotic tendency, it is worthy of note, and should act as a warning.

It is generally conceded that loss of strength is of greater diagnostic importance than loss of weight. Both of these signs require some time for their development, and thus are deprived of their value for early diagnosis. It sometimes happens, however, that very early in malignant disease of the stomach, patients give evidence of loss of strength in a subtle way. It is not general weakness, but rather a disinclination to pursue activities which previously had been a pleasure. It is a psychological state rather than a physical one, and is entirely out of proportion to any actual suffering. If this occurs in individuals with normal nervous systems and surroundings, it should be taken into consideration. I refer to a loss of ambition on the part of an individual of middle life, suffering from slight dyspeptic symptoms, not calculated to produce any marked nervous disturbance. It appears to be a subtle psychological influence upon the mental condition of which he has no definite consciousness. In these days of general neurosis, it is evident that such evidence may be easily overlooked or discarded. At the same time, when it occurs under the circumstances mentioned, it may serve as a hint as to the actual state of affairs. It can be of value at a time when all physical and chemical methods are premature, so far as definite results are concerned.

Some such indefinite phenomena occur in almost every case, but are usually discarded because we do not wish to appear visionary. The more we have to deal, however, with abdominal disease, the more we must recognize that each case is analytical and individual and that any hint or detail may not be disregarded. In no class of cases are actual pathological conditions and signs and symptoms so out of proportion and badly related. Under such conditions, apparently unimportant details, properly observed and estimated, will often save the situation.

Most sources of error in gastric diagnosis involve conditions at the pyolrus. The primary question in all cases of obstruction, is that of malignancy, and it very often happens that after all chemical and physical data have been collected in a given case, even in advanced stages, we are obliged to rely upon minor facts of the history in order to reach some sort of a conclusion. The presence or absence of a tumor mass is often a matter of such doubt that little reliance can be placed upon any individual examination. Too much depends upon the tactile erudition and imagination of each examiner,—both very uncertain quantities. Granted, however, that these faculties are fully trained and developed, we have still to reckon with the pylorus itself. Unless this sphincter is absolutely destroyed by new tissue infiltration, it may assume a changeable consistency dependent upon the vigor of manipulation, length and number of examinations, and local irritability. What one examiner may feel as a suspicious hardening may have disappeared by the time of the next manipulation. Hence, the first examiner always has the advantage, and no two examinations should be made in immediate succession. This uncertainty will continue until infiltration is so complete as to render contractions impossible, by which time other symptoms will probably have decided the question. If the pyloric contractions are vigorous and continue into the late

stages of the disease, it is evidence that the sphincter has not been completely involved, for complete infiltration would tend to suppress muscular contraction entirely, whereas a small and hard nodule, acting as a foreign body, would serve to stimulate contractions. Hence, complete infiltrations may be more difficult to detect than incomplete ones, especially if the same be soft in their nature. They have destroyed the power of contraction. At the same time, their own consistency does not betray them.

In this connection, we must consider tenderness to pressure in this region. As a sign of malignancy it is of doubtful value, for the pylorus may be more or less sensitive under normal conditions. If the examination is made under or induces contraction of the sphincter, there is certain to be more or less pain on pressure. Continued pressure may result in relaxation of the muscle and disappearance of the tenderness. In the one case the pylorus may be felt. Two examiners, thus, may secure entirely different impressions according to the actual state of the structure at the moment. Hence, tenderness to be of value must be not only constant, but localized.

Another peculiarity of pyloric tumors is a tendency to induce muscular irritability of the esophageal structures, resulting in spasmodic resistance to the passage of the stomach tube. If, in a given suspicious case, in the earliest stages, this phenomenon occurs, it is worthy of consideration, and has been referred to by earlier writers. It is of value only in cases where neurotic tendencies can be excluded. It is a reflex pure and simple, but under certain conditions may be a hint of value.

Visionary as some of these suggestions may seem, we are obliged to consider them on account of the failure, in many instances, of the hard-and-fast rules of diagnosis of the books. It not infrequently happens that an operator reveals conditions calculated to produce and which have failed to produce the classic signs and symptoms. Of such conditions there are four which occur to me at the present time. These are: small, hard, nodular growths at the pylorus, tubular infiltration of the pylorus, spasmodic reflex contraction, and duodenal obstructions just beyond the pylorus.

We have been taught to believe that in cases of pyloric stenosis, with resulting dilatation, the differential diagnosis between malignancy and benignancy depends largely upon the duration of the disease, all other things being equal. Slow development should signify a benign condition. It sometimes happens, however, that instead of a simple connective tissue contraction we find a small nodule, very hard in consistency, causing a partial obstruction, but sufficient to give all the characteristic symptoms of retention without previous history of ulcer. The duration and development, in these cases, may be very long and hyperchlorhydria, due to overstimulation of retention, may be marked. The dilatation is usually very marked, but benign obstructions of long duration produce this result as a rule. Such a nodule may grow very slowly, and does not produce emaciation necessarily, for its bulk is not great, and there is no absolute obstruction. In such cases, it is almost impossible to avoid error at times.

Another condition which is apt to be confusing is one in which infiltration has resolved the pylorus into a rigid tube with a fairly patent lumen. In these cases there need be no great food retention and no dilatation whatever. On the contrary, the stomach may not only be quite empty, but almost constantly contains bile. This, in itself, can be misleading, for the constant presence of bile is supposed to contraindicate stenosis. All the vomited material will contain bile and be exceedingly bitter to the taste. As the history may be one of some duration and the loss of flesh slight on account of preserved intestinal digestion, the diagnosis may be obscured or rendered impossible. Some suspicion of the actual condition may be aroused by physical examination. In such cases it is sometimes difficult to determine the size and position of the stomach by filling with water or by insufflation, as both air and water escape readily into the intestine. A normal pylorus will close instinctively upon the sudden introduction of either of these elements in any considerable quantity. In the normal state, the stethoscope placed over the pylorus discloses interrupted gurgling or bubbling, whereas in the condition described the sounds are those of constant rushing of air or fluid through the opening. The same phenomena can be noted in pyloric insufficiency, but this condition is so rare, and the general neurosis producing it so pronounced, that no difficulty should arise on this score.

Under ordinary circumstances, the differential diagnosis between gallstone disease and benign pyloric stenosis should not present much difficulty. It sometimes happens, however, that a reflex spasm of the pylorus of such intensity and duration may be induced as to cause doubt as to the proper diagnosis. Test foods can be found in the stomach twenty-four to forty-eight hours after their introduction, and the vomited material may be large. This condition may persist for days after the actual gallstone colic has disappeared. Examined during this period, the physical and chemical findings would indicate pyloric stenosis, and as both benign pyloric conditions and gallstones are of long duration, the differential diagnosis may be difficult. In such doubtful cases it is necessary to persist in the examination of the stomach. If it be found that the food retention and hyperchlorhydria gradually disappear, the diagnosis of gallstones is the most probable one. No dilatation results, in these cases, as the organ returns to normal between the attacks. In this respect, they differ from ordinary recurrent pyloric spasms, due to persistent hyperchlorhydria, and which may eventually result in dilatation.

In certain cases the spasmodic contraction may exist at a point just beyond the common duct. This can occur in gallstone disease or as a reflex from other organs in the immediate vicinity. According to recent investigations there exists at this point of the duodenum a certain thickening of the circular muscular fibers of the intestine which, under reflex stimulation, may cause retention. In such cases the symptoms are those of pyloric obstruction, whereas, in reality, the pylorus may be entirely relaxed. This relaxation may be permanent or temporary. In either contingency the distinctive feature of these cases are absence of gastric dilatation, absence of hyperchlorhydria, and the constant presence of bile in the retained contents. It is difficult to outline the stomach on account of the constant escape of fluid or air into the duodenum. If, however, the history is one of long duration, with symptoms resembling pyloric spasm and copious bilious vomiting without hyperchlorhydria and dilatation or marked emaciation, the possibility of the suspected cause may be entertained. At best, only the closest analysis of details can lead to any sort of a conclusion in such cases. In instances where the attacks are not frequent, the stomach returns to normal between the attacks. This feature is im-

portant in that in connection with absence of general emaciation and dyspeptic symptoms, it differentiates the condition from one of duodenal ulcer.

Among remoter influences which may affect the pylorus and direct attention to it as the seat of some organic lesion, are sudden atmospheric changes, sudden mental irritation, and hysteria.

The first condition occurs in individuals, usually males, of middle life, robust physique, and normal nerve tone. As a rule, there is a gouty diathesis. These patients admit no indiscretions in diet, but attribute their attacks to sudden atmospheric changes. The distinctive feature of these cases consists of sudden seizures of acute pyloric spasm leading to food retention, with all the accompanying symptoms. The gastric acidity is usually high, but there is no evidence of food decomposition to a marked extent. There may or may not be considerable mucus present. These attacks differ from acute gastritis in that they occur with great suddenness and the absence of diffuse tenderness over the fundus. The pain is spasmodic and corresponds to the rhythmical contraction of the pylorus, which may be felt at times as a hard elongated body. There is no dilatation, and the organ returns to normal within a day. If the attacks occur with any frequency, gallstones are usually suspected, and it is only by thorough physical examination during an attack that the real cause may be revealed. The history of previous attacks must be carefully considered.

Emotional disturbances will occasionally cause such marked gastric symptoms as to mislead. They are of interest from a psychological standpoint. They may be controllable or uncontrollable, that is, within or without the individual volition. The first class is represented by conditions of what is ordinarily called "temper." The second class is identified with hysteria. It might be called post-prandial hysteria. Whichever the cause, the result is the same, namely, sudden pyloric spasms, with the usual result.

The first condition can be dismissed with few words. It occurs in young individuals whose mental disposition is such that upon slight provocation they "fly into a rage." This, in turn, induces pyloric spasm and food retention. If this combination occurs frequently, it may lead to some doubt as to the actual gastric condition and cause parental alarm. Examination of the stomach reveals nothing abnormal between the attacks. The difficulty, in these cases, lies not so much in diagnosis as in treatment. They submit to examination unwillingly, and their whole disposition is antagonistic. It almost seems that they do not desire relief, and the summoned physician becomes their enemy. It appears to be a morbid satisfaction to them to inflict their suffering upon others, and treatment is well-nigh useless. The latter resolves itself into a question of moral suasion, family influence, or parental firmness.

In post-prandial hysteria we have an emotional condition reflecting upon the pylorus, which is somewhat out of the ordinary. In these cases, instead of the usual exaggerated post-prandial lethargy and torpor of the ordinary neurasthenics, we have general mental excitation and alarm and physical restlessness. There may be palpitation, poststernal oppression, and other nervous symptoms, but these are not distinctive. The principal feature is the hysterical seizure and mental attitude of the individual. The attack occurs immediately the meal is finished, that is, before any digestive disturbance is possible. It occurs further only after a certain meal and at a certain time of day. It affects both gastric sphincters so that the stomach becomes a closed sac. When the cardiac orifice relaxes, eructations and vomiting occur. This may or may not bring relief. Gastric analysis and physical examination of the stomach give normal findings. The local discomfort of these patients is due to tonic contraction of the sphincters. If this is most pronounced in the pyloric region, it may lead to doubt as to actual condition of this orifice, especially if the attacks occur with more or less regularity, and exploration with the gastric tube reveals the cardiac end of the stomach to be normal. The guiding feature in these cases should be the peculiar mental condition following immediately after certain meals at a given period of the day.

Two conditions in the immediate vicinity of the pylorus may cause doubt as to its normality. One of these is distention of the hepatic flexure of the colon. As a result of mechanical causes due to position, antiperistalsis in the ascending colon, etc., this flexure is more or less distended normally. Should this become excessive for any reason, it may cause discomfort amounting at times to painful spasms either in the regions of the appendix or pylorus. In nervous individuals attention is at once directed to the appendix on account of the prevailing fear of this affliction. In the physical examination of such a case, the high distention may direct attention to the pylorus, and at times it is difficult to determine the size of stomach by ordinary methods, especially if there be considerable distention of the transverse colon at the same time. If, as it sometimes happens, hyperchlorhydria and atony of the stomach are also present, the situation becomes still more complicated. As these cases are usually very insidious in their onset and of long duration, it is advisable before making a physical exploration of the stomach to thoroughly relieve the colon by high oil rectal injection, repeated over a period of several days, if necessary.

It seems hardly necessary to refer to prolapsed right kidney as the cause of pyloric spasm and gastric symptoms, and yet, in its early stages this cause can easily be overlooked. If both kidney and stomach have prolapsed to a pronounced extent, symptoms of spasmodic retention are not so likely. The organs accommodate themselves to the new conditions. The greatest tension of a prolapsing kidney occurs in the very early stages, before the ligaments have become thoroughly relaxed. At this time the tension is more or less constant, and is not relieved by varying bodily position. Reflex influence upon other abdominal organs at this time is greatest, and as the movable kidney is easily overlooked, false conceptions may result. If the reflex is directed to the pylorus, in such a case, repeated attacks of pyloric spasm may result and, as the primary condition is a slow one, the constant recurrence of these attacks will lead to permanent changes in the stomach. In the course of time, as the ligaments of both stomach and kidney become more and more relaxed, the acute attacks cease of their own accord, and give place to the typical train of symptoms of gastroptosis. Ordinary treatment in the early stages is useless. Operation upon such a kidney will at once relieve at this time. Both patients and surgeons, however, take unkindly to this radical procedure at this early stage, and these unfortunates are doomed to suffer until Nature comes to the relief of their acute symptoms through absolute relaxation of the suspending structures, thus insuring at the same time some hope of help from a supporting bandage.

To what extent a reflex from a slightly loose

right kidney may deceive, is illustrated by two cases which have come under my observation. In both cases there were marked evidences of pyloric spasm, with food retention and hyperchlorhydria. In both cases masses the size of a goose egg were discovered located midway between umbilicus and ensiform cartilage. These were tender to pressure. These conditions had existed for months. There was no gastric dilatation or displacement. The abdominal walls were tense, so that no kidney displacement could be discovered upon ordinary physical examination. There was considerable loss of weight and strength, due to repeated attacks and enforced curtailment of nutrition. Both cases were those of very young neurotic women. Gastric ulcer was suspected, but no cardinal signs of this affection were present. The tumor masses were puzzling and permanent. Exploratory operations were decided upon, and the young women placed under ether. Under the anesthetic the epigastric tumors disappeared. Nothing could be felt at the pylorus, but careful examination revealed the right kidney, in each case, to be slightly loose. The real nature of these cases was suspected, and the kidneys were placed in position by the usual operation. Both cases made good recoveries, and have been free from symptoms ever since. In these cases we had primary nephroptosis and secondary reflex pyloric spasm. As the latter became more constant, the abdominal muscles contracted as a relief measure, and this finally resulted in phantom tumors.

It would hardly seem possible at this late day to evince much interest in two very common conditions of the body of the stomach, such as atony and catarrh. They are easily diagnosed, and have been thoroughly investigated. Being easily diagnosed, however, may lead to their being too frequently diagnosed, and in this lies the danger.

In the case of atony, we have been in the habit of relying upon Leube's seven-hour fasting test, and according to this method it has developed that fully fifty per cent. of all chronic gastric conditions contain the element of atony. Reliable as this test is there still lurks in it some possibilities for error. These consist chiefly in errors of judgment as to the quantity of residual food which would warrant a diagnosis, and the frequency of its occurrence. As to the quantiy of residual food present, I have found that it is common practice to pronounce certain cases atonic when the lavage fluid, seven hours after a Leube test, contains only a few flocculi or is simply turbid. This procedure may constitute error, for small quantities of food may easily adhere to the gastric mucosa, even where there exists a condition of hypermotility. It is almost constant in cases where there is a catarrhal condition. Now catarrh and atony are not only not usually associated but, on the contrary, catarrhal stomachs empty themselves as a rule most readily. It is this feature of a catarrh of stomach which makes it possible for this condition to exist for years without producing distressing symptoms, and the maintenance of good and often excessive appetite. Lavage, however, will almost always reveal a small suspended quantity of food in these cases. Hence, it is unreliable to depend entirely upon this procedure. If a stomach is really atonic, it will contain a decided quantity of food at the end of the time limit. This can be extracted by ordinary suction without lavage. It is important to observe the proper time-limit for this examination, for it is a popular fallacy that a normal stomach must empty itself completely in the short interval between meals as ordinarily taken at the present day. A hearty eater may have food in his stomach at all hours of the day, and still be apparently normal.

Quite as important as the presence of food after the Leube test, is the constancy of its presence and the nature of the food administered. Just as in the determination of the secreting capability of the stomach, it is necessary to analyze the gastric contents after various meals, under varying conditions, so in determining the presence of atony, repeated examinations are obligatory. The occasional presence of a small quantity of food is no proper evidence upon which to base a diagnosis. A true atonic stomach always contains food in a certain state of decomposition at the end of seven hours. The occasional presence of food may only indicate a temporary weakness or rather sluggishness on the part of the muscular structures, for in these days of general neurasthenia the activity of both voluntary and involuntary muscles depends largely upon the state of the nervous system at the time. Examine a neurasthenic on his days of general mental and physical depression, and you are more than apt to find residual food in the stomach at a time when it should be empty normally. This may be purely temporary, and does not constitute atony as we understand it. More than likely this same stomach will empty itself too rapidly during periods of general nervous excitation. In doubtful cases it is, therefore, necessary to make repeated tests. It is superfluous to caution against accepting as evidence of atony the presence of vegetable fibers, seeds, etc., These substances will remain in perfctly normal stomachs hours after all digestible foods have disappeared. If the test meal be given as breakfast in the morning, for instance, and include an orange, the pulp of that fruit will be found long after all the other substances have passed on. Substances absolutely indigestible for the whole alimentary tract, if present in any bulky form, are apt to be retarded by the pylorus in its capacity of selection. In other words, a normal test-meal should contain only foods which have the right to pass out of the stomach within a certain prescribed time.

What constitutes a chronic catarrh of the stomach? Formerly everything connected with the stomach was catarrh. Experience has taught us to limit the diagnosis, however. It is no such simple matter to properly estimate this condition. The mere presence of a small quantity of mucus is not sufficient to confirm the diagnosis. This may normally be present in any stomach. Certain other factors must be taken into consideration. If mucus is found in a stomach, these would be principally the age of the individual, the kind of test administered, and the effect of nervous influences.

The age of the individual is important, because a certain quantity of mucus can always be found in cases of very old or very young persons. This mucus may have no special significance, at least, may not constitute a catarrh, in the strict sense of the term. For the latter there must be a causative basis and corresponding history. In the very young a certain quantity of mucus is rather an expression of cellular activity common to this period of life. It disappears as the years advance. In persons of advanced age, mucus results from the degenerative changes to be expected at this time, and may not be an evidence of disease. In middle life the presence of mucus, in any considerable quantity, must arouse suspicion. Even here, however, there are chances for error, not so much in estimating the mucus itself, but in the methods employed. It frequently happens that a simple test breakfast of tea and roll produces no mucus, whereas, if meat be added to

the test, the gastric contents will appear viscid and stringy, adhering to the sides of tube and vessel in the manner of true mucus. This may be deceptive, for a test meal containing meat, especially if the latter holds much connective tissue, can take on this character as a result of the action of the hydrochloric upon the fibrous elements. In reality, we have nothing but dissolved or swollen connective tissue. Hence, in examining for catarrh, it is better to employ only the simple test. In doubtful cases, a simple chemical test may be employed as follows: five cubic centimeters of filtered gastric contents are thoroughly shaken with five cubic centimeters of a 5 per cent. alcoholic solution of bichloride of mercury and ten drops of Erhlich triacid stain. All mucus and proteids are precipitated. Filter and wash the precipitate on the filter thoroughly with water. If the precipitate is composed of much mucus, it will remain a dark green; if it is composed of acid albumin it will be red or purple. This latter dissolves readily in 25 per cent. acetic acid, whereas the mucus combination is insoluble. This simple procedure is a modification of a similar von Noorden test for mucus in the stools.

An interesting question in connection with gastric mucus secretion is the effect of nervous influences upon the same. The idea seems rather remote; at the same time there apparently exist certain relations between nervous conditions and gastric mucous secretion which cannot be ignored, especially as we have ample example of this relation in other regions. The question of the nervous origin of mucous colitis is not settled, and we know that acute coryzas may result momentarily from nervous influences. I have on various occasions found the stomachs of neurasthenics filled with mucus under the impulse of sudden emotional disturbance, whereas, ordinarily, these same stomachs were free from this substance. Such rapid accumulation leads to nausea and vomiting and, at times, to severe gastric pains. There can be no question of acute gastritis, for evidences of inflammation are entirely absent and the causes are apparent in the nervous origin. Such stomachs may be perfectly normal in the interim, and represent cases of what might be called "acute neurotic mucous gastralgia." The diagnosis of these cases depends upon repeated observations over an extended period of time. A single examination can and must, necessarily, mislead.

My only excuse for offering the apparently unimportant details of this paper is that, in the mad rush for novelty and reputation, it can do no harm to occasionally pause for a survey and correct understanding of what has been accomplished in the past.

PREVENTION AND TREATMENT OF CYSTITIS.*

By PAUL PILCHER, A.M., M.D.,

BROOKLYN, NEW YORK.

SURGEON TO THE GERMAN HOSPITAL; ASSOCIATE-SURGEON TO ST. JOHN'S HOSPITAL; AND CYSTOSCOPIST TO THE JEWISH HOSPITAL.

Etiology.—Cystitis is always due to infection with bacteria. There are many forms of congestion, hyperemia, and edema of portions of the bladder which are not due to infection, and which resemble very closely true cystitis, but at the same time they can not be considered as typical forms of inflammation although they frequently end in cystitis. The ingestion of irritating drugs, exposure to cold, extensive burns of the body, traumatisms, highly acid urine, oxaluria, and retention of urine may cause congestion and hyperemia, but unless bacteria gain entrance and attack the mucous membrane, true cystitis does not develop. These congestions and traumata may be present without symptoms. By the use of the cystoscope, in cases in which extensive hysterectomies have been done, we almost always find congestion of the base of the bladder, and frequently numerous areas of ecchymosis. Where extensive cystocele exists, patients often suffer from pain, retention, and frequency of urination due to hyperemia and edema of the trigonum, and yet no cystitis exists. Such cases are mistaken for cystitis and treated as such without any result.

Gouley tells us that cystitis may be due to "deviations in the quantity or quality of the urine," and "to the stagnation and fermentation of the urine." It is true that the first may be an underlying cause and retention may predispose, but the cystitis does not develop until the bacteria gain entrance, changing the urea to ammonium carbonate which, in turn, irritates the bladder mucous membrane and prepares it for the invasion of the bacteria. The presence of the bacteria alone is insufficient in the normal bladder to cause an inflammatory reaction, and as long as the mucous membrane or the tissues of the bladder wall are uninjured, cystitis is not likely to develop. Wreden (quoted by McWilliams, Medical Record, July 7, 1906) demonstrated that on traumatizing the rectum and injecting colon bacilli into it, the bacteria could be recovered from the urine in the bladder; also that oil and vaseline may be transmitted directly from the rectum into the bladder. Seventy per cent. of the cases of cystitis, according to the consensus of many observers, are due to the colon bacillus. The wonder is that so many cases escape infection.

Almost invariably instrumentation of the bladder causes some slight abrasion; cystoscopic examination after sounding for stone shows numerous abrasions of the mucous membrane; and even the introduction of a soft catheter is damaging to the trigonum.

For the object of our study it is not necessary to review the various predisposing causes of cystitis, most of them are well known; it is important to remember, however, that instrumentation and retention of urine are the two most frequent predisposing factors. Tuberculous inflammation occupies a separate chapter.

Cystitis which follows abdominal section in pelvic operations should be noted. It occurs, according to Taussig, in 60 per cent. of the cases after the radical operation for cancer; it is in direct proportion to the amount of injury to the bladder itself, its blood-supply, or nerve-supply. Retention of urine usually follows the operation, the resistance of the patient is greatly lowered, and many patients have to be catheterized for a prolonged period; the inflammation rarely develops after a few catheterisms, provided the proper aseptic precautions be observed, but after five or six days in the cases where there has been some trauma to the bladder, the inflammation frequently occurs.

Pathology.—Clinically, cystitis may be classified according to location and distribution of the lesion, as: 1. *Localized cystitis,* in which only a limited area of the bladder is involved; generally the trigonum and base of the bladder. 2. *Diffuse cystitis,* involving the entire mucosa of the bladder. 3.

*Read before the Medical Society of the County of Kings, May 21, 1907.

Patchy cystitis, where the areas of inflammation are scattered irregularly over the mucosa.

Etiologically, cystitis may be classified as: 1. *Traumatic cystitis,* due to infection following trauma. 2. *Cystitis* due to *extension* of *infections* from other organs. 3. *Obstructive cystitis,* following stricture of the urethra, hypertrophy of the prostate, cystocele, and paralysis of the bladder. 4. *Neoplastic cystitis* (Casper), due to the pressure of new growths and infection. 5. *Tuberculous cystitis.*

The first classification is the outgrowth of the modern methods of examination. We have found by repeated cystoscopic examinations that in many cases the inflammation is a limited one, and this emphasizes the necessity of a more thorough knowledge of the lesion before treatment is undertaken. In the *localized* and *patchy* cystitis there is frequently more healthy bladder mucosa than there is inflamed mucosa, and Kelly has pointed out that strong solutions, if used in these cases, would injure the healthy membrane.

The second classification is equally important, since it directs our attention to the underlying cause of the disease, which must be removed before recovery is possible.

The most frequent site for the development of acute cystitis is the trigonum and base of the bladder; this region is naturally the first attacked because it is the most dependent portion of the viscus; its mucous membrane is continuous with that lining the urethra and the ureters, and is most frequently injured by catheterism. The rich capillary supply of the trigonum makes the hyperemia more pronounced at this point.

In the cases of cystitis in which there is obstruction to the flow of urine, such as hypertrophy of the prostate and stricture of the urethra, the muscular bands of the bladder hypertrophy and are seen on the inner surface of the bladder as innumerable trabeculæ which by their interlacings form pockets of varying depths, and when this type of bladder becomes infected it constitutes a most intractable form of the disease. At times those trabeculæ dilate and form diverticula or pouches, which increases the difficulty.

As the inflammation advances destruction of tissue may occur, abscesses form, break down, and leave unhealthy ulcers.

Diagnosis.—Many cases come to us with a diagnosis of chronic cystitis having resisted all forms of treatment, with varying periods of improvement but with constant relapses. The reason for the failure in many of these cases is an insufficient knowledge of the predisposing factors. Unless the source of the infection be discovered and removed, local treatment will be unavailing.

The steps necessary to establish a diagnosis of cystitis include (1) the history of the illness; (2) the examination of the patient; (3) the examination of the urine; and (4) an examination of the mucous membrane of the bladder by the aid of the cystoscope.

Hyperemia of the trigonum, as described by Kelly of Baltimore, is a condition which is often mistaken for cystitis. The trigone is deeply congested, a rosy red in color, extending to and often involving the ureteral openings; the mucous membrane is swollen and there is a varying degree of edema which can be easily appreciated by vaginal examination. The symptoms are characteristic; there is frequent desire to empty the bladder, sometimes present both day and night; the patient complains of burning sensations and pressure or bearing down at the neck of the bladder; the passage of urine is accompanied by some pain, but the greatest distress is present after voiding the water, the sense of weight and pressure remaining for some time. When, in addition, the urine is concentrated or highly acid, the suffering is greatly increased, and urgency of micturition may be present every few minutes.

Most of the cases of "irritable bladder," "neuralgia of the bladder," etc., come under this head.

The diagnosis is easily cleared up by direct inspection of the bladder. The trigonum is intensely congested, sensitive, and in some cases the swelling of the mucous membrane is very marked.

The treatment must be directed to the cause, if possible. Rest, diluents, flaxseed tea, citrate of potash, etc., are indicated. It is necessary to emphasize the importance of an exact diagnosis before undertaking the treatment of any case.

Prevention.—It has already been stated that cystitis is apt to develop in those cases in which there is marked obstruction to the efflux of the urine. The prevention here depends on our ability to remove the cause; strictures should be dilated, and the hypertrophied prostate removed; acute retention of the urine from whatever cause must be guarded against; calculi and tumors of the bladder must receive their appropriate treatment. Gonorrhea is a prolific source of infection and great care should always be exercised in giving urethral injections for its cure, particularly in the early stages.

In employing catheterism the most careful asepsis should be used in the preparation of the patient, instruments, and the operator's hands. In introducing the catheter great care must be taken to prevent injury of the urethra and of the base of the bladder. In removing urine from the bladder, the urine should be allowed to escape slowly in order to avoid the violent embrace of the tip of the catheter by the bladder wall. Following catheterism, it is well to instill a few drops of a 1-in-1,000 solution of silver nitrate on the trigonum and throughout the urethra, and to administer by mouth one of the milder urinary antiseptics.

The prevention of postoperative cystitis is a most important question in our hospitals; this is especially true of the gynecological cases where the bladder has been subjected to any traumatism. Our practice during the past two years in these cases has been as follows: During the operation care is taken not to inflict traumatism on the bladder; after the operation, when it is necessary to catheterize a patient, a No. 16 French catheter is introduced into the bladder and the urine is allowed to escape slowly; 4 or 5 ounces of boric acid are then injected into the bladder and allowed to escape. If it does not distress the patient too much, a second injection of 8 ounces of boric acid solution is made in order to remove, if possible, any bacteria or foreign bodies which may have been forced into the bladder by the introduction of the catheter. Personally, I find it better to use a large syringe for the injection, partially on account of the ease with which it may be sterilized, and also because the force of the injection may be entirely controlled by the hand of the one giving the injection; the ordinary douche-bag may be used, but it is not so safe. At the same time, doses of urotropin are given by the mouth.

In cases of repair of the cervix and perineum, the patient is allowed to urinate immediately after the operation, if possible; the perineum, if it has been sutured, being protected by a bit of gauze or sterilized rubber tissue. Following out this method,

we have almost eliminated postoperative cystitis from our wards. One case, a man, during his first two weeks in the hospital, was catheterized thirty-nine times by actual count, and this catheterism was continued for two weeks longer without the development of any cystitis. Many cases may be rescued from catheterism if sufficient time and patience are used in inducing the patients to empty the bladder voluntarily; in almost all postpartum cases the women can be induced to urinate if they are raised up in bed and allowed for a few minutes to assume the sitting posture. Many patients who have been operated upon, also, can be postured so that they are able to avoid the catheter. The use of a warm enema, hot moist cloths over the pubis, or the pouring of water from a container into another receptacle, will often aid their efforts.

The dangers of postoperative cystitis can not be too strongly emphasized; we are constantly seeing patients who have been operated upon and who have left the hospital cured, but owing to a lack of precaution in catheterism a persistent cystitis has remained which had never been suspected, or even reported to the attending physician.

Treatment.—In the treatment of all cases, the removal of the underlying cause is of primary importance; we cannot expect to have a permanent recovery from cystitis if the urethra still remains infected, if the kidney is still the site of pyelitis, if the enlarged prostate still obstructs the efflux of the urine. In the acute cases, from whatever cause, bladder irrigation is contraindicated except in the declining stage of a gonorrheal cystitis. Rest in bed, with the hips elevated, will often give considerable relief from the strangury and the constant desire to urinate; by elevating the hips the water which accumulates in the bladder flows away from the trigonum, which is the most congested and acutely sensitive portion of the bladder. Opium and belladonna may be given in suppositories to control the pain. Heat to the perineum and above the pubis, and hot sitz baths, will greatly relieve the tenesmus, and to some extent lessen the congestion of the bladder mucous membrane. Diluent drinks should be freely given; if the urine is highly acid, mixtures containing potassium citrate and hyoscyamus will render the urine less irritating; hot rectal enemata are also indicated. Since the introduction of urotropin (and allied drugs) there has been considerable discussion as to its usefulness; when administered by the mouth, urotropin is broken up into ammonia and formaldehyde gas, which latter is liberated as such in the urine. Dudgeon (*Lancet*, June 20, 1906, page 159) claims that this drug can not be given in large enough doses to have any marked antiseptic effect in the bladder, but the clinical evidence does not substantiate his objections. However, in our enthusiasm over a drug which has helped in some cases, the tendency is often to forget the agents which were formerly used, and which materially aid in the treatment of these cases; infusion of linseed, buchu, and triticum repens are often of value in acute cases. In the subacute stage, the oil of sandalwood, cubebs, and copaiba are most useful, but should not be employed for more than a few days at a time. In many cases, salol in doses of from ½ to 1 dram a day is more effective than urotropin.

In chronic cases, the treatment may be divided into the nonoperative and the operative treatment.

Some patients may be benefited by the use of drugs, rest in bed, and regulation of the diet, but in most cases, regular catheterism, irrigation of the bladder, and the use of some of the silver salts or of iodoform emulsion are called for. In the gonorrheal cases, oil of sandalwood or oil of copaiba, combined with salol, and given in capsules, is of great benefit.

The object of washing out the bladder is primarily to cleanse the mucous membrane, and to remove the bacteria, mucus and other detritus which are present in the bladder and are constantly irritating its mucous surface; in order to accomplish this, warm sterile water is sufficient. It is not always necessary to introduce the catheter in order to irrigate the bladder, but in order to do it thoroughly it is best to use a catheter of large size, or an evacuating silver catheter; as soon as the liquid returns clear, the irrigation may be stopped.

Solutions of silver nitrate (½ of 1 per cent.), argyrol (20 to 50 per cent.), and iodoform emulsion have been found most useful. The method of using these solutions is as follows: After irrigating the bladder until the liquid returns clear, 2 ounces of ½ per cent. solution of silver nitrate is injected into the bladder and the catheter removed; the patient is to retain this solution for twenty minutes, if possible, and then pass it voluntarily. The argyrol and iodoform emulsion are used in smaller amounts, but in the same way. The instillations may be repeated every two or three days.

Direct application is by far the most efficient method of dealing with chronic cystitis. It is not applicable in the male, but can be done in the female with the patient in the knee-chest posture, and through a vesical speculum. The application is made with the mucous membrane in plain sight; for this, stronger solutions of silver nitrate may be used, and where ulcers are present they may be cauterized by the silver stick, or, if preferable, by carbolic acid or the actual cautery.

Surgical Treatment.—Some cases of chronic cystitis resist all of the ordinary methods of treatment; the patients are worn out by their suffering and are willing to subject themselves to any form of treatment that promises relief. In the case of cystocele and prolapse of the uterus, surgical intervention with the correction of these deformities will lay the foundation for the relief of the existing inflammation of the bladder. In cases of contracted bladder with thickened walls and an old chronic cystitis, the establishment of a vesicovaginal fistula will result in recovery after all other methods have failed. In the male, suprapubic cystotomy or perineal section is indicated; when the bladder is opened the mucous membrane is thoroughly cleansed, ulcerated surfaces are treated, and if necessary the whole bladder may be curetted. It is not sufficient simply to drain the bladder, but it must be subjected to daily irrigations and, if necessary, topical treatment. After the course of a few weeks, the cystitis subsides; as a rule, the fistulæ close, but sometimes secondary operations are necessary.

In reviewing the entire subject, the necessity should be emphasized for exact diagnosis and appreciation of the exact pathological condition. In the acute cases, catheterism is contraindicated; in the chronic cases, as a rule, a direct examination of the bladder mucous membrane is most important; in those cases which resist all treatment, the existence of tuberculous cystitis must be suspected, and to determine this the safest method is the injection of 10 c.c. of the urine into a guinea-pig.

Castor Oil.—Cracked ice held in the mouth before taking castor oil chills the tongue and prevents any disagreeable after-taste.—*Nurses' Journal of Pacific Coast.*

MEDICAL RECORD.

A Weekly Journal of Medicine and Surgery.

THOMAS L. STEDMAN, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 51 FIFTH AVENUE.

New York, May 23, 1908.

THE INCREASE OF THE ARMY MEDICAL DEPARTMENT.

THE nation is to be congratulated upon the passage of the law increasing the efficiency of the Army Medical Department—the first step in the direction of preventing the repetition of the camp scandals of the Spanish War. The bill as originally drawn was quite modest, but it was side-tracked in favor of the Ordnance Department, and again the Artillery, and then, instead of being increased still further to provide for these two increases in the army, it was cut down below the original. Nevertheless, half a loaf is better than none, and the readjustment of grades will make promotion reasonable in the future. The medical officer becomes a captain in three years instead of five as formerly, and those who enter the army in the next few years will attain the rank of major in a comparatively short time, as they have only one hundred files to make. After the lower grades are filled to their new limit of three hundred, it will, of course, take longer to reach that rank, though even then the promotion will be fairly rapid. As the pay of all officers has been increased by another bill, the young doctor entering the service will now get $2,000 upon appointment, $2,400 as a captain, $3,000 as a major, $3,500 as a lieutenant-colonel, $4,000 as a colonel, with 10 per cent. increase for each five years' service up to twenty years, though the maximum pay of majors is limited to $4,000, lieutenant-colonels $4,500, and colonels $5,000. This is not unattractive in view of the fact that a house, light, and fuel are supplied to all, and horses when needed by captains and lieutenants, and that there is a retired pay of 75 per cent. if disabled. Though it is far less than what is received by men of equal ability who are the leaders of the civil profession, it is more than the income of 80 or 90 per cent. of general practitioners.

There was formerly no chance for many of the juniors to attain the rank of lieutenant-colonel, and a few could not become majors before retirement. In spite of that fact Congressman Mann stated in the House that certain line officers had told him that the bill was unjust to them, as it gave medical officers too rapid promotion! It is now quite evident where the public can place the blame for opposition which has caused the long delay in increasing army efficiency.

The new bill creates a Medical Corps, which, with the Medical Reserve Corps, the Hospital Corps, Nurse Corps, and Dental Surgeons, constitutes the Medical Department. All the old absurd titles are abolished, and the medical officers are legally given the titles of their rank like other officers. The change has been advocated for a half century, but has always been opposed by those uxorious line officers who never went to war, but who believed that the army doctor's chief duty was to relieve colic among the babies of army posts—a duty not requiring rank. Congress has wisely ignored these unprogressives because it has at last realized that in his main duties of preventing disease, managing hospitals and the Hospital Corps, and the thousand and one things inseparable from what is called "Military Medicine," rank is an essential without which a medical man's opinion on army matters is not given the slightest weight.

The increases are spread over several years, as it would be clearly impossible to obtain so many men in one year, particularly as the present high standard will be maintained, but after all the vacancies are filled there will still be need of more men, as 444 medical officers cannot possibly suffice for an army of 100,000—but that increase is for future Congresses.

The Medical Reserve Corps is to be filled by commissioned first lieutenants, who will be paid only when in service, and it is hoped that they will form a nucleus in civil life for a large body of specialists for professional work in hospitals in time of war—providing they do not all get the notion that their proper place is chief surgeon of an army corps, and then use political influence to obtain commissions to do work for which they are not competent, as too many men without experience, and even nonpractitioners, did in 1898. In war the future professional military medical officer will be engaged wholly in executive and sanitary work, and the hospitals will naturally fall to those hastily called from civil life.

It was absolutely impossible to make any change in the law regulating the medical officer's authority. That must come in time, for the only law of this sort at present in the revised statutes requires the medical officer to attend to the families of married officers and soldiers when his military duties permit, and nowhere does it describe those duties. In addition there is no provision for giving medical officers more complete control over the management, discipline, and inspection of hospitals, which are occasionally dreadfully handicapped by the interference of line officers ignorant of the needs. Nor has any change been made which will visit punishment upon medical or line officers who allow disease to kill more than the enemy. But public opinion will compel such changes in time even if line officers object. A good beginning has been made, although other nations have gone much further.

THE QUESTION OF ANESTHETICS.

THE medical profession of Great Britain, judging from reports which have appeared recently in medical journals, seems to be somewhat profoundly stirred by the large number of deaths which have occurred within recent years as the result of the administration of anesthetics. From an article by Dr. F. J. Waldo in the *Medical Press and Circular* of March 18 we learn that the annual reports of the

Registrar-General for England and Wales for the five years, 1902-6, give the number of deaths under surgical anesthesia as 148, 146, 154, 155, and 183 respectively; but Dr. Waldo says that these figures are much below the actual number, as only a small proportion of the deaths under anesthesia ever come to the notice of coroners or registrars. During this same period there were several deaths from this cause in Guy's Hospital, and some of the more sensational lay journals have seized upon the opportunity to write up the cases in a lurid way. To some extent, however, it seems that there have been grounds for their declamatory articles, for although the accounts given have undoubtedly been grossly exaggerated, more cases of fatal results from the employment of anesthetics have happened than might have been reasonably expected. In fact, there would appear to be small room for doubt that some of the deaths might have been avoided.

For many years vehement discussions have been carried on at intervals with regard to the comparative merits of chloroform and ether in the production of surgical anesthesia. Of course the matter has not been settled, and the advocates of chloroform and of ether, respectively, are as eager to uphold the virtues of their particular choice as ever. Into this question it is not proposed to enter here, nor is there the space to dwell upon the methods of administration. Still, it may be said that the open mode of employing anesthetics seems to be gaining favor in Great Britain. A meeting of considerable interest in connection with the matter of anesthetization was held by the Medico-Legal Society of London, on March 24, at which many prominent lawyers and medical men were present. The meeting was called to discuss a paper read at a former meeting by Dr. L. Freyberger, and was notable for the reason that Dr. Frederic Hewitt, almost the best known anesthetist in Great Britain, expressed it as his opinion that the majority of deaths from or under anesthesia were preventable, and if death took place it was, as a rule, not the patient or the operator who was at fault, but the anesthetist. His argument, in short, was that in all cases in which an anesthetic is administered, it should be administered by a man who has been thoroughly trained in the work, and not, as is too frequently the case, by dentists or by practitioners who have had no previous proper training in the administration of anesthetics. Dr. Hewitt suggested that the two following motions be forwarded in the name of the British Medico-Legal Society to the General Medical Council and to the Privy Council respectively: (1) That in view of the importance of the administration of anesthetics the society is of opinion that it is highly desirable in the public interest, that every member of the medical profession before he is registered shall have received instruction in the administration of anesthetics. It, therefore, earnestly begs the General Medical Council to consider whether they can see their way to include a course of instruction in anesthetics among the requirements in regard to professional education. (2) That as the administration of any drug or drugs with the object of producing generalized insensibility to pain or actual unconsciousness for any medical or surgical operation, or during childbirth, cannot be safely undertaken without medical knowledge and skill, it would be desirable that the administration of any drug or drugs with either of the aforesaid objects by any person other than a duly registered medical practioner or some one acting immediately under his supervision, direction, and instruction, be made a penal offense. Both of these propositions were carried at the meeting. Among the reforms suggested by Dr. Waldo, in the article above referred to, were that a complete record be kept of the details of every case of the administration of anesthetics, that the coroner be notified of all deaths occurring at any stage of general anesthesia, and that coroners be required to hold a public inquiry in every case of death during anesthesia.

In Great Britain it appears that any person, whether qualified or unqualified, experienced or inexperienced, reputable or disreputable, may administer an anesthetic, and provided that he does this to the best of his ability and with no unlawful motive he is not likely to be punished or even blamed if his patient dies as the result of the anesthetic given. In this country also, the law generally as regards the giving of anesthetics is decidedly lax. It may be stated with little fear of contradiction that the average physician in the city or the general practitioner in the country has not had the amount of training or of experience that he ought to have had to enable him to administer anesthetics with safety. No one can cavil at the proposition then, that every member of the medical profession should have received instruction in the administration of anesthetics before he is admitted to practice. Likewise, every physician will agree with the view that no layman should be allowed to administer anesthetics. That skill and experience go for much in administering anesthetics was clearly shown by an analysis of seventy-four cases reported in British journals during a year. Out of this number five happened in the hands of men who were constantly engaged in giving anesthetics, and the other sixty-nine in the hands of men with whom it was only an occasional duty. Perhaps Dr. Hewitt laid too great stress upon the necessity of the anesthetist possessing knowledge and experience, and ignored too much the personal factor, when he declared that nine out of ten of deaths from anesthesia were preventable, but there is no doubt whatever that fewer fatalities would happen if the administration of anesthetics were restricted to those who have had training in the proper methods of so doing.

The Treatment of Suppurative Conditions.

The recent changes in the treatment of local surgical conditions have usually been in the direction of imitating the natural processes that appear in the organism in answer to an injury or an infection. Such changes have been the more successful, the more closely the phenomena of repair have been studied and understood. Dr. E. Miller (*Münchener medizinische Wochenschrift*, April 28, 1908) has found that the pus of acute abscesses is very rich in ferments which break down the portions of the neighboring tissues and lead to the increase in size

of the inflammatory foci. He, therefore, conceived the idea of treating such foci by the addition of fluids rich in antiferments. Dr. Peiser has applied this idea in practice, introducing the blood serum of the patient into the abscesses. This procedure led to disappearance of pus and rapid healing in all abscesses, lined by smooth walls, the effect of the antiferment fluid being limited to the tissues in contact with it. The treatment of undermined abscesses in this way also gave gratifying results, if care was taken to expose the inflamed tissue by wide incisions. The procedure is the analogue of the treatment of cold abscesses by the introduction of iodoform emulsions that attract the ferment-bearing leucocytes, thus hastening the resolution of the disease focus. It seems logical enough to deserve extended trial in the hands of other surgeons.

Sympathetic Ophthalmia.

Many unsuccessful attempts have been made to explain the strange appearance of a destructive inflammatory process in one eye in consequence of a previous similar lesion in the other, which is the usual cause in cases of so-called "sympathetic ophthalmia." Clinically it is found almost impossible to foresee this turn of affairs, and until lately the pathology of the affection has been equally obscure. Dr. George Lenz (*Berliner klinische Wochenschrift*, April 27, 1908) says that the constant pathological findings consist in such cases in the infiltration of the uveal tract, leading to great thickening of the choroid, and to the destruction of the sclerotic coat from within outward; the exudative processes that are sometimes found are not typical of this condition, being due to the presence of a mixed infection. Such infiltration consists of small lymphocytes, polymorphonuclear eosinophiles, and so-called "epithelioid" cells. In general, the picture is distinctive enough to warrant the conclusion that sympathetic ophthalmia is due to a specific infectious agent, especially as the pathological findings in the later affected eye are similar to those in the eye that is originally attacked. The author thinks that this infection is carried from one eye to the other by the bloodstream, the absence of pyemia being probably due to the great specificity of the organism, limited as it is to the tissues of the eye alone. It may be hoped that such observations will soon reach the stage of assisting the ophthalmologist in foretelling the probable occurrence of sympathetic ophthalmia, and in preventing it by early removal of the originally affected eye.

The Final Results of Tracheotomies.

Discussions in reference to the relative values of tracheotomy and intubation continue to be frequent in Europe, where O'Dwyer's invention has not found such wide application as in his native America. Writing in the *Deutsche medizinische Wochenschrift*, April 23, 1908, Dr. R. Wolf considers the final results of tracheotomies as observed in Trendelenburg's Clinic at Leipsic. Of the 404 tracheotomized children in the period of twelve years, 264 were discharged cured, the high mortality figures being due to the fact that many patients reach the clinic in a moribund condition. Dr. Wolf has traced 173 of the discharged children, and found 145 of them, or 85.5 per cent., free of all symptoms whatever. Twenty-four patients, that is, 14.2 per cent., suffered slight inconveniences, such as hoarseness, tendency to a mild laryngitis, frequent attacks of "colds," etc., most of which complaints, however, could be explained by other causes than the tracheotomy. Seven patients, or 4.1 per cent., suffered more severely, four of them showing signs of tuberculosis, which in three cases could be traced to a family predisposition to the disease. Thus, cicatricial stenosis of the larynx, which many claim to be a frequent sequel of tracheotomy, has not been observed in any of the 173 tracheotomized children. Other unpleasant sequels are no more frequent than after intubation, and the advantages of the latter, therefore, are to be defended on other grounds than the alleged bad results of tracheotomies.

A New Aspirator and Its Uses.

Aspiration has long been of value in surgery, and many aspirators have been invented of which Potain's and Dieulafoy's are universally used. Recently the Frenchmen have been employing a simple apparatus which can be used wherever there is running water. An air-pump is attached to a faucet and then connected to a large glass bottle by an incompressible rubber tube; a second tube runs from the bottle and has a perforated trocar attached to its end. By turning on the water a vacuum is produced in the bottle. In *La Presse Médicale*, March 28, 1908, F. Legueu mentions the uses of this apparatus. Because of the continuous and strong suction produced by it he recommends it as a hemostatic in bladder work when packings would obscure the field of operation. In buccopharyngeal work the anesthetist should hold it in the patient's mouth, thus collecting the blood and preventing it from running down the trachea. He recommends it especially for the evacuation of fluids, as in large ovarian cysts when, owing to the complete removal of the fluid, there is less liability of any of the latter getting into the abdominal cavity than when the ordinary trocar and cannula is used without suction. In septic collections, such as empyema, suppurating kidney, pyosalpinx, suppurative cholecystitis, or appendical abscess, he believes the use of the apparatus will enable one to remove all the pus first without contaminating the healthy tissues, after which the routine measures for drainage can be employed.

News of the Week.

In Honor of Professor Fitz.—The issue of the *Boston Medical and Surgical Journal* of May 7, 1908, is dedicated to Dr. Reginald Heber Fitz, Hersey Professor of the Theory and Practice of Physic in Harvard University, in honor of his sixty-fifth birthday, which was celebrated on May 5. The original articles, twenty-five in number, are contributed by Dr. Fitz's former house pupils at the Massachusetts General Hospital and assistants in the Department of the Theory and Practice of Physic, Harvard University. The number opens with an excellent portrait of Dr. Fitz and a sketch of his medical career since beginning the study of medicine under Jeffries Wyman in Cambridge in 1864. There are thirteen lithographic plates illustrating pathological conditions and blood findings. There is also a bibliography of Dr. Fitz's contributions to medical literature. The editor contributes an interesting historical account of the growth of the "Festschrift" custom in America, beginning with the "Wilder Quarter-Century Book" in 1893.

The "Woman's Medical Journal."—The April

issue of this journal is a special number devoted to the annual meeting of the Women's Medical Society of the State of New York. It contains the address of the president of that society, Dr. Sarah R. A. Dolley of Rochester, together with many of the papers read at that meeting by women physicians occupying positions of eminence in the profession. The frontispiece is a photograph of Dr. Dolley.

"American Health" is the title of a new bimonthly journal issued as the official organ of the American Health League. This organization is the outcome of a union of the Committee of One Hundred on National Health of the American Association for the Advancement of Science and of the Public Health Defense League. Whatever other good comes from the amalgamation of the two bodies there is a great gain in brevity of title. The Public Health Defense League was founded in November, 1906, for the purpose of suppressing the illegal and fraudulent practice of medicine, the improper use of the United States mails in the transmission of immoral and obscene advertisements and literature, and for the conservation of public health and morals. The Committee of One Hundred was organized at the meeting of the American Association at Ithaca in June, 1906. As the two organizations had in the main the same objects, and many of the members of one body were members of the other also, it was decided to unite the two societies, the amalgamation being formally accomplished in November, 1907. The editor of the official journal of the Society is Dr. Richard Cole Newton of Montclair, N. J. The office of publication is at 69 Church street, New Haven, Conn.

An International Attack on the Opium Evil.—President Roosevelt has suggested to Congress the appropriation of $20,000 for the salaries and expenses of three commissioners and a secretary, who shall for this government inquire into the opium evil. A letter from Secretary Root, accompanying the President's note, suggests that each country which has signified to the United States its willingness to make such an investigation appoint commissioners who shall make inquiries in their own countries. He further proposes that all these commissioners meet at Shanghai, China, on January 1, 1909. This assemblage at Shanghai will then decide what shall be done to eradicate the opium evil.

Osteopaths Recognized as Legal Practitioners.—The Supreme Court in Brooklyn has ordered the Health Department to register an osteopathic practioner in the list of physicians of this city and to accept from him death certificates the same as in the case of physicians who are not osteopaths. The Health Department refused to register an osteopath on the contention that he was not a physician and did not prescribe medicine. The court holds that osteopaths are physicians and practise medicine, and except for restrictions put upon them by Chapter 344 of the Laws of 1905, prohibiting them from administering drugs and performing surgery with the use of instruments, they are entitled to all the rights and subject to all the privileges of physicians and medical practitioners.

Criticism of the Basle Nomenclature.—Dr. Hermann Triepel, professor of anatomy at the University of Breslau, submitted to the Anatomical Society at its twenty-second annual convention in Berlin, on April 22, 1908, a memorial on anatomical nomenclature, in which he expressed his agreement with all the views and suggestions put forward by Dr. Achilles Rose, of this city, since 1894. He also confirms the statement of Dr. Rose that the work of the Commission on Nomenclature of the German Anatomical Society, now known by the designation of the Basle Nomenclature or [B. N. A.], is not perfect; that it is, indeed, quite defective in regard to language, and that a thorough revision of it is desirable. During the last few years quite an appreciable number of books have been published, notably also in America, which have adopted the Basle nomenclature, and Triepel is of the opinion that the unopposed dissemination of the imperfections in medical nomenclature should be checked. In agreement with Rose, Triepel considers it an important requisite to secure the assistance of Greek colleagues for the linguistic revision of the [B. N. A.].

Clinical Week at Boston University.—The faculty of the Medical School of Boston University has decided to arrange for a short course of general clinical instruction, to be held during commencement week, June 1 to 6, 1908. More than thirty different professors and lecturers will participate, and general medicine, surgery, gynecology, and the various specialties will all be represented, as well as other miscellaneous subjects. The course will be so arranged that each attendant can be present at every exercise, and can thus obtain a survey of a large field in a comparatively short time. Sessions will be held at the Medical School buildings, at the Out-Patient Department of the hospital, and in the amphitheater and the clinical lecture room of the main building of the hospital. The course will be open without fee to graduates of any reputable medical college. Further information and tickets admitting to all sessions may be obtained from the registrar, Frank C. Richardson, M.D., 80 East Concord street, Boston.

Protection of New York Harbor.—The House of Representatives on May 15 passed Representative Greene's bill to protect the harbor of New York from deposits of injurious or unhealthy substances. It forbids scows to receive garbage without first getting a permit from the supervisor of the harbor, defining the limits within which the refuse may be dumped. It empowers inspectors to arrest persons without process for violations. The inspectors may also enter manufacturing and gas and oil works to see that no sludge or acid is permitted to run into the tidal waters of the harbor.

Endurance Tests for Army Officers.—President Roosevelt has approved a general order prescribing new physical tests for army officers. The officers will be obliged to ride thirty miles a day for three successive days, on two of the days within seven and a half hours, on the third day within six hours. Officers of the Coast Artillery who were exempted from the former riding test, will have to walk fifty miles in twenty hours over a period of three consecutive days.

The Plague in Venezuela.—The plague situation in Venezuela is believed to be growing more serious, though owing to the policy of secrecy and denial adopted by the government of that country it is impossible to obtain any definite information. On this account the port of New York has declared quarantine against all vessels from Venezuela. The disease is spreading from La Guayra to the other coast towns, several cases having occurred in Puerto Cabello.

Measles in Philadelphia.—An extensive epidemic of measles is prevalent in Philadelphia, 468 new cases having been reported for the week ended May 16. It is estimated that there have been between 5,000 and 6,000 cases throughout the city. Fortunately there have been only ten deaths.

Tuberculosis of the Lungs and Diabetes.—In the report of the Medical Section of the New York Academy of Medicine for April 21, published in the issue of May 16, at which a discussion on this subject took place, part of the remarks of Dr. A. Mayer was erroneously attributed to Dr. Stern. The views expressed in the entire paragraph were those of Dr. Mayer.

Tilley's Disease of the Nose and Throat.—In the review of this work in the issue of April 25, the name of the publisher is given as H. K. Gowers. This was a *lapsus calami* of the reviewer, the publisher being H. K. Lewis, 136 Gower street, London.

A New Science.—The Boston *Morning Herald* prints as a cable dispatch from Paris the important information that ten women are working at the Pasteur Institute. "One is an American who is studying a science known as anaphylasey, which treats of nervous sensitiveness under the influence of serums." Another American student married a colleague and has since deserted the institute.

Nurses' Banquet.—The eighth annual banquet of the Mary Thompson Training School for Nurses Alumni Association was given recently at the Grand Pacific Hotel. Miss Carrie Miller was toastmistress, and the address of welcome was delivered by Miss Mary Lindsay.

Cocaine Dealer Convicted.—A druggist in Mott street, New York, who is credited with selling cocaine to many women of Chinatown, was convicted recently in the Court of General Sessions of selling the drug without physicians' prescriptions. He was sentenced to one year's imprisonment and to pay $1,000 fine. This is the first conviction of the kind under the new law.

Rules for Chicago Hospitals.—A proposed ordinance in Chicago, drafted by Dr. George Hunt, of the City Health Department, provides for an advisory board of three experts, whose duties shall be to regulate hospitals, provide requirements for new institutions, and otherwise supervise places where the sick are cared for. This ordinance has been recommended for passage by the Council Committee on Health.

Kansas for Reed.—During the recent annual meeting of the Kansas State Medical Society at Iola, Dr. Lutz of Kansas City introduced a resolution, which was passed unanimously, expressing the approval by the society of the candidacy of Dr. C. A. L. Reed of Cincinnati for United States Senator from Ohio.

Prof. August Martin of Berlin, Germany, who is in Chicago to attend the meeting of the American Medical Association, was recently given an informal dinner by the Chicago Gynecological and Surgical Societies, and in a short talk complimented the Chicago surgeons on the progress made by the medical profession in America. Professor Martin is conducting a series of clinics at the different hospitals.

Dr. B. G. A. Moynihan of The Leeds Infirmary, England, recently read a paper on "Surgical Treatment of Gastric Ulcer" before the Chicago Medical Society, by invitation. Dr. Arthur D. Bevan, in introducing Professor Moynihan, said that medicine to-day is international, and that here in America we derive our inspiration largely from Great Britain and Germany.

The German Poliklinik of this city celebrated the silver anniversary of its founding with a dinner at the Waldorf-Astoria on May 16. The four surviving doctors of the original fifteen who established the institution twenty-five years ago were the guests of honor. These were Dr. Samuel Kohn, Dr. H. J. Boldt, Dr. A. H. von Ramdohr, and Dr. Ludwig Weiss. Frau Simon Steiniger, on behalf of the women interested in the Poliklinik, presented to the officers a silver wreath containing the names of the founders. In 1883, the first year of its existence, 2,869 persons were treated at the clinic and 8,700 calls were made. Last year 38,739 cases were treated and 82,683 calls were made.

Western Canada Medical Association.—A movement is on foot in the western Canadian provinces to organize a medical society for practitioners in that region. The existing local and provincial societies would become affiliated with the Western Association, and this in turn would be a part of the Dominion Medical Association. At a recent meeting of the Winnipeg Clinical Society a resolution was adopted "that a committee be appointed from this society to approach other societies in western Canada to ascertain their opinion regarding the formation in western Canada of a Western Canada Medical Association."

Society for the Study of Inebriety, Alcohol, and Narcotics.—The thirty-eighth annual meeting of this society will be held in Chicago June 2, 3, and 4, from 9 to 12 A.M. The special work of this society is the scientific study of the problems relating to alcohol and inebriety. A "temperance lunch" will be served Wednesday, June 3, at 1 P.M., which will be the occasion for an informal discussion of the alcoholic subject by the leaders of the profession. Dr. T. D. Crothers of Hartford, Conn., is secretary of the society.

American Gastroenterological Association.—The eleventh annual meeting of this association will be held in Chicago on Monday and Tuesday, June 1 and 2, under the presidency of Dr. John P. Sawyer of Cleveland.

National Association for the Study and Prevention of Tuberculosis.—The fourth annual meeting of this association will be held at the Auditorium Hotel, Chicago, on Friday and Saturday, June 5 and 6. The executive secretary, to whom application should be made for further information, is Mr. Livingston Farrand, 105 East Twenty-second street, New York City.

The Physicians' Club of Chicago.—At the annual meeting of this club, held May 15, the following officers were elected: *Chairman*, Dr. Henry B. Favill; *Secretary*, Dr. Edwin B. Tuteur; *Treasurer*, Dr. C. L. Mix; *Directors*, Drs. Favill, George E. Baxter, D. A. K. Steele, Alfred C. Croftan, and Charles E. Paddock.

The Worcester, Mass., District Medical Society.—The annual meeting of this Society was held May 13. The following officers were elected: *President*, Dr. William G. Reed, Southbridge; *Vice-President*, Dr. Lemuel F. Woodward; *Secretary*, Dr. G. E. Emery; *Treasurer*, Dr. George O. Ward; *Orator*, Dr. M. F. Fallon; *Librarian*, Dr. Merrick Lincoln.

Los Angeles to Invite the A. M. A.—According to the local papers the physicians of Los Angeles are very anxious to entertain the American Medical Association in that city in 1909, and it is proposed to send a committee to Chicago to press the invitation.

The Berkshire Medical Society.—At the annual meeting of this society held at Pittsfield, April 30, the following officers were elected: *President*, Dr. John L. Hassett of Lee; *Vice-President*, Dr. H. B.

Holmes of Adams; *Secretary,* Dr. I. S. F. Dodd of Pittsfield; *Treasurer,* Dr. William L. Paddock of Pittsfield.

The Windham County (Conn.) Medical Association met in annual session at Putnam on April 23. The following officers were elected: *President,* Robert C. Paine, Thompson; *Vice-President,* John Welden, Willimantic; *Secretary,* James L. Gardner, Central Village; *Councilor,* C. C. Gildersleeve, East Woodstock.

The Litchfield County (Conn.) Medical Association.—At the one hundred and forty-fourth annual meeting of this association, held at Winsted on April 28, the following officers were elected: *President,* Dr. I. L. Hamant, Norfolk; *Vice-President,* Dr. S. G. Howd, Winsted; *Clerk,* Dr. F. H. Lee, Canaan; *State Councilor,* Dr. E. H. Welch, Winsted; *Committee on Membership and Ethics,* Drs. J. Swett, New Hartford, C. I. Page, Litchfield, H. D. Moore, Torrington.

The Middlesex (Mass.) North District Medical Society met in annual session at Lowell on April 29. The election of officers resulted in the following choice: *President,* Dr. W. B. Jackson; *Vice-President,* Dr. C. A. Viles; *Treasurer,* Dr. T. B. Smith; *Secretary,* Dr. A. R. Gardner.

The Worcester (Mass.) North Medical Society held its fiftieth annual meeting at Fitchburg on April 28. The following officers were elected for the ensuing year: *President,* Dr. John G. Henry of Winchendon; *Vice-President and Treasurer,* Dr. Eustace L. Fiske of Fitchburg; *Secretary,* Dr. Walter F. Sawyer of Fitchburg; *Commissioner of Trials,* Dr. L. G. Chandler of Townsend; *Councilors,* Drs. E. P. Miller and F. H. Thompson, Sr., of Fitchburg, C. E. Bigelow of Leominster, and E. A. Sawyer of Gardner; *Nominating Committee,* Dr. E. P. Miller of Fitchburg; *Alternate,* Dr. E. A. Sawyer of Gardner; *Supervisor,* Dr. E. P. Miller of Fitchburg; *Censors,* Drs. A. H. Pierce of Leominster, J. B. Donnelly of Gardner, H. W. Page of Baldwinville, and E. J. Tully of Fitchburg; *Librarian,* Dr. A. P. Mason of Fitchburg; *Library Committee,* Drs. L. F. Baker and F. H. Thompson, Jr., of Fitchburg, and A. F. Lowell of Gardner.

The Independence County (Ark.) Medical Society held its annual meeting at Batesville the last week in April. The following officers were elected: *President,* Dr. C. A. Hinkle; *Vice-President,* Dr. Kennerly; *Secretary,* Dr. Lawrence; *Treasurer,* Dr. Hodges of Sulphur Rock; *Delegate to the State Society,* Dr. Gray of Cave City; *Alternate,* Dr. Lawrence.

The Nevada County (Ark.) Medical Society, at its annual meeting at Prescott during the last week in April, elected the following officers for the year: *President,* Dr. Adam Guthrie; *Vice-President,* Dr. S. J. Hesterly; *Secretary,* Dr. C. C. Purtie; *Delegate to the State Society,* Dr. J. S. Chastain.

The Dickinson and Iron Counties (Minn.) Medical Society held its annual meeting at Crystal Falls during the last week in April. The following officers were elected for the ensuing year: *President,* Dr. J. B. Brasseur of Norway; *Vice-President,* Dr. A. M. Darling of Crystal Falls; *Secretary and Treasurer,* Dr. H. A. Newkirk of Iron Mountain.

Bequests to Hospitals.—By the will of the late John A. Brill, of Philadelphia, the sum of $5,000 is bequeathed to the German Hospital, $3,000 to the Home for Incurables, $5,000 to the Hayes Mechanics' Home, $5,000 to the White Haven Sanitarium for Poor Consumptives, and $2,000 to the Home for Crippled Children. By the will of the late Joseph Cannon, of Philadelphia, his estate, amounting to $75,000, is, on the death of an aunt and a sister, to be divided among seventeen charitable institutions, as follows: Bethesda Children's Home, Children's Hospital, Episcopal Hospital, Foster Home, German Hospital, Germantown Hospital, Germantown Relief Society, Orphans' Home and Asylum for Aged of the Lutheran Church, Masonic Home of Pennsylvania, Methodist Episcopal Home for the Aged, Methodist Episcopal Hospital, Methodist Episcopal Orphanage, Odd Fellows' Home, Samaritan Hospital, Southern Home for Destitute Children, Woman's Hospital of Philadelphia, and Children's Homeopathic Hospital. By the will of the late Sarah Reeves, of Philadelphia, the sum of $5,000 is bequeathed to the Episcopal Hospital, for the endowment of a free bed, and $500 to the Home for Consumptives.

Northwestern University Medical School, Chicago, Illinois.—Dr. A. W. Meyer of the University of Minnesota, and formerly of Johns Hopkins, has accepted the professorship of anatomy, and Dr. A. N. Richards of the College of Physicians and Surgeons of New York City has been appointed professor of pharmacology in Northwestern University Medical School.

Obituary Notes.—Dr. J. Henry Scammell of St. John, N. B., died of pneumonia on April 25 at the age of thirty-eight years. He was born in St. John, and was graduated in medicine from McGill University in 1894. He was an ex-president of the St. John Medical Society.

Dr. Rufus Hall of Everett, Mass., died April 29 of pneumonia. He was born at Lynn, Mass., in 1869, and was graduated from Haverford College in 1892. His medical education was obtained at the Bellevue Hospital Medical College, where he was graduated in the class of 1896. His entire medical life was passed in Everett.

Dr. E. P. Russell died at his home in Middleburg, Vt., on April 29, at the age of sixty-eight years. Dr. Russell was studying at Castleton Medical College when the Civil War began, and served throughout the war, having been in twenty-three battles. After the war he completed his medical studies at the University of Vermont, graduating in 1866. He practised for six years at Council Bluffs, Iowa, but returned to Vermont in 1873 and took up practice at Middleburg.

Dr. Herbert H. Lyons of Fitchburg, Mass., died of pneumonia on May 6. He was born in Milford, and was graduated from the Harvard Medical School in the class of 1881. He had practised in Fitchburg since his graduation. He was also prominent in politics.

Dr. A. K. Carmichael of Trinidad, Colo., died of tuberculosis on May 1, at the age of fifty-four years. He was a graduate of the Cleveland, O., Medical College in the class of 1871.

Dr. Thomas L. Maddin of Nashville, Tenn., died April 28, at the age of eighty-three years. He was born near Louisville, Ky., September 4, 1824. He practised first in Alabama, but removed to Nashville in 1853. During the war he had charge of a large Confederate hospital in Nashville. He was for many years on the faculty of the University of Nashville, and up to his retirement, three years ago, was professor of diseases of the nervous system in that institution.

Dr. James T. Moore of Standish, Me., died suddenly on April 29. He was born in Standish on

June 3, 1841. He retired from active practice about two years ago.

Dr. Marcello Hutchinson of Lynnfield Centre, Mass., died on April 21 at the age of fifty-eight years. He was graduated from Harvard Medical School in 1877, and for many years was superintendent of the State insane asylum at Waterbury, Vt.

Dr. C. W. Ellis of Saginaw, Mich., died on April 18 at the age of forty-six years. He was born at Adrian, Mich., and received his medical degree from the Detroit College of Medicine. He had practised in Saginaw for nineteen years.

Dr. Lewis B. Parsell of Closter, Bergen County, N. J., died in the Nyack Hospital on April 22, at the age of fifty-six years. He was a graduate of the Long Island College Hospital in the class of 1881.

TENTH HARVEY SOCIETY LECTURE.

The last lecture of the present series given under the auspices of the Harvey Society was delivered at the Academy of Medicine on Saturday, May 9, by Professor E. A. Schäfer of the University of Edinburgh, the subject being "Artificial Respiration in Man."

The speaker began by pointing out the many exact measurements which were made use of in physiology, and then discussed the various instruments which had been devised to measure the amount of respired air. The ordinary spirometer, as such instruments were called, had been devised by Hutchinson. It was defective, however, because the inner cylinder was not equally balanced at the different levels. Hutchinson had employed it for measuring what he termed the "vital capacity." This was a ridiculous term, but probably adequate for an entirely useless measurement. The speaker then described the modified form of the instrument, in which the inner cylinder was exactly counterbalanced in all parts of its course.

Professor Schäfer gave a brief account of the historical development of respiratory measurements, stating that the most numerous as well as the most precise measurements had been made by Vierordt and Hutchinson in the middle of last century. There was an enormous variation in the amount of tidal air in different individuals, and in the same individual at different times. This depended on many factors, chief of which, however, was the rhythm of respiration. The average amount of tidal air per respiration varied from 250 to 1,000 c.c. The extremes reported were 50 to 1,640 c.c. Owing to the influence exerted by the rhythm on the amount of tidal air, it was much better to express the tidal air in a given amount of time; for instance, the amount respired in one minute. Even this was subject to fluctuations, but these were not so great. Vierordt gave 5,300 c.c as the average amount of tidal air per minute, and it was quite safe, the speaker said, to take about half a liter per respiration, and twelve respirations per minute, as the average ordinary requirement. Any method of artificial respiration which failed to supply this amount did not fulfill its purpose.

The speaker then referred to the appointment, in 1890, of a committee by the Royal Medical and Chirurgical Society of London, to study the relative merits of various methods of artificial respiration, with especial reference to drowning. Professor Schäfer was one of the committee. The first experiments had been made on cadavers, but it was soon found that these were unsuited to the investigation. It had, therefore, been decided to experiment on living subjects, both man and animals. It had soon become clear to the investigators that very little was known regarding the physiology of death from drowning. On studying this question themselves, it had been found that the amount of water in the lungs, in dogs, varied from 75 to 690 c.c., and that it was not in proportion to the size of the animal. The course of the resuscitation had been found to be unrelated to the amount of water taken in. The water, in fact, drained away very quickly, and some of it was absorbed by the blood-vessels.

While drowning, of course, was a kind of asphyxia, the two phenomena were not entirely alike. In drowning a number of factors modified the course of the process. The great rise of blood-pressure seen in ordinary asphyxia, for example, was absent in drowning. Drowning was also often associated with an increased secretion of mucus, and this fact was of great practical importance, for the mucus was churned up with the inspired water to a froth which sometimes blocked the alveoli so that it was impossible to force any air into the lungs. The experiments on dogs had shown that in some instances no amount of artificial respiration sufficed to resuscitate the animal. In animal experiments, it had been found that a small dose of atropine prevented this production of mucus, and Professor Schäfer jokingly suggested that before drowning a man should take an atropine tablet, and so lighten the labors of his rescuers.

The speaker then described the technique of the experiments carried out by himself and his assistants. Dogs were used, and drowning effected either by holding the animal with his head submerged in water, or by tubing the trachea, and then placing the end of the tube in water. The time was carefully noted, and tracings had been made of the respirations and of the heart beats and blood-pressure.

Professor Schäfer then demonstrated, by means of tracings, the effects produced by drowning, as well as the results of artificial respiration. The results, in dogs, had been very variable. After a drowning lasting two minutes it had hardly ever been possible for them to save the animal by artificial respiration. It was evident, therefore, that the time at one's disposal in a case of drowning was measured in parts of a minute. A few seconds might determine between life and death.

In considering the various methods of artificial respiration the speaker mentioned first the Marshall-Hall method, in which the patient was alternately placed on his side and then on his back. While on the back, firm pressure was made in the small of the back. This method had been published in 1857. In the following year, Silvester published another method. The technique of this was now so well known that it needed no further description. It was an attempt to imitate the physiological respiration, but sight was lost of the fact that the tissues in drowned persons did not respond normally.

In 1869 Howard, of New York, had described still another method. In this the patient was first placed on his belly, and pressed on the back. Then placed on the back, and pressed on his chest. Then the patient was grasped bodily around the chest by the operator and given a hard squeeze. The whole method was a pressure method. It had occasionally led to fractured ribs when the patients were old, or when the operator was too vigorous. All supine positions, the speaker said, were bad,

because water and mucus which accumulated in the throat prevented the air from gaining access to the lungs, and the same effect was produced when the tongue fell back.

The speaker then illustrated by lantern slides the method which he had found so successful. The patient was placed on his belly, with the face turned a little to one side. The operator knelt across him, at about the level of the buttocks, and placed both hands on the small of the patient's back. It was easy, in this way, to bring his body forward, and so throw its weight, in great part, on the patient's back. This produced a compression of the patient's abdomen, with a pushing up of the diaphragm, and a consequent forcing of air out of the lungs. The pressure was rather quickly released, thus permitting the air to rush in. This movement was to be repeated about every five seconds. It was found that this method supplied more tidal air even than normal respirations.

A comparison of the relative efficiency of the different methods of artificial respiration gave the following results:

Methods.	*Respiration Per Min.*	*Air Exc'ge Respiration*	*Exchange Per Min.*
Natural	13	450 cc.	5850 cc.
Silvester	13	175	2280
Howard	13	310	4030
Marshall Hall	13	254	3300
Prone Pressure	13	520	6760

At the conclusion of the lecture, Professor Schäfer gave a demonstration on a human subject, and then spoke of the previous work of Dr. Henry Baker, of the State Health Board of Michigan, which was very similar to the author's method.

After Professor Lee had moved the thanks of the Harvey Society for the speaker's masterly presentation, the chairman announced that the bound volume of the last year's lectures would probably be mailed to the members of the society next week. They would also be placed on sale at the same time. This closed the series of lectures for the present season.

Correspondence.

THE TWENTY-FIFTH GERMAN CONGRESS OF INTERNAL MEDICINE.

(From Our Special Correspondent.)

PRESIDENT'S ADDRESS—GYNECOLOGY AND INTERNAL MEDICINE—CARDIAC OVEREXERTION—FUNCTIONAL EXAMINATION OF THE INTESTINE—PATHOLOGY OF SYPHILIS—ELECTRICAL PROPERTIES OF IMMUNE BODIES — STAMMERING — HEART SOUNDS — HEMOPHILIA — RENAL TUBERCULOSIS—INJECTION TREATMENT OF SCIATICA—SUBJECTS FOR DISCUSSION IN 1909.

VIENNA, April, 1908.

THE opening session of the twenty-fifth Congress of Internal Medicine was held on April 6 in the presence of the Minister of Education, and of a very large number of medical men. The president, Prof. Fr. Müller of Munich delivered the opening address in which he greeted the representatives of the Government and spoke in very appreciative terms of the high position of the Vienna school in the history and development of the science of internal medicine. In discussing the Congress itself more particularly, he said that while it was evident that this had lost none of its interest and value, it was necessary to consider the question as to whether it could continue in its present form, or would require to be divided into special congresses, or several sections. The province of internal medicine had become so great that, as was the case with surgery, it was no longer possible to be thoroughly versed in all its branches. Specialization was useful and necessary, and much had been accomplished through it, while the public would always seek the aid of those who had acquired special skill in the treatment of certain diseases. Specialization should be opposed, however, if the specialists got out of touch with internal medicine as a whole, and if they had become specialists not because they were more capable in one field than in others, but only because they had some ability in one branch and none at all in others. Specialization of this sort was a danger to the patients.

The session of the first day was devoted especially to a discussion of the relations of the female sexual organs to internal diseases. The principal address was delivered by Prof. von Rosthorn, who confined himself largely to setting forth the scientific basis underlying this connection, as well as to indicating some of the most important disturbances in the functions of other organs which appeared to be originated by the sexual system. Lenhartz of Hamburg in speaking of the same subject aroused a good deal of interest by what he said in regard to treatment. He opposed protracted gynecological treatments and the tendency to perform very numerous operations, which he considered were not only unnecessary but also often injurious. Well-known gynecologists, he said, had sharply criticised overtreatment by specialists, and had pointed out that in the majority of cases the genital disorders which brought the patients for advice were not the causes but the concomitants of a disturbance of general health, and the consequence of nervous weakness which could be relieved through general measures rather than by local treatment.

Acute cardiac overexertion was discussed by Prof. Schott of Nauheim, who said that many years ago he had made experimental observations in this direction by having healthy, strong persons wrestle with each other until they got out of breath. It was possible to demonstrate dilatation of the heart in such persons both by percussion and with the Roentgen rays; as the result of these observations and of clinical histories, Schott considered that even in healthy individuals the picture of chronic cardiac overexertion might result in consequence of excessive muscular activity. For some years it was believed that both long-standing and acute overexertion of the heart could appear only in an organ already diseased either organically or functionally. The orthodiagraphic examinations of Moritz, Hofmann, and De la Camp had thrown doubt on the occurrence of acute cardiac dilatation as the result of bodily overexertion. The speaker then referred to a series of investigations by other clinicians which showed that overexertion might lead to chronic cardiac weakness in those previously well, and in the same category he placed the results obtained by Beck, Zuntz and Schumburg, Staehelin, and others, in experiments made on mountain climbers, bicycle riders, etc. He pointed out that the method of orthodiagraphy was liable to lead to errors in interpretation and did not yield altogether reliable results. Taking into account the possibilities of error, Schott had continued his former observations on wrestlers and by orthodiagraphic methods had been able to demonstrate enlargement of the heart caused in this way, so that he was led to his original conclusion to the effect that overexertion continued to the point of producing palpitation and severe dyspnea ultimately induced acute dilatation.

The following speaker, Dr. Herz, emphasized the fact that under some conditions the heart might suffer severely through interference with the space required for its normal action. Wrong position in writing and drawing diminished the size of the thoracic cavity and pressed the ribs of the left side against the heart. Cardiac disturbances in writers, physicians, and architects might be explained in this way. The hearts of dentists suffered as a result of the stooping position required in their work. Suitable treatment and attention to maintaining an upright position even while reading, writing, and drawing, would bring relief.

Prof. Schmidt of Halle spoke on the new methods of examining the functions of the intestine. As the result of his observations extending over many years, he had been led to undertake systematic examinations of the stools after several days' use of a definite test diet. The results of these examinations enabled the chaos of the various diarrheas to be divided into distinct types, recognition of which was often sufficient to enable a cure to be effected. He had also interested himself in the abnormal fermentative processes in the intestine and believed that many of the cases which had previously been regarded as instances of nervous diarrhea were really due to conditions of irritation and inflammation high up in the gut. Similar results had been obtained in his work on chronic constipation. In this condition, which formerly was always considered dependent on muscular or nervous weakness of the intestine, the primary cause was also to be found in disturbances of digestion, namely, in that digestion, particularly of the cellulose of the food, was too efficient. Schmidt, therefore, treated the condition by giving agar-agar to which a small amount of a vegetable extract had been added to stimulate the intestinal mucosa.

In the discussion that followed, Hecht of Vienna spoke of the microchemical reaction for mucus; Munz of Prague emphasized the importance of a fixed test diet when such examinations of the stool were to be made; Plönies of Dresden referred to the importance of the function of the intestine in killing bacteria; and Holzknecht of Vienna said that he had been able to demonstrate by means of the Roentgen rays the presence of accumulations of gas in the intestine. Strassburger of Bonn spoke of the ability of the intestine to regulate its bacterial content and Schüts of Wiesbaden recommended the use of a definite test diet.

Julius Schütz of Vienna discussed the testing of the functional efficiency of the stomach in infants. This he said had made little progress during the past twenty years. He believed that the chief reason for this lack of progress lay in the exaggerated importance which was ascribed to the so-called free hydrochloric acid, which he considered had little or no diagnostic significance. He had devised a method which indicated the degree of motility of the stomach; that is, its ability to pass on its contents into the intestine, and had also modified the chemical examination in such a way as to enable the presence of abnormal gastric fermentation to be ascertained. The superiority of this method over those in general use had been demonstrated clinically and it was to be hoped that the functional examination of the infant's stomach would soon be on the same basis as that of adults.

Prof. von Noorden stated that the treatment of mucous colic by means of a vegetable diet rich in residue which was recommended by Lenhartz and Moritz had already been suggested by him twelve years ago. At that time the measure had been opposed, and he was glad to see that it was now being received with favor.

The discussion of the present standpoint in regard to the pathology of syphilis, by Prof. Neisser of Breslau aroused much interest. The speaker first took up the discoveries that had been made in this field during recent years. He spoke of the discovery of the spirochete of syphilis by Schaudinn and stated that it might now be assumed beyond all doubt that this organism was the causative agent of the disease. He then mentioned Metchnikoff's discovery that monkeys could be infected with this organism and also referred to Wassermann's method of serum diagnosis, which he considered of the greatest importance. The present attitude was to make the diagnosis as early as possible and not to wait until the entire body was saturated with the poison. In other respects there was not much change and the clinicians still favored protracted intermittent treatment. In regard to serum treatment and protective immunization, he said there was nothing to report. This was a sad chapter that had to be passed over, and in spite of all efforts an immunity against syphilis had not yet been successfully demonstrated. He hoped, however, that the time would soon come when this question would not need to be considered at a medical congress, because the disease would no longer exist except in its earliest stages, and dissemination through the internal organs would no more be seen.

Landsteiner and Pauli presented a paper on the electric migration of immune bodies. The electrical condition of colloids was of great importance, and could be recognized by the direction of migration in the electrical field. Electronegative colloids moved to the positive pole and electropositive colloids to the negative pole. In addition to these there were others which were not transported in one dirction or the other, but were electrically neutral. The chief representatives of these colloids were albumins freed from their salts by careful dialysis. While pure albumin did not readily move in the electric field to an appreciable degree the addition of a trace of acid or alkali imparted an electric charge to it and it would then migrate to the negative or positive pole. Such substances might be called amphoteric colloids. The authors then discussed the reasons for the contradictory results sometimes obtained in such experiments which they thought were often to be explained by the use of unreliable methods. They further reported experiments made with ricin, abrin, and the agglutinin of chicken serum, by means of which the electrical behavior of these bodies was determined under various conditions.

Stern of Vienna read a paper on the pathogenesis and diagnosis of stammering. He said that in many cases this affection was not the result of a simple neurosis of coordination or spasm of the muscles of phonation, but was a form of compulsion neurosis depending on a concept of compulsion. In accordance with this view it was possible to obtain exceedingly good results by a suitable combination of exercises and psychical treatment even in the most severe cases.

L. Kürt spoke on the auscultation of the heart, saying that the intensity and situation of the heart sounds depended not entirely on the organ itself, but also on the capacity for vibration of the various media through which the sound waves had to pass on their way to the surface of the thorax. The first sound is to be heard distinctly in front as well as over a part of the left side, but the second sound is audible over a much more extensive area. In determining the outlines of the heart, it is of importance to estimate the intensity of the first sound, and the speaker outlined a method by means of which this principle could be applied as an adjuvant to percussion.

Siegel of Reichenhall described experiments on dogs in which he found that by exposing the animals to wet and cold it was possible to produce acute inflammatory changes in the nerves. If the animals were dried and rubbed immediately after the chilling no lesions were produced, but they appeared in the same animal if the experiment was repeated without the rubbing and drying.

Morawitz and Lossen of Heidelberg reported a case of hemophilia in which the clotting of the blood was retarded for from five to seven times the normal period. They concluded that this was the result of a deficiency in the production of fibrin ferment. Prof. F. Pick of Prague gave the history of a family of "bleeders." The individual he had observed had suffered from renal hemorrhages and was the only survivor of seventeen children, of which number most of the males perished during the war of 1866 from insignificant injuries such as scratches and thorn pricks.

F. Kornfeld spoke on renal tuberculosis, and said that he had found that a great deal could be accomplished in these cases by climatic, dietetic, open-air, and tuberculin treatment, as well as by carefully managed psychotherapy. Internal medicine, therefore, had a prominent place in the treatment of this affection, and should give way to surgery only when it seemed that the latter would be distinctly useful in the particular case under consideration.

Salomon and Przibram discussed the diagnosis of gastric carcinoma, saying that the demonstration of blood serum emanating from the ulcerated surface in the stomach contents was a valuable diagnostic aid. This could be done by adding some of the gastric juice to the serum of a rabbit immunized against human serum.

Lenhartz of Hamburg described the clinical picture of a catarrhal intestinal disorder of purely nervous nature. Rheinboldt of Kissingen expressed the opinion that habitual constipation was a nervous disorder which should be treated on this basis. Pariser of Hamburg advocated a modified form of Schmidt's test diet, and Delug of Vienna demonstrated an apparatus for testing the amount of fermentation in the intestine.

A. Bum of Vienna stated that he had treated one hundred and five cases of subacute and chronic sciatica by the injection of sterile salt solution into the nerves, and in 62 per cent. had obtained a permanent cure, and in 21 per cent. considerable improvement.

Prof. Jerome Lange of Leipsic presented a preliminary report on the treatment of tuberculosis with Jakob's tuberculin. In a number of cases of pulmonary tuberculosis the results had been excellent and an advantage of the method was that it could be used even in advanced and febrile cases.

The following subjects for discussion were proposed for the next year's meeting: The pathology of mineral metabolism; the dynamics of the thorax in relation to pulmonary physiology and pathology; the relations of gastric disorders to the circulation.

OUR LONDON LETTER.

(From Our Special Correspondent.)

PROGRESS AT THE WEST LONDON HOSPITAL—THE IRISH UNIVERSITY BILL—DYSENTERIC DIARRHEA—INCOMPLETELY DESCENDED TESTES — TETANUS NEONATORUM — SOLDIERS INVALIDED FOR TUBERCULOSIS—MODEL PUBLIC HOUSE—OBITUARY.

London, May 1, 1908.

Yesterday the Duke of Abercorn presided over the annual meeting of the West London Hospital, at which members of the staff referred in optimistic tone to the recent progress in medicine and surgery. Dr. Seymour Taylor said that notwithstanding the great advances in medicine during his connection with the hospital he believed they were on the threshold of still further most important discoveries. In regard to the work he always welcomed patients who were not poor enough to wait in the out-patient department and not rich enough to pay fees. This is a point on which he will hardly command the approval of general practitioners, who are quite ready to take charge of such cases on

most moderate terms and who think consultants do not properly appreciate their work. Hospitals are founded for the poor—not for the class which can pay the moderate charges of the general practitioner.

Mr. Swinford Edwards stated that this hospital was the first in London to adopt the antiseptic system and progress was still its motto. Its electrical and *x*-ray department was well equipped and conferred the greatest advantages. He instanced the wiring of fractures as assisted thereby and referred to operations performed under local anesthesia by lumbar puncture as among the recent triumphs of surgery.

The Irish University Bill is not receiving the general approval that was at first expected. On Wednesday, after a six hours' debate in Belfast, the higher education committee of the Presbyterian Church condemned it as "subversive of the principles of religious equality," and a commission of the Assembly was directed to take action accordingly. Discontent is also being expressed in other directions. It is alleged that promises made by the chief secretary in the House of Commons are not fulfilled in the bill as printed, and agitation as to this is threatened. Again, the endowments are held to be inadequate and the provision for the professorate insufficient. On the other hand the amount is represented as a Government bribe for Irish support. In the confusion caused by such contradictory statements a prior question deserves consideration. Is the increase of universities desirable in the best interests of education? Would not the money proposed to be expended be better devoted to the needs of the existing institutions? An excessive number of academical institutions does not tend to their efficiency. Anyone who has spent much time in Italy will admit that the disadvantages of too numerous universities are to be reckoned with. You may multiply students and graduates without conducing to scholarship or the happiness of the community. In the case of Ireland it is possible that competing institutions may not meet the difficulties of the situation.

A remarkable illustration of the difficult sanitary problems that occasionally call for solution was communicated to the Society for Tropical Medicine and Hygiene by Dr. W. T. Prout on the 15th ult. It was an outbreak of dysenteric diarrhea in a company of soldiers under his care when he was chief medical officer in Gambia. The water supply of the troops was from rain stored in large iron tanks which had been thoroughly cleansed towards the end of the dry season and the inlet pipes disconnected until the first shower washed the roofs. At the time of the outbreak the tanks were pretty full. No cases occurred among the civil population, and he was convinced the cause was within the barracks. The water was clear, sparkling, without bad taste or odor, but after investigating every other sanitary arrangement Dr. Prout was thrown back to this, as nothing else could be found as a cause. He had the manhole removed from one of the tanks and a bucket tilted over and dragged along the bottom. Finding a little sediment he ordered the water to be run off—reluctantly, as good drinking water is valuable in Bathurst. A deposit of greenish grey mud was collected, in which he found spindle-shaped bodies about the size and shape of oats, but slightly larger. He would not have know what they were had he not previously seen them under different conditions. Some time before, on riding to the hospital, he had witnessed a passage of locusts—millions settling on the trees, the ground and the roofs of the houses. In thirty-six hours every green blade had disappeared and the ground was brown and bare. He had noticed just such bodies then lying about; they were the fæces of the locusts and composed of the fibrous indigestible parts of grasses, with the silicious particles found in many. It was then clear to him that such fæcal deposits on the roofs of the barracks had become partly disintegrated and washed into the tanks with the next shower. Their specific gravity kept them suspended for a time, but they sank slowly and the irritation of the spicules passing through the alimentary canal caused the disease in the same way as the diamond dust of Egyptians or the ground glass of the Obeah man in the West Indies is known to do in a severer degree. Cleansing the tanks suppressed the outbreak at once.

Mr. Cantlie remarked that the outbreak resembled "hill diarrhea" in India, sometimes due to mica in the water after heavy rains. Dr. Hartigan said mica from disintegrated granite gave rise to such attacks in Hong Kong. Fleet-Surgeon Collingwood said that in Bermuda lime carried from the roofs by rain was blamed as the cause of similar outbreaks. Dr. Carnegie Brown said the first water from roofs was always impure and must he prevented from reaching the tanks.

Two papers on the treatment of imperfectly descended testicle read at the Harveian Society point to rather diverse conclusions, which were to some extent accentuated in the discussion. The first was by Mr. L. B. Rawling and was based on the investigation of 120 cases in St. Bartholomew's Hospital. In forty cases in which only one testis was improperly descended scrotal placement was attempted; in twenty-nine of these the ultimate result had been ascertained and in twenty-five it was failure, for the testis had retreated and become small and atrophic. In four cases the result was favorable. The other cases could not be traced. The conclusion was against this operation unless in exceptional cases in children under seven years. All evidence pointed to the conclusion that an inguinal testicle was a discomfort to the patient and liable to injury, infection, torsion, and even malignant disease. It was also useless when replaced. In fifty cases of all ages the testis had been removed without any interference with the bodily or mental development, the remaining organ being sufficient for its function. When both testicles are undescended the conclusion is different—the evidence showing that if replaced in the abdomen they are functionless, so that if scrotal placement fail it would be better to let them remain in the canal, where they are more likely to be functionally active than if replaced in the abdomen.

The second paper was by Mr. Edred M. Corner, who distinguished between imperfect descent and imperfect development, and said though something may be done for the former, little can be for the latter. By neglecting the question of future development operations give unsatisfactory results and often do harm. He said scrotal placement was the popular measure, but except in very carefully selected cases was a murderous operation; anatomically it seldom remained, physiologically it was largely converted into useless connective tissue. What then? Three lines of treatment remain. 1. To leave it alone until attacks of pain or inflammation occur, or hardening of the testis, or dilatation of the canal, or hernia. 2. Castration, only justifiable when the cord is twisted, the testis much sclerosed and the patient twenty-three years old or more. 3. Abdominal replacement, most useful from the patient's point of view, as it ministers to the development; its value lies in its internal, not its external secretion. By waiting until the indications named occur Mr. Corner thought few cases would eventually escape operation, especially as about 80 per cent. are associated with a hernial sac. Yet he admitted scrotal placement might be tried in young subjects under seven when the testis was movable and the imperfect descent slight.

Fuller's earth is said to be a very common application to the umbilicus of the new-born among the poorer class, and it has been suggested that this may be a cause of tetanus neonatorum. The idea was mentioned at the Society for the Study of Children's Diseases when Dr. P. Parkinson communicated a case of an infant of two weeks admitted with tetanic symptoms. It was ascertained that the mother had treated the umbilical wound with Fuller's earth and had lost another child when six days old from what was called lockjaw. In the case observed the wound looked unhealthy and discharged a thin, sticky fluid. A member objected to the explanation on the ground that the application was so excessively common, perhaps made in 95 per cent. of poor infants. On the other hand, it was said this possible source of tetanus had previously been recognized.

A preliminary report of the committee on the care of soldiers invalided and discharged for tuberculosis has been issued. The conclusion is reached that in recent cases the State should make provision for their care and treatment, and it is proposed that arrangements be made with civil sanatoriums to set aside a proportion of beds for these cases. It is estimated that £20,000 a year would suffice for such provision. This, you will notice, does not meet the needs of advanced cases, as they are ineligible for institutional treatment. Such cases are very pitiable, for a discharged soldier invalided cannot be expected to find occupation to support himself. Yet this report proposes no help for him. Perhaps the further report may find some way of helping him.

The Institute of Hygiene has converted a couple of rooms into a sort of "model public house," which was opened on Monday by Sir W. Bennett, and will be on view for a fortnight. There is no drinking bar, but a small barrier for service only, the customers having to sit at small marble-topped tables. Coffee, tea, cocoa, and all sorts of temperance beverages can be obtained. Food also is provided at some tables—cold viands,

sweets, fruits, etc. Games and newspapers occupy a central table. In short, everything is done in support of the view that brighter and better surroundings will promote temperance by meeting the demand for reasonable refreshment. Sir William Bennett, in declaring the exhibition open, agreed with the common saying that a nation could not be made sober by legislation, and the promoters of this exhibition advocated the betterment of the surroundings of the drinker. The essentials to this were abolition of the bar, food as well as drink being available, and the provision of means of amusement and recreation. Drs. C. Godson, Murray Leslie, Thresh, and Mayo Robson spoke in support of the scheme.

Dr. Charles Edward Underhill, president of the Edinburgh Royal College of Physicians, who had also been president of the Royal Medical, the Obstetrical and Harneian Societies (Edinburgh) died last Friday, aged 63. He was consulting physician to the Royal Hospital for Children and the Royal Maternity Hospital, had been lecturer on obstetrics and gynecology and Examiner in both colleges. He was a Tancred student at Cains College, Cambridge, and graduated there in arts (1867) and in medicine (1870). He was Fellow of both Edinburgh colleges and of the Royal Society. He began consulting practice in Edinburgh in association with the late Dr. Matthews Duncan, and when that eminent gynecologist came to London, succeeded to a large part of the practice. His position from the first was considered assured, and he never lost the confidence of his brethren as an able adviser in difficult cases and as a high-minded gentleman. His health had failed for several months, so that his death was expected by some of his intimate associates and medical friends.

Surgeon-General W. S. Oliver died on Monday at the age of 72. The late officer entered the army service in 1857 and retired in 1883. He saw a good deal of service in the Indian mutiny campaign and was mentioned in dispatches. He was M.D. of Halifax, Nova Scotia and also of St. Andrews.

Dr. William Thomas G. Woodforde, M.O.H. for the Berkshire combined sanitary district; vice-president, formerly president, of the Society of Medical Officers of Health, has died at the age of 81. A university college student, he took the M.B., London, in 1848, and the M.D. in 1852. Before going to the Berkshire district he had been M.O.H. and Public Analyst for Poplar.

Another death is that of Dr. Bowen-Davies, consulting physician to the Llandrindod Wells Hospital and author of the history of that spa. He was 60 years of age.

OUR LETTER FROM COPENHAGEN.

(From Our Special Correspondent.)

INAUGURATION OF THE NEW CLINIC OF THE FINSEN INSTITUTE—TECHNIQUE OF THE LIGHT BATHS—THE LIGHT TREATMENT OF ANGINA PECTORIS—APPENDICITIS—DEATH OF PROFESSOR LENNANDER.

COPENHAGEN, April 19, 1908

On April 14 the King and the royal family were present at the inauguration of the new clinic for internal diseases of the Finsen Light Institute of Copenhagen. The equipment of the clinic is very complete, about $100,000 having been spent on an establishment of only thirty-two beds and a large out-patient department. The new clinic had for many years been wished for by Finsen, but death prevented him from seeing his ideas carried out. In his last address to the board of directors of the Institute, which may well be considered as his scientific will, he expressed his belief that the therapeutic application of the universal action of light rays on the organism would lead to great results. He felt disposed to think that the light rays as a therapeutic means would be of the very highest importance for the treatment of chronic diseases, as diseases of the blood, of metabolism, of the circulatory system, etc. After Professor Finsen's death the director of the Finsen laboratory, Dr. K. A. Hasselbalch, took up the scientific investigation of the universal action of the light rays, and, as I have written you on two previous occasions, he claims to have demonstrated certain effects on the blood pressure and respiration. Certain nervous diseases and affections of the circulatory system, particularly angina pectoris, have been treated at the Institute in the way advocated by Dr. Hasselbalch, but the results claimed by the advocates of the treatment have been rather severely criticised and commented upon at two discussions in medical societies of this town. The task of the new clinic will therefore be to study the therapeutic value of light rays in different diseases without neglecting the application of other modern procedures of physic or dietetic treatment.

It is in this connection not without interest to notice what Dr. Oeigaard has recently published about the technique of the Finsen Light baths. Two large arc lamps are used, each of 75 amperes and 50 to 55 volt tension. The lamps are brought as near as possible to the patient, generally at a distance of 50 to 60 centimeters, when the temperature of the air at the surface of the body will be about 40° C. (104° F.). During the treatment the patient wears only a pair of very short drawers and a broad-brimmed straw hat with a linen curtain; a pair of dark goggles completes the outfit. The first ten or twenty minutes the patient is standing and turns from time to time in order to obtain uniform action on all parts of the skin. Then comes an irradiation of the lying patient, followed by a shower bath. The total duration of a single treatment is about half an hour. The whole cure consists of about nine simple treatments and lasts for about one month. The first effect of the irradiation is an erythema, which sets in some hours later. The patient himself feels the skin hot and swollen, but is only rarely inconvenienced by pricking or itching sensations. The erythema remains after the first treatments for 30 or 40 hours; later on only a feebler reaction takes place, while a chronic hyperemia of the skin develops and may be demonstrated for months after the cure is finished. Dr. Oeigaard also gives the results of the treatment of certain of the out-patients. In 34 out of 60 cases the absolute heart dullness decreased under the treatment. Fourteen patients suffered from edema; ten of these were completely relieved. The blood-pressure was determined by means of Hill and Barnard's sphygmomanometer. In all cases where the pressure was higher than normal an often very considerable decrease occurred during the cure. Of the subjective effects of the treatment Dr. Oeigaard first mentions a peculiarly agreeable weariness, most pronounced in women. The sleep is nearly always improved after the second or third treatment. Of seven cases where insomnia was the only indication for the trial of the treatment a satisfactory result was obtained in six of the patients.

The action of the new treatment on the painful attacks of angina pectoris is reported upon by Dr. H. Iacobæus. He has tried the light cure in 52 patients. In three cases the treatment had to be discontinued, in two the result was nil. In fourteen other cases the effect was slight or transitory, but in thirty-three of the patients the improvement was considerable. The conclusion is that the light bath cure has proved a reliable means of obtaining a more or less considerable and lasting improvement in the majority of patients with angina pectoris.

At the last meeting of the Copenhagen Medical Society Dr. L. Kraft read a paper on appendicitis. He had observed 247 cases and operated on about 200 of them. He thought it advisable to divide the clinical forms of appendicitis in four classes, the subserous, lymphangitic, gangrenous, and perforative, and described in what way one might diagnosticate between them. Rovsing's new symptom (which I described in a previous letter) was very valuable when it was present, but he had not been able to find it in several cases. On operation he had seen that when Rovsing's symptom was present the appendix was situated on the inner side of the cecum, but it was always wanting when the appendix lay laterally to the cecum. Professor E. A. Tscherning said that, judging from his experience of more than 800 cases, it was quite impossible to diagnosticate between the different classes as Dr. Kraft would do, nor had it any practical interest. What was important to determine was only whether there was a peritonitis and whether the peritonitis was circumscribed or spreading. One of the best signs of the last class was the one described by Lennander of Upsala, viz., the wandering painfulness for pressure of the abdominal wall. Professor Rovsing said he did not think that Dr. Kraft had sought for his symptom in the way he had described. As might be remembered, he had found the symptom very valuable in cases in which sensation of pain might be elicited by pressure on McBurney's point, while it remained uncertain what was the pathological process underlying the symptom. If it was an inflammation of the cecum or the appendix, a compression of the contents of the colon, brought about by applying one hand against the descending colon and letting it glide upwards against the left flexure, would cause a sudden darting pain on McBurney's point.

After several years' ill health, caused by a chronic endocarditis, Professor Karl Gustaf Lennander has

died, only 51 years old. In him the Swedish profession has lost one of its most prominent and widest known representatives. His chief interest centered in abdominal surgery and investigations into the sensibility of different organs, particularly the peritoneum. Amongst his very numerous and valuable literary contributions some have, I think, also appeared in American text books.

OUR CANADIAN LETTER.

(From Our Special Correspondent.)

NEW DEAN OF LAVAL UNIVERSITY, MONTREAL—OSTEOPATHY IN CANADA PROHIBITED—CANADIAN HOSPITAL ASSOCIATION —DEATH OF HON. DR. WILLOUGHBY—DR. BARKER HONORED— ESTABLISHMENT OF A PSYCHIATRIC CLINIC AT TORONTO.

Toronto, May 2, 1908.

Dr. E. P. Lachapelle has been appointed Dean of the Medical Faculty of Laval University, Montreal. The appointment is regarded with great favor. Probably no medical man in the Province of Quebec has devoted himself so disinterestedly for so long a period and in so many different directions to the promotion of the health and well-being of his fellows as has Dr. Lachapelle. To his efforts, more than to anyone else, is due the establishment of a Provincial Board of Health for Quebec province. He has been chairman of the board for more than twenty years and in spite of many discouragements he has done most efficient work for public medicine in his native province. Dr. Lachapelle was mainly instrumental in the building of Notre Dame Hospital and in later years presided for some time over the College of Physicians and Surgeons of Quebec.

Should osteopaths be allowed to practise in Canada? is a question that has been attracting considerable attention lately. It was expected by some that an effort would be made at the recent session of the Legislature of Ontario to amend the Medical Act so as to permit the registration of those who announce themselves as qualified to practise what is known as osteopathy. However, no such amendment was introduced and the probability now is that the osteopaths will be forbidden to practise further. A recent order has been issued that they are to be prosecuted under the Medical Act which makes it illegal for anyone not regularly registered as a member of the College of Physicians and Surgeons to practise medicine or surgery in Canada. For the past few years the osteopaths have not been disturbed, but of late they have become more numerous and hence the order to proceed against them.

The meeting of the Canadian Hospital Association at Toronto this year was well attended and the papers and discussions were highly interesting. The subjects brought before the meeting included "The Two vs. the Three Years for Nurses in Training," "The Relation of the Public to the Hospital," "Hospital Financing," "The Psychiatric Hospital," "The Care of the Tuberculous Patients," etc. The increased attendance at the meeting this year is regarded as evidence of the fact that these meetings form a common ground on which superintendents of hospitals may meet to consider the great problems relating to the care of the sick and the economical management of institutions.

An effort is being made in Ontario, where there are about seventy general hospitals under Government inspection, to make each institution an educational center. It is advocated that at every hospital a medical library and meeting place for medical men in the vicinity should be provided, where the records of interesting cases would be kept and laboratory facilities afforded. A movement has already been made in this direction in some places with most gratifying results. The development of the educational advantages which every hospital might afford would make, it is felt, each institution a miniature post-graduate school. The efforts that are being made to encourage this new movement are indicative of successful results following.

By the death of the Honorable Dr. W. A. Willoughby, M.P.P., of Colborne, the Canadian medical profession lost one of its best-known members. The deceased was born in Ontario, 1844, and graduated at Victoria University, 1867. Although a member of the Legislature of Ontario and during the past three years a member of the Ontario Government, Dr. Willoughby never ceased to take an active interest in his profession and never allowed his duties as a public man to interfere with his professional work. As a medical man he exercised great influence in the Legislature and faithfully upheld the rights and dignity of the profession. Genial in disposition, his range of acquaintance was large and his death has been noted with regret by many devoted and warm-hearted friends in all parts of Canada. Dr. Willoughby was greatly interested in the Legislature of Ontario in promoting reforms in matters relating to public health and improvements in the system of hospitals. He was a member of the medical commission which recently visited Europe for the purpose of investigating modern methods for the treatment of insanity. He strongly favored the establishment of psychiatric clinics, where the students of medicine might have advantages in the study of mental diseases. Dr. Willoughby, as an old practitioner of medicine, argued with great force that it would be of the highest advantage to the general practitioner to have improved clinical advantages for the study of mental and nervous diseases before entering the field of practice. The memory of the deceased will long be highly esteemed as that of a medical man who sought to utilize his public position solely for the benefit of his fellows.

Dr. L. F. Barker, professor of medicine in Johns Hopkins University, Baltimore, and formerly of the University of Toronto, was honored by Queens University, Kingston, on April 29, by having conferred on him the honorary degree of Doctor of Laws.

The Province of Ontario is shortly to have greatly improved accommodation for the proper and systematic treatment of incipient insanity. During the past year a medical commission was appointed by the Ontario Government for the purpose of making a thorough inquiry into the subject. The members of the commission were Hon. Dr. Willoughby, Dr. C. K. Clarke and Dr. E. Ryan, the first named being a member of the Government and the others being medical superintendents of two of the hospitals for insane in Ontario. The report presented by these gentlemen has just been published. The commission visited all the leading cities in Europe and America where advanced methods in psychiatry are in vogue. In Berlin the work of Dr. Ziehen was carefully studied. There the hospital plan with two hundred and thirty beds is faithfully observed. There is a day nurse for every four or five patients, and a night nurse for every six. A cheerful demeanor was found in all the wards, with abundance of light and air. The wards were of the decidedly hospital plan and formed a marked contrast to the wards ordinarily found in asylums. Ziehen's clinic is really a sifting department, where the patients are retained as long as there is any apparent hope of cure, or so long as they are required for teaching purposes or clinical study. Those that are found hopelessly insane are at once sent on to the asylum, where careful custodial care is provided. At this clinic much attention is paid to baths, electricity, and hygienic measures. A well-equipped laboratory, with other facilities for study, affords the students of mental diseases excellent privileges. The report describes at length the visits of the commission to Munich and Giessen. At the former place was found the highest development of methods for the early treatment of insanity. Munich, the report says, is fortunate in having such great men as Professor Kraepelin and Professor Altzheimer associated in the management of its clinic. The labors of these men and their coworkers have enriched psychiatric science in a remarkable way and have elucidated many of the intricate problems that have arisen in the inauguration of the advances sought for in their work. The Munich clinic is a plain building in the shape of a large horseshoe. Here every facility was found for the care of the insane. The airy wards, thoroughly equipped laboratory, and well-arranged diet kitchens are specially referred to. Patients are kept in groups. The single room is done away with. Dr. Kraepelin does not believe in isolating patients. There are no "raving cells" at Munich. Every attention is paid to hygiene and the value of open-air treatment. Hydrotherapy is regarded as the *sine qua non* in treatment. The bathrooms were found most interesting, and the continuous baths are a prominent feature. Patients have frequently to remain in these baths for days or even weeks at a time, and it was noted how cheerful and bright even a bathroom can be made by careful attention to details. Every form of the modern douche apparatus was to be found. Electricity has been a disappointment in the treatment of mental diseases at Munich, but is used in some of the nervous cases. Nearly two-thirds of the patients are under constant and careful watch; only the convalescents are without night supervision. Twenty beds are reserved for the study of cases of unusual interest. Some of these, at the time of the visit of the commission, were occupied by cases of juvenile general paresis, a disease rarely seen in America. By this plan the patients,

likely to afford opportunity for much medical observation, are always available. When it is remembered that the staff of physicians is very large and that each case is looked into most carefully by the director and the assistants detailed to study it, and that each case is considered by the staff at one of the daily conferences, it can easily be understood that the individual patient is not lost sight of, but on the contrary receives every attention possible. Those who have been accustomed to the very general and perfunctory methods of care and examination, so commonly used in large asylums, are somewhat surprised at the elaborate details insisted on at Munich. The results fully testify the care and attention given to each individual case. Reactions of all kinds, word associations, memory, emotion, attention, fatigue, and a hundred other problems are attacked in original ways and results carefully preserved. There is a department for comparative study, where observations are made on monkeys, sheep, and rabbits. The experiments with the secretions of glands, sera, etc., are carried on under ideal conditions. There are rooms for psychic time measurement and for measurement of mental effort. Another room is reserved for the ergograph, which contains the writing scales, the apparatus for measuring involuntary and reflex movements, for the observation of the influence of mental processes on the pupils of the eyes, respiration, heart and pulse beat, etc. A sleeping room is specially arranged for the measurement of the depth of sleep. Scientific psychiatry was found by the commission to be more highly developed and its value better demonstrated at Munich than in any other of the many places visited. The report concludes with a recommendation that a psychiatric clinic be established at Toronto in affiliation with but separate from the new General Hospital in connection with the Provincial University. The Ontario Government has evidently given careful consideration to the report and the result has been just announced. The plans have been ordered and provision made for an institution with an equipment that will be modern in every respect. Ontario is likely to have a psychiatric clinic that will afford great advantages to the patients and at the same time enable medical students to acquire a knowledge of mental phenomena that must prove of the highest value. The action of the Ontario Government makes it probable that this province is to be the first in America to have an institution modeled after that of Kraepelin at Munich.

Progress of Medical Science.

New York Medical Journal, May 9, 1908.

A Clinical Study of General Anesthesia.—A. W. Blain, Jr., discusses the various agents used for general anesthesia and the methods of administering them. His general conclusions follow: (1) Chloroform is a dangerous drug, and should be totally eliminated from the armamentarium of the surgeon. (2) The so-called "morphine-hyoscine anesthesia" is unscientific and dangerous. (3) The comparative safety of ether and chloroform cannot be based on our present statistics, but one point is certain: chloroform is always dangerous, while ether given with a comparative amount of skill, is absolutely safe. (4) Nitrous oxide as a general anesthetic is occasionally of value, but its use is extremely limited, as good results can be obtained in these cases where gas is used by ether, if the latter is given with the same amount of skill as is necessary in giving the gas. (5) The anesthetist should pay more attention to his patient, and the surgeon give more consideration to the duties of the anesthetist. (6) The indications in a surgical operation are for ether, and the counterindications are nil.

The Prevalence of Infections in Childhood.—M. Ostheimer discusses the modes of infantile infection, referring to the ear, heart, gastroenteric tract, etc. Our duty is to prevent these infections as far as possible. As most of the infections are believed to enter the body through the lymphatic tissues of the nasopharynx, the most important thing is to keep the nose and mouth clean. This should be begun in infancy, and kept up regularly and continuously until later life. Nurses and mothers must learn to clean noses, mouths, and throats early and with regularity; and signs of the presence of any abnormality, such as adenoids, should necessitate an immediate visit to the specialist. All cervical enlargements are not by any means tuberculous. All infants should be vaccinated between six weeks and three months of age; and all children should be kept in the open air as much as possible during infancy and childhood. Besides, care must be taken in the preparation of all food for children, to prevent infecting the gastrointestinal tract. If any child should come in contact with an infectious disease, precautions should be taken at once, such as the injection of an immunizing dose of antitoxin in case of diphtheria. And the possibility of treating all infections by the opsonic method seems to offer better results than any one method thus far advanced.

Journal of the American Medical Association, May 9, 1908.

Grocco's Sign.—F. Smithies reports a case which exhibited the unusual findings of a well-marked area of paravertebral dullness in the posterior thorax to the left of the spine, associated with an abdominal encapsulated cystadenoma in no way intimately connected with the diaphragm or neighboring organs. A removal of some of the fluid from the abdominal cyst was accompanied with marked changes in the area of the triangle of dullness, and removal of the tumor promptly caused its disappearance. Just how the symptom was produced can only be conjectured, but Smithies suggests the rather marked upward displacement of the diaphragm, indicated by the position of the heart, liver, and spleen together with the absent Litten sign on both sides in this case, as the possible cause. The disappearance of the dullness to the left of the spine after removal of the tumor, rules out any secondary growths in the mediastinal tissues or the lung, and also speaks against the possibility of an unrecognized pleural effusion.

Psychotherapy.—Beatrice M. Hinkle considers the receptive condition induced by hypnosis a useful aid in many cases in which psychotherapy is employed. There are many patients who are persuadable in the waking state, and for these hypnosis is needless, but there are others who are not, and individual treatment must be used. That most persons are to a greater or less extent suggestible, she thinks requires no argument, but it is also true that persons vary greatly in their degree of suggestibility. She does not accept it as a fact that the Americans are less suggestible than Europeans, and she follows Bernheim and Liebault largely in her methods, also imitating Bramwell in giving the intelligent patient a preliminary explanation of what she expects, the probable sensations they will experience, and the fact that sleep, as generally understood, is not necessary in order to experience the benefit of the treatment. There are two types of patients: those who are afraid they will go to sleep and those who are afraid they will not. The former can generally be satisfied with a few explanations; the latter are more likely to be difficult, as they may have a fixed idea that sleep is essential, an idea which will counteract the physician's suggestions. In a few cases in which reasoning failed she has used hypnotic drugs to reinforce the verbal suggestion, but she advises against this as a rule. Three cases are reported, and she calls attention to the fact that in all three all possible physical means had been tried for a long time without result. One of the cases was of psychasthenia of a strongly obsessive type, another of spasm of the esophagus, and another of simple insomnia. The first two were treated by hypnotic suggestion, and the latter by suggestion without hypnosis, all with success in relieving the symptoms.

Intranasal Drainage of the Frontal Sinus.—E. F. Ingals describes his operation for intranasal drainage of the frontal sinus, which he has found one of the most satisfactory surgical procedures, and illustrates the instruments required. Twenty cases are reported. The operation leaves no scar, does not incapacitate the patient for more than a day or two, can be done under local anesthesia, and is practicable in from 95 to 98 per cent. of chronic cases and in a majority of acute cases, provided the anterior end of the middle turbinate has first been removed, which should be done in practically all cases of frontal sinusitis, suppurating or not, in order to secure free drainage. The use of the fluoroscope and *x*-ray negatives is advised as a matter of safety, taken with the probe in position to show the relation of the nasofrontal duct to surrounding parts. Coexisting suppuration of the antrum and ethmoidal cells also calls for free drainage. Too frequent washing out of the frontal sinus is not advisable, though it may be needed once daily for a time to prevent clogging of the tube with dried secretions. Peroxide of hydrogen is dangerous even with free drainage. Reinfection may follow severe colds in the head, but the suppuration soon ceases because of the permanent free drainage. This is secured, even if a cure is not effected. When improvement does not follow in a few weeks the sinus should be opened externally and cleaned out. Healing is as rapid apparently after the intranasal operation as after any other.

The Colon Bacillus in Water.—D. Rivas holds that the colon bacillus should be regarded as essentially a monotype bacillus and not as a group, and that the irregularities observed in cultures are not due to difficult types of the

organism, but to imperfect technique or to the conditions under which the culture is grown. In seeking for some constant reaction, he found that in each of a number of tests of about 0.25 c.c. of a forty-eight hour culture of various organisms on dextrose bouillon rapidly boiled in about 5 c.c. of a 10 per cent. solution of sodium hydrate, there will appear immediately after boiling a clear yellowish lemon color in the tubes of *B. coli communis;* while in others as indication of the absence of this organism, the solution will be clear, taking on a slight pinkish tinge after five or ten minutes. This reaction he calls Test 1. In another independent observation of cultures, also isolated from water, he found that if about 1 c.c. of a 10 per cent. solution of sodium hydrate and then about 1 c.c. of a 50 per cent. solution of sulphuric acid be added to the cultures, some tubes will remain colorless, while others will take on a purple reddish coloration either at once or within a few minutes. Closer study of this reaction showed this to be positive as soon as a growth was apparent in the medium, even after only four or three hours' incubation at 37° C. in neutral bouillon; and further investigation indicated that this purple coloration with sodium hydrate and sulphuric acid was characteristic of the *B. coli* cultures (Test 2). The appearance of the color reaction on the addition of acid is exactly the reverse of what occurs in Test 1, in which the color is discharged by acid and reserved by alkali. The color in Test 2 is not produced in the presence of sugar. He also finds a differentiating sign between *B. coli* and the microorganisms that closely resemble it, in the saccharolytic action of the latter and its absence in the former. He thinks the following conclusions justified: 1. The saccharolytic group, as its name implies, represents not only one, but different microorganisms found especially in water and characterized by their marked action in splitting dextrose. 2. The constant occurrence of this group in water may throw new light on the vital problems of the bacteriology of water. 3. The *B. coli* must not be confounded with the colon group, which Rivas designates as the saccharolytic group, and should be regarded as a type by itself, and not an indefinite group, as at present. Finally, the *B. coli,* in addition to the recognized characteristics, will be positive to Test 2, and negative to Test 1 and Test 3 (the exhaustion of sugar from a 1 per cent. dextrose bouillon medium after incubation for 48 hours at 37° C.), while the saccharolytic group, resembling in many ways the colon bacillus, will always be negative to Test 2 and positive to Tests 1 and 3.

Cystoscopy.—Bransford Lewis reviews the history of cystoscopy and gives the characteristics of the various types of instruments in use. He points out that neither the direct nor the indirect type can meet all the conditions met with, and while the former is the easiest to use under normal conditions, there are some abnormal ones, as when the ureter orifices are placed below a jutting prostate and out of the field of the direct view lens, where the indirect method is more appropriate. For operative cystoscopy, he finds air dilatation the best, while for cystoscopy and ureteral catheterization, water inflation is preferable, and is also the method used with the universal cystoscope devised by him, which is described and figured. From two years' experience with this instrument, he finds that it amply meets the following needs: (1) Direct, forward view; (2) right angle, lateral, view; (3) retrospective view; (4) double, synchronous catheterization of the ureters by the direct method; (5) the same by the indirect method, and (6), an irrigation feature so satisfactory that it is commonly used instead of a catheter for washing out the bladder preliminary to cystoscopy, and it allows irrigation to be carried on during the working of the operator.

The Lancet, May 2, 1908.

Treatment of Trachomatous Dacryocystitis.—The views of T. H. Butler are illustrated by clinical histories of four cases. He says he has rarely seen a case cured by the use of probes or styles. Such instruments, however delicately used, always injure the delicate mucosa and incurable organic strictures are the result. He prefers daily lavage with the Anel syringe, using normal saline or boric acid, and if any mucoid discharge is present, he leaves a few drops of a five per cent. protargol solution in the sac. In Jerusalem where the author practised for some time he found the disease referred to in the title very common and came to the conclusion that the sacs and canaliculi were also trachomatous. Such sacs are often of enormous size. If pus is present in the sac, it is better to dissect the latter out rather than run the risk of retrobulbar abscess. The sac may extend to the middle of the lower lid. Hemorrhage is apt to be very troublesome, but it can be to a certain extent avoided if it be borne in mind that it usually comes from the upper and nasal aspects of the sac. If the dissection be commenced from below and from the outside the sac can often be defined and freed from its attachments before the nasal side is attacked. If possible the angular vein should be located and the skin incision be made external to it; it should not be carried too high up or the branch which comes from the upper lid will be cut. Later in the operation when the sac has been defined the incision can, if necessary, be extended upwards.

Bromide of Potassium Poisoning.—The patient of A. S. Sparks was a woman of 35 years, in the last month of pregnancy. She suffered from facial neuralgia and was ordered the remedy in question, but on her own responsibility greatly increased the dose specified, consuming four and a half drams in less than twelve hours. When seen on the following day she was in a very drowsy and semi-comatose condition. She could be aroused by speaking loudly to her and answered—apparently without understanding the question—in a hesitating and tremulous manner, but was unable to express herself intelligently on account of aphasia. This was extremely well marked, and but for the history and the absence of other symptoms would have strongly suggested a cerebral lesion. Thus the medicine was referred to as soup, pastry, as cushion, and so on. She seemed conscious that she was using the wrong word and after several repetitions of it would relapse into silence. Left to herself she passed at once into a semi-comatose state. The respirations were deep, regular, and slightly stertorous, but not slower than normal. The pupils were normal in size and reacted well to light and to accommodation. The pulse was 76, quite regular, and of good volume and tension. The fetal heart could be heard quite plainly. The knee jerks were exaggerated, and although the muscular movements were slow and feeble the patient was able to leave her bed without assistance and totter about the room. There was no anesthesia of the skin or mucous membranes and she took food readily and with apparent appetite. These conditions continued without any change for two days. On the third day the aphasia had begun to disappear, and by the end of the fourth day the patient was practically well. She had no recollection of what had happened during the first two days. No treatment was adopted except the administration of five-minim doses of liquor strychninæ every four hours. Three weeks afterwards the patient gave birth to a vigorous male infant, the labor being rapid and uneventful.

Edema Limited to the Arms, Face, and Hands.—The case reported by J. M. Bennion was that of a man of 40 years who presented an edema of the regions named, for which no cause could be assigned. Heart, kidneys, and venous system all appeared normal. Neither temperature nor pulse showed any departure from a normal range. Angioneurotic edema was considered as a possible explanation, but the history and clinical features differed (in the author's judgment) in so many details from the usual descriptions of this disease that he did not feel at liberty to accept this hypothesis. [We are by no means convinced that the angioneurotic theory was not the correct one in this particular case. Too few cases of this affection are as yet on record to enable us to make a hard and fast symptom-complex of it.—Abstr.] In this particular instance mercury and the iodides appeared to be of distinct benefit. It is not stated whether or not the man had syphilis.

Multiple Abscesses of the Skin in a Nursling from Colon Bacilli.—B. Auché says that abscesses of the skin in infants are rarely caused by the colon bacillus. He records a unique case of a new-born infant who had multiple abscesses of the thighs, from the pus of which a pure culture of the colon bacillus was obtained. The infant soiled its clothes and in all probability the germs were derived from the discharges from the bowels, and entered through the unbroken skin. It seems very unlikely that they came by way of the circulation from the bowels.—*Journal de Médecine de Bordeaux.*

Disapproval of Koch's Suggestion.—Koch's proposal for destroying big game in order to exterminate the tsetse fly is being opposed in Germany. There is an association there for the preservation of African game, and a number of its members are experienced travelers and zoologists. Professor Matschie of the Royal Zoological Museum controverts Koch's statements as to the disappearance of the fly where gregarious game is no longer found, and denies that the fly was formerly prevalent all over South Africa. Dr. Sander of the Army Medical Corps, who has traveled over wide tracts where flies are numerous but there is no game, says small animals are just as likely to be intermediaries. He agrees with those who say that the clearance of dense underwood is the best way to deal with the fly.

Society Reports.

THE MEDICAL ASSOCIATION OF THE STATE OF ALABAMA.

Annual Session, Held April 21, 22, 23, and 24, 1908, at Montgomery.

THE PRESIDENT, DR. SAMUEL WALLACE WELCH, OF TALLADEGA, IN THE CHAIR.

THE Association met in the Chamber of the House of Representatives at the Capitol. After prayer by Rev. E. E. Cobb, and addresses of welcome by Dr. Henry B. Wilkinson, on behalf of the Montgomery County Medical and Surgical Society; by Mr. C. P. McIntyre, on behalf of the City; by Hon. B. B. Comer, Governor of the State of Alabama, the President delivered his annual message.

Early Diagnosis of Carcinoma of the Uterus.—Dr. I. L. WATKINS of Montgomery said that while there were many things regarding the etiology and histology of cancer yet unknown, our present knowledge of the disease justified the opinion that in nearly all cases of malignant disease there was a time when it was possible to eradicate it completely. In the study of suspicious cases it was always important to get a very accurate history of the woman's habits and her condition from the time of her early menstruation. The question as to whether or not children had been born, although not conclusive, was important in estimating the value of symptoms. The conditions that would help most in the recognition of this lesion in its earliest stages were some deviations in the menstrual function or other uterine discharges, or a recurrence of a bloody discharge after the menopause. These changes might come in the form of an excess or as an intermenstrual discharge. In a woman beyond the age of thirty these symptoms should always be regarded with suspicion. Carcinoma of the uterus might be classified according to its location as carcinoma of the body or carcinoma of the cervix. Carcinoma of the cervix might be divided into two groups, as those arising on the vaginal portion, and those in the cervical canal. The squamous cell carcinoma of the cervix comprised nearly one-third of all cases of cancer of the uterus. This form was rarely found elsewhere than on the cervix. In a few instances it had been found in the body. The cylindrical-celled carcinoma of the cervical portion was infrequent as compared with the squamous celled, although it might arise from the mucous glands of the cervix, or from the surface epithelium. In cases where the cylindrical epithelium of the cervical canal extended beyond the external os, this would be expected. Carcinoma originating in the cervical canal was the most fatal form of cancer of the uterus, by reason of the greater blood and lymph supply of these parts. Cancer of the body was much less frequent and occurred later in life. Its progress was much slower, and the prognosis in operating on these cases was much more favorable.

Dr. M. B. CAMERON reported a case in which the uterus was enlarged to twice its normal size and the os almost entirely destroyed by the cancerous growth. The woman had no symptoms except pain and a profuse watery discharge.

Dr. JOHN R. HOWELL had never been able to make a diagnosis of cancer of the uterus any too early to operate and save the life of the patient.

The Diagnosis and Medical Treatment of Gastric Ulcer.—Dr. JAMES E. DEDMAN of Birmingham read a paper with this title in which he drew the following conclusions: "1. Gastric ulcer uncomplicated is a strictly medical disease. 2. There are complications which arise, such as hemorrhage, anemia, and persistent vomiting, which are still amenable to medical treatment. 3. As far as the treatment of the ulcer itself is concerned, absolute rest in bed for at least four weeks is imperative, and the Lenhartz diet is the best yet devised, being far superior to any form of rectal nourishment, because it readily affords rest to the stomach and at the same time supplies the patient with a highly nutritive food. 4. Drugs are of little value, so far as healing the ulcer is concerned. 5. Olive oil, on account of its caloric value and property of reducing hyperacidity, is of much value, but should not be given in cases where there is pyloric stenosis, as it retards the evacuation of the stomach contents. 6. The hemoglobin percentage should be carefully watched and some form of iron or arsenic administered to maintain it. 7. A careful dietetic régime should be enforced for practically one year, and no patient should be considered cured unless the cessation of gastric symptoms lasts for at least two years. 8. Uncured ulcers, quasicured ulcers, and even the cicatrices of healed ulcers offer a most inviting habitat for carcinoma later in life. 9. Persistent, unrelieved hemorrhage, painful perigastric adhesions, hyperplastic infiltrations resulting in pyloric stenosis, and perforations are phases of gastric ulcer that unquestionably belong to surgery."

The Surgical Treatment of Gastric and Duodenal Ulcers.—Dr. GASTON TORRANCE of Birmingham, after speaking of the frequency of ulcer, and discussing the etiology, pathology, symptoms, and treatment, reported a perforating gastric ulcer which he closed by suture, no-loop gastroenterostomy with recovery of the patient. He also reported a case of rupture of the gall-bladder, with severe hemorrhage from gastric ulcer. In this case there was also an obliterating appendicitis. Cholecystectomy was done, as well as Mayo's no-loop gastroenterostomy, resecting the ligament of Treitz, followed by appendectomy and recovery of the patient.

Dr. CHAS. W. STILES of Washington, D. C., referred to the recent work of Vineberg in the Pasteur Institute, in which it was shown that various gastric and intestinal parasites might act not only in wounding the intestine, but in carrying infective bacteria into the wounds. This work shows that we could have ulcers arising directly as the result of parasitic infection. In hookworm disease, a slight pressure in the epigastric region gave rise to almost instant resistance on the part of the patient. This pain could be followed down towards the right, but disappeared suddenly as the hand was passed towards the left.

Dr. DYER F. TALLEY of Birmingham said that a great many lives had been saved in recent years as a result of the technique developed in the treatment of stomach troubles surgically. Medical treatment should not be too long continued, when it seemed to do no good, especially in cases in which there were any urgent symptoms, such as the vomiting of blood or evidence of stenosis at the pylorus. Cases of gastric hemorrhage could be relieved by gastroenterostomy.

Dr. LEWIS C. MORRIS of Birmingham thought that gastric ulcer primarily in all cases was a medical condition, and became surgical usually only when there were complications, such as perforation, hemorrhage, stenosis, etc. He related an interesting case in which he operated two years ago for hour-glass contraction. In this case there was almost complete obstruction of the stomach. He did the exact analogue of Finney's pyloroplasty upon the hour-glass contraction. In recurring hemorrhages from gastric ulcer, drainage was justifiable.

Malaria in Children.—Drs. B. B. SIMMS and H. B. WARWICK of Talladega presented a joint paper on this subject in which they said that from their observations many persons carried in their blood the malarial parasite for months without active symptoms of malaria, for they had observed the plasmodia from time to time for a period of from five to six months during which no paroxysm occurred. The probable reason for the absence of malarial symptoms was that the number of parasites in the body was too small, since it was estimated that there must be from 200 to 300 millions in the human system to produce the paroxysm. The intervention of some other disease would cause the parasite to increase, thereby giving rise to malarial symptoms.

Dr. W. H. Sanders of Montgomery reported a case which he diagnosed as yellow fever, but which was doubted by several physicians because the woman's blood contained the malarial organism. His diagnosis of yellow fever, however, was subsequently verified by autopsy.

Dr. Chas. W. Stiles said that when the malarial parasites were found in the blood of patients for a long time, it was usually the female parasite that was found. The sexual parasite had passed through its evolution to the point where it could not reproduce any further, and it then evolved into the male and female forms. The female form of parasite contained a great deal of nutrient material. The male parasite was composed chiefly of nucleus, with very little nutrient material. Accordingly, the male parasite died out in the blood, but the female might last for a long time.

Dr. John P. Stewart spoke of the difficulty of differentiating the form of parasite found in the blood.

Pyuria in Women.—Dr. Henry D. Furniss of New York, in speaking of pyuria, said not all cases of purulent urine should be included. Only those in which pus was from the urinary tract were considered. Whenever pus was found in the urine, the first effort should be to locate its origin and determine the etiological factor. The majority of the inflammatory disorders of the genitourinary system recovered spontaneously after the removal of the cause. In the acute cases there was not much difficulty in locating the origin of the pus, for the local symptoms were sufficiently intense to point to the source of the trouble. When there was pus in the bladder urine, if the bladder was catheterized and carefully washed, and if a second specimen obtained by means of a catheter an hour later contained the same amount of pus as the first, the inference was clear that the pus was derived from a source outside of the bladder. With the aid of the cystoscope, one could determine the nature, the extent, and often the cause of the lesion with which he had to deal.

The Cause and Treatment of Summer Diarrhea of Infants.—Dr. W. W. Harper of Selma said that all bottle-fed babies should be put on pasteurized or sterilized fresh cow's milk, with a fat percentage at or below 3½. Should curds appear in the stools, we should use skim milk or buttermilk, returning as soon as possible to whole milk. Since living lactic acid bacilli were now procurable in tablet form, the pasteurized milk should be sown with them during the summer months, as these bacilli inhibited the germination of the pathogenic spores which were not killed by sterilizing. They kept the intestinal tract acid, which was an unhealthy media for all pathogenic germs. These lactic bacilli also reinforced the normal intestinal flora. Their good effect was felt for some time after their ingestion. The nurse and mother should be told to discontinue milk with the first loose, green, or foul stool, and to send for the doctor. One should give a dose of castor oil, or small doses of calomel, if the stomach was irritable. Boiled water should be given for the first twenty-four hours and rice or barley water for the second twenty-four. During the starvation period tablets of lactic bacilli should be administered. At the end of forty-eight to seventy-two hours, one should give buttermilk which had been pasteurized and then inoculated with lactic bacilli.

Treatment of Deep-Seated Gonorrheal Infections with Gonococcic Vaccines.—Dr. C. W. Shropshire of Birmingham reported three cases which he had treated by these vaccines, one of which was complicated with gonorrheal rheumatism and epididymitis. He did not use any internal medication in this case, neither was there any local treatment given, the vaccine being the only treatment. In the other cases he used locally irrigation of one per cent. solution of carbolic acid which he found very beneficial in keeping the urethra clean. There was no antiseptic or astringent used locally. He did not give any internal medication. He had found that the constipation which complicated the cases had been entirely relieved. He had never seen any bad effects from the injection of the vaccine with the exception of a slight pain at the site of the injection, due to the pressure of the fluid in the tissues. He had given it in doses of from 25 million killed bacteria to as much as 500 million killed bacteria. When these large doses were given, they should be made in several injections at the same time, and one should not try to force over two c.c. of vaccine, or 100 million killed bacteria in one injection. In two cases he was unable to find the gonococci in the discharge or shreds before he gave the vaccine, but after giving the vaccine he found the gonococci present, proving that if the gonococci were buried in the deeper tissues the vaccine would cause them to be eliminated. In discharging so-called well cases, it would be a good idea to give them a course of treatment with vaccine to see what reaction would be produced. He believed that we had a most valuable agent in these vaccines, but as yet his work had been too limited to give any positive expression on it.

Surgical Treatment of Exophthalmic Goiter.—Dr. Dyer F. Talley of Birmingham said there had been much discussion recently as to the best methods of treating exophthalmic goiter, and the internist had come to admit that in many cases surgical treatment was not only the best, but the only treatment which offered any hope of permanent relief. Good and scientific work was being done by Rogers and Beebe in obtaining a cytotoxic serum which had been used with benefit, but this serum was difficult to prepare and might not be of uniform strength always. Benefit had been derived from the use of the milk and blood from thyroidectomized animals, and many drugs had been recommended as useful, but the improvement due to these remedies was often temporary and lasted only during treatment. While the author's experience had not embraced many cases, the results in the few he had treated surgically had been so uniformly good that he regarded the operation as being attended with as much success and satisfaction as the removal of a diseased appendix. His results were 100 per cent. both as to recoveries and the relief of symptoms for which the operation was done. He attributed this success to the fact that the cases of exophthalmic goiter were seen early.

Acute Intestinal Obstruction.—Dr. Edward W. Peterson of New York discussed the treatment of this affection with especial reference to intussusception, and reported five cases in which he had operated, three of which were successful, and two fatal. He believed that with a better knowledge of the mechanics and with a more thorough understanding of the pathology of this disease, would come a realization of the futility in most instances of the palliative measures. The keynote of success would bear reiteration, namely, early diagnosis and prompt radical treatment.

Remarks on Psychotherapy.—Dr. Cabot Lull of Birmingham referred to some of the qualifications desirable in practitioners who aspire to succeed with psychotherapy, and among them he mentioned (1) a diagnostic ability sufficient to enable one to exclude all organic conditions and to make a reasonably positive diagnosis of nervousness. (2) A perfectly honest, fearless, and confident attitude toward the patient. (3) Some knowledge of human nature, a reasonable sympathy for suffering and mental instability, and lastly, tact. Special training in psychology was of great advantage, and this was within reach of nearly every general practitioner, in a country where schools and libraries were plentiful. This would enable one to obtain possession of certain valuable data in regard to the mental status of his patients. Whatever method was adopted, the great underlying principle was the same, namely, the application of psychic remedies to psychic diseases.

Mouth-Breathing.—Dr. R. C. Young of Anniston discussed this condition as a factor in producing deformities of the dental arches.

Dr. William Groce Harrison of Birmingham discussed

some of the causes and evils of mouth-breathing. In children adenoid vegetations in the nasopharynx were responsible for a large majority of the mouth-breathers, and no examination was so satisfactory as palpation with the forefinger rapidly passed back in the throat to one side, and then insinuated behind the soft palate. He laid stress on the etiological relationship between adenoids and middle-ear disease, saying they might produce only a catarrhal condition of the Eustachian tube or perchance a real occlusion of its inner orifice, and here one saw impaired hearing. Such a child was often scolded and rebuked for inattention, when in reality the ears were at fault.

Clinical Migraine Due to Unusual Refractive Errors.—Dr. Kenneth Bradford of Birmingham said that the prime object of his paper was to bring before the Association the important connection between organic defects in the eye and that complex functional disorder known as migraine. Continuous relief, for a period of seven months, from attacks of migraine of increasing frequency of a most aggravated type had, in the author's own case, followed immediately upon the detection and correction of a rather unusual refractive error. This error was detailed at length and the symptoms caused by it described.

Epidemic of Jaundice.—Dr. D. P. Dixon of Talladega described an epidemic of jaundice which occurred in Talladega during the summer of 1907. Of the two hundred cases reported, only twenty-five were in children, and eight of these were infants. The blood of the latter was examined and found to contain the malarial plasmodium. Thirty of the cases reported were among women; the other 145 occurred among men of previously good health. Fifty of the cases were among negroes. There were probably many more cases in this race that passed unnoticed. Almost all of the cases collected were among the well-fed, well-clothed, and well-housed classes. The cases among children were, with the exception of the babies, entirely among boys. Not a single girl was reported as having jaundice. These boys were about ten to twelve years of age, well developed and previously healthy lads. They were not so severely taxed as the adults in either the length of the attack or its intensity, although in the beginning the febrile stage was almost the same. The men affected continued at their usual occupations after the first two, three, or four days, or after the febrile stage had passed. There were a few cases during the winter months which were more severe and lasted for a longer time, because most of these patients were indoors most of the time on account of the very severe weather, and did not get sufficient fresh air and sunshine. In looking up the causes given by writers on this subject, the author found that very few mentioned malaria as the predisposing cause. Nothnagel put the different causes into three classes: (1) Atmospheric, telluric, or climatic causes; (2) Dietetic influences; (3) Infectious causes. The infectious class, according to the author's theory, played the leading part in the causation of this epidemic. The majority of the cases of jaundice appeared gradually with headache, malaise, drowsiness, abdominal pain, and cramps in the legs, and subsequently usually vomiting; moderate temperature (although the temperature in some went as high as 104°), chills and chilliness. Jaundice came on several days after the appearance of the first symptoms. Generally, by this time, the temperature was normal, and when there was no complication it did not rise again. In some the temperature at this time became subnormal and remained so for some time. The patients usually had a very slow pulse, with putty-colored stools, highly colored urine and sweats, and other symptoms seen in catarrhal jaundice. These cases usually lasted from two to eight weeks. There were very few complications. Two cases were taken with biliary colic, and after the acute symptoms had subsided, became jaundiced. Another was the case of a boy with pneumonia. In another a woman just before confinement became very much jaundiced. The child was still-born, and the mother died in a few days.

Symposium on Tuberculosis.—One evening was set aside for a discussion on tuberculosis. This meeting was well attended by the laity. Papers were read as follows: "A Serious Condition in Alabama and how to Meet it," by Dr. Glenn Andrews of Montgomery; "Social Aspects of the Tuberculosis Problem," by Dr. S. A. Knopf of New York; "The Layman's Duty in the Fight against Tuberculosis," by Hon. H. T. Reese of Selma; "The Duty of the Press in the Fight against Tuberculosis," by Major W. W. Screws of Montgomery.

Ethics of the Profession.—Dr. W. M. Wilkerson of Montgomery delivered the "Monitor's Address." He spoke on the Ethics of the Profession and urged both the public and the profession to strive for a better understanding of each other. He appealed to the people to aid the medical profession in all measures looking toward the improvement of mankind; to help them with their intelligence and to assist them with their means in all public enterprises for the physical betterment of the human race. To the members of the profession he said: "Give of your time and experience and training all that may be required for the still further uplifting and ennobling of our profession and for the good of our fellow-beings. Let no task be too difficult, no ideal so high that you do not strive to attain it. Thus let us press onward—doctors and people—hand in hand, toward that goal where sickness and suffering are unknown."

The Annual Oration.—Dr. Wellington P. McAdory of Birmingham delivered this address. Among other things he said that medicine to-day was nearly an exact science. This scientific position had not been reached in a year, a decade, or a century, but, founded upon nature, it had gradually developed, and each step in this development had been marked by the saving to the world of countless lives and suffering. The practice of this science was the art of handling disease, and these artists were ordinarily called practitioners of medicine. He reviewed at length, and portrayed in glowing terms the great progress that had been made in medicine and surgery in the last decade or so.

Officers.—*President*, Dr. B. L. Wyman, Birmingham; *Vice-President*, Dr. R. J. Reddens, Vernon; *Secretary*, Dr. J. N. Baker, Montgomery, reelected; *Treasurer*, Dr. Henry G. Perry, Greensboro, reelected.

Birmingham was selected as the place for holding the next annual meeting.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON SURGERY.

Stated Meeting, Held April 3, 1908.

Dr. Charles H. Peck in the Chair.

Hernia of the Lung.—Dr. Edward Adams presented a patient with hernia of the lung, an unusually interesting condition because of its rarity. The first case of this nature was reported in 1499; from that date up to 1906 but 48 cases had been recorded. These 48 cases were classified as congenital (10 cases), spontaneous (8 cases), and traumatic (30 cases). During the Civil War there were recorded about 20,000 injuries to the chest wall, and among these were found but five cases of traumatic hernia of the lung. During the Russo-Japanese War not one case was reported. The patient Dr. Adams presented was a man, 22 years old, an iron-worker. His previous history was practically negative, having never been seriously ill until his present trouble. Two years ago, while at work in Buenos Aires as an iron-worker, when lifting a heavy piece of iron, he felt something give and soon noticed a bulging in the upper intercostal region. The day following he noticed, when bending forward, that he had severe pain in this region. He consulted a physician, but got no relief. The pain did not disappear for a period of eighteen months when he had the swelling which he now presented. Six months ago he noticed that the pain was

located somewhat lower down. He came under Dr. Adams' observation one month ago. On inspection nothing was to be seen except a slight bulging in the second and third intercostal spaces, near the median line on the right side. When he bent forward the swelling became more marked than when he was in the erect position. Upon palpation the swelling was found to be soft and elastic to the touch. It was not adherent to the skin. On percussion it was tympanitic. On auscultation there was a slight exaggeration of the breath sounds and the vocal fremitus was increased. No râles were to be heard except posteriorly, and these were due to a pleurisy. The differential diagnosis was to be made from aneurysm, empyema, abscess of the lung, angioma, lipoma, cyst, cold abscess, etc. When one pressed deeply over the swelling, it elicited some pain. The *x*-ray picture showed nothing. He aspirated the swelling but got absolutely nothing. The treatment was a pad applied over the hernia; this was retained in place and if no improvement followed in time, operation would be resorted to, incising directly over the swelling and suturing the muscles down over the opening with silver wire.

Dr. William Henry Luckett did not believe this to be a case of hernia of the lung, for it did not feel to him what his conception of the feel of a lung would be in and out under the finger through the opening. Again the man's chest was not one that showed a normal muscular development; what development there was of the chest was due to his work. He had sloping shoulders and a narrow chest. The man could not produce this tumefaction while in the standing position; if this was a hernia he could produce it in whatever position he assumed. It seemed more like the swelling contained fluid, forced out by the expansion of the lung behind it. It did not appear, or come out, as one would expect a lung. It did not crepitate under the finger or on auscultation. He could not understand why, if it was a hernia, the doctor had gotten nothing when he aspirated the swelling; he certainly should have gotten air. The case impressed him as being some peculiar sacculation possibly containing fluid. There was a small opening, and a sac inside as well as outside the chest wall. It had a wallet-purse shape, and gave no fluctuation whatever.

Dr. H. A. Haubold agreed with Dr. Luckett that this was not a hernia of the lung. It was too near the median line. If the patient made a sudden exertion, or took a deep inspiration, it would drive the lung towards the diaphragm where there was room for it to go. He thought it might be a branchiogenetic cyst.

Dr. A. V. Moschcowitz believed it was a hernia of the lung. He had had occasion to examine it carefully some time ago and believed in the diagnosis made. He explained it on the ground of the pathological or surgical anatomy of the lung. The protrusion came out at a point where the artery perforated. He had seen one other case of hernia of the lung of traumatic origin and that man presented similar symptoms.

Dr. Willy Meyer saw this patient several weeks ago and he believed in Dr. Adams' diagnosis. The man got his hernia by lifting a heavy weight. The percussion sounds belonged to the lung, and were easily made out. With increased intrathoracic pressure there was an increase in the size of the hernia.

Dr. Charles A. Elsberg called attention to the fact that when the patient inspired the skin over the tumor sank in, and when he expired it bulged out. He thought it was probably a hernia of the pleura that contained no lung, the sac being formed by the parietal pleura.

Dr. Moschocowitz said that assuming that Dr. Elsberg was correct, the hernial sac being composed of pleura, what was in it?

Dr. Elsberg replied that it might contain some fluid from the pleura.

Dr. Adams said that the patient he presented, although he had been an iron-worker, had not been able to work during the past year and one could not expect to find well developed muscles of the chest. With regard to its being a cyst, symptoms did not point to such a formation. The physical signs pointed solely to the presence of lung, and nothing else but lung.

Perforated Gastric Ulcer; Gastroenterostomy.—Dr. William C. Lusk presented a patient who came to Bellevue Hospital February 19. For the previous two weeks he had been having pain after eating, the pain lasting fifteen minutes and then disappearing. On February 19, about 9 A.M., he was seized with sudden pain in the abdomen, which was followed by vomiting. He vomited four times. Dr. Lusk saw him about 5 P.M. and he found the abdomen rigid and tender, particularly over the region of the appendix, and to a less degree over the pit of the stomach. His pulse was 90, temperature 101.8°, and respirations were 36. The number of leucocytes was 17,000, and the polymorphonuclears 90 per cent. An operation was advised but at first refused. The pain increased a great deal and then the man consented to operation. Fourteen hours following the onset of the attack operation was performed. The pulse at that time was 86. The incision was made over the site of the appendix, and a large quantity of pus gushed out. There was probably as much as a pint and a half altogether in the peritoneal cavity. The pelvis was full of pus, and the lower coils of the small intestines beneath the omentum were bathed in pus. A considerable quantity of pus came down from above in front of the omentum. The appendix was not found to be diseased and was left intact. A second incision was then made above and a small perforation about 1 cm. in diameter was revealed in the anterior wall of the stomach at its upper portion near the pylorus. There were adhesions around the gall-bladder which was adherent over the entire front of the pylorus. The perforation was situated close to the line of adhesion of the stomach to the gall-bladder. The peripheral induration was about one-half an inch. The perforation was closed with three rows of chromic sutures uniting the gall-bladder to the stomach and finally drawing a piece of fat from above and one from below, together over the line of union. A posterior gastroenterostomy was done by suture, leaving no slack in the loop of jejunum. No irrigation was employed. There was little sponging, and the bulk of the pus was taken up by large gauze pads tucked down into the pelvis. A drain was introduced through each wound, one into the pelvis, the other down to the site of the ulcer. When the patient was next seen, eight hours after the operation, he was complacently paring his finger nails. The temperature dropped promptly to normal and the patient made an uninterrupted recovery. Dr. Lusk then called the attention of the Section to the dog experiments by Fibich who, after producing gastric ulcers artificially by ligating the arterial supply to a certain area, denuded the part of its mucous membrane and cauterized it with nitric acid; he found that with no gastroenterostomy such an ulcer remained unhealed for as long a period as three weeks; but when a gastroenterostomy was performed at various intervals of time following the production of the ulcer, healing of the ulcer in each instance occurred within three or four days. The pulse in the case reported was no indication of the patient's real condition. The diagnosis was practically made on the physical signs together with corroborative blood findings.

A Series of Cases Illustrating the Result of Bier's Hyperemic Treatment.—Dr. Willy Meyer presented a series of cases. He said he was interested in Bier's hyperemic treatment and believed it to be the best way to achieve certain results. He thought it was better to show patients than to talk about results of this method of treatment. As was well known Bier started his artificial hyperemia in the treatment of surgical tuberculosis. He had read that pathologists had seen that patients with

chronic hyperemia of the lungs due to valvular heart disease, would not be stricken with tuberculosis. If tuberculosis was present, and disease of the heart which produced the hyperemia had appeared later, one would find scars at the apices. On the other hand, a patient with stenosis of the pulmonary artery was apt to be stricken with tuberculosis. On the basis of this, Bier started his surgical investigations in 1892 and he and his followers had since shown results. It was now known that artificial hyperemia was a powerful agent, rich in therapeutic resources. Formerly physicians worked with remedies on a chemical basis; now, in addition, with one on a physical one: Bier's footsteps were now followed here as well as abroad. The profession was now only beginning to understand its value. He felt sure that as physicians knew more and more about it they would appreciate its value more and more. The point in the Bier hyperemic treatment was, instead of fighting the symptoms of inflammation, to increase them by means of an increased amount of blood. To accomplish this they applied to the extremities an elastic bandage, to the head an elastic band, to the shoulders or testicles an elastic tube, etc. Over other inflamed regions of the body a glass apparatus was applied, which proved as useful as the elastic bands.

Eleven patients were presented by Dr. Meyer. The first was a man with a carbuncle of the neck. The patient came to the hospital twelve days after the onset complaining of pain in the upper forearm, but was discharged because his symptoms were not marked. After a few days there appeared a pronounced edema, tenderness, and pain about the caput radii, evidently a deep seated metastatic phlegmon or periostitis. The patient was readmitted and Dr. Meyer applied Bier's treatment, increasing the amount of blood to the part. This was followed by an entire disappearance of the inflammatory symptoms. In from three to five days the temperature became normal. Whereas in the beginning of the treatment there was great tenderness, and inability to pronate or supinate the forearm, he now had full motion and was able to work. The treatment was applied eleven out of twelve hours. He had simply been cured by means of the Bier treatment. The second patient presented was a young woman with an abscess of the neck, due to subacute inflammation of the lymphatic glands posteriorly. She came under his care only four days ago with a large abscess over the occiput, filling the posterior space behind the sternocleidomastoid muscle. A very small incision was made and the Bier suction treatment applied. This abscess under old methods of treatment would have taken four or five weeks to cure; to-day it was discharging only serous fluid under suction. It was a streptococcus infection. The third patient he presented was a woman with a mastitis, not a very bad one such as a phlegmon of the breast. All would agree that these patients with mastitis, before the incision was made, passed sleepless nights, and they knew how they had been fighting the advice of midwives who wanted to apply hot poultices, when the physician wanted to apply ice-bags. The application of the heat was better, because more blood was carried to the breast. According to the old treatment of mastitis, the incisions were large and radiating, and, in many instances, the function of the breast and its shape were destroyed. After Bier's suction treatment these patients passed restful nights, required only a small incision, and had little pain. This patient was now almost cured. The fourth patient presented was a man with an injury to the sheath of the flexor tendon of the thumb. This had been treated for twelve days before he came to the hospital, having had many incisions made. There was then a tremendous suppuration in the large synovial sac, involving the ring and small fingers. He did not make *one* long incision but many short ones, preserving the transverse ligaments of the fingers. In eight days the temperature fell to normal. So far no pieces of tendon had come away. Whenever a new abscess appeared it was at once incised. This patient, under the old methods of treatment, would have had his fingers in volar flexion, contracted, and to overcome this would have required many weeks. This man would probably get a good and useful hand. To produce absorption of the edema, so often presented after cicatrization, nothing was better than hot air in producing arterial hyperemia. The fifth patient he presented was a colleague who received a compound dislocation of the thumb at the distal joint. Twelve days later there was much joint suppuration and periostitis of both phalanges. No drainage of the joint was made. He enlarged the compound wound and cut down straight through to the bone, slitting the periosteum of both phalanges, and placed him on Bier's treatment, with the result that the patient now had a useful thumb. He knew of no other treatment that could have accomplished such a result. The treatment was applied ten out of twelve hours. The functional result was excellent. The sixth patient presented was a boy who had a sinus of the inferior maxilla due to chronic osteomyelitis, which discharged pus. His teeth had been extracted. It was proposed to chisel away the bone. The mother however was opposed to any operative interference. Under the application of the Bier suction treatment, faithfully done by the mother at her home, the fistula, which led through the bone into the mouth, had entirely closed. The seventh patient presented was a boy who had sustained a fracture at the base of the skull from falling down stairs. He had all the symptoms of fracture of the base of the skull. Six hours afterwards he was admitted to the hospital and the Bier method of treatment applied with the neck band. He made a rapid recovery; Dr. Meyer had never seen such rapid progress made in such a case as was made under this treatment which prevented the occurrence of meningitis. Of course, such observation needed further corroboration. The eighth patient presented was a woman, 63 years old. Two years ago she had a severe pneumonia with endocarditis. Dr. Meyer was called to see her when she had an acute beginning gangrene of the arm, due to an embolus of the brachial artery. These were very serious troubles. The hot-air treatment was employed. Increasing the temperature of the part in this way, causing an arterial hyperemia, did a great deal of good. She did not lose even a piece of skin and the collateral circulation appeared quickly. The ninth patient presented was a man who had had an ankylosed wrist of gonorrheal origin. Dr. Meyer saw the patient some time after the gonorrheal invasion of the wrist joint; the joint was stiff and painful. Surgeons, who did not use hyperemic treatment, would have ordered a splint and ice-bag, later baths, massage, etc. In this case an elastic bandage was applied around the arm eleven out of twelve hours, and the patient now had a movable joint and, if the treatment was continued, he would get still better function of the hand than he now had. The tenth patient presented, 46 years old, had had tuberculosis of the wrist, with all the pathognomonic symptoms. The result of excision in these older patients was not good, so far as function was concerned. This was a feeble man and he thought it best to apply the elastic bandage. (This was in the fall of 1903.) A cold abscess appeared later, which was aspirated, and the cavity injected with iodoform emulsion. Bier's treatment had been used by the man only four months steadily. Nevertheless the tuberculosis of the wrist was healed. This was an extraordinary case; cures of this kind usually took much longer, about one year. The eleventh patient presented had suppurating tuberculosis of the second testicle after castration on the other side. He was much better after the application of the Bier method of treatment. Dr. Meyer said doctors had no right promptly to advise castration for a tuberculous epididymitis on one side, if the other testicle was removed. Bier's treatment should be applied before removing a testicle was thought of.

Dr. James Morley Hitzrot said that he had employed this method at the dispensary for two and a half years, first employing it in tuberculous cases and since in the acute infections. He had usually gotten bad results in streptococcic infections of the superficial variety.

Dr. Lyle had been very successful with this treatment after using it for five years in the hospital. What Hunter said to Jenner in regard to vaccination could be applied here, "Do not think, but try."

Dr. Meyer believed that longer cuts should be made in infections of the tendinous sheaths, in osteomyelitis, etc., and then the Bier treatment applied. The incisions had to take care of the pus, artificial hyperemia of the inflammation. This was a new and powerful agent in therapeutics on a physical basis. Dr. Meyer then demonstrated the Kuhn mask for producing artificial hyperemia of the lungs.

Pneumothorax and Posture; the Importance of the Abdominal Posture in Operations on the Pleura and Lungs.—Dr. Charles A. Elsberg read this paper. (See page 846.)

Arthritis Deformans of the Hip; a Preliminary Report of a New Operation.—Dr. Fred H. Albee read this paper. He said that arthritis deformans of the hip was a chronic joint disease, characterized by a slow and gradual onset, absence of fever, local pain, muscular spasm, wasting, stiffness, disability, and deformity, but never presenting any tendency to suppuration. It had been known by many names, the most common of which was coxitis senilis, which implied that it was a disease of old age only, therefore, misleading and not appropriate. This affection had been ascribed to gout or rheumatism, to exposure to traumatism, but the writer was convinced that old age played a small part in the etiology. Blodgett reported in 1903 ten cases in which the onset of the disease occurred, in two under 30 years of age, in two between 30 and 40, in three between 40 and 50, and in three between 50 and 60. The point of origin of arthritis deformans, whether in the synovial membrane, the cartilage or the bone, was still a disputed point, although recent authorities were inclined to consider it among the arthropathies of spinal-cord origin similar to the Charcot joint associated with syringomelia and tabes. The joint fluid was increased in the early stages, but diminished later. Changes in the cartilage were noted early, the cells multiplied, and the hyaline substance degenerated, rendering the cartilage friable. It took on a yellowish appearance and the articular surfaces became thinned in the center and finally disappeared entirely. The head of the bone thus laid bare became smooth, polished, and eburnated. Marginal osteophytes appeared, sometimes perforated the synovial membrane, became pedunculated or even detached, and appeared as loose bodies in the joint. The acetabulum was deepened and the motions of the hip were much limited and tended toward that of a cylindrical joint on account of its anatomical change. The head wore away more and more and the marginal outgrowths progressed toward the trochanter. The neck hypertrophied and might bend, thus becoming more at a right angle with the shaft. There was a consequent shortening of the leg. As the adductors and flexors of the thigh were not only more powerful than their antagonists, the abductors and extensors, but exerted their force at a better mechanical advantage, there was only one result, if not prevented by treatment, and that was increasing adduction and flexion with permanent contracture or ankylosis. Dr. Albee then considered the symptoms of arthritis deformans of the hip, and the treatment, local and general, that had been employed. He then detailed a case of interest, a man, 59 years old, who had arthritis deformans of the right hip. The brace treatment was recommended and explained to the patient, but it was refused on the ground that it was too long and uncertain for a working man. Eleven months ago the patient applied to him with the inquiry if something could not be done for him. He was a policeman. Three years ago he first began to notice pain and stiffness in the right thigh and hip. Twenty-two months ago he was again examined by a physician who told him his right hip was dislocated and the right leg was shorter by two inches than the left. The symptoms became so severe that he submitted to operation, the nature of which could not be ascertained. Symptoms of lameness, stiffness, and pain had continued unabated ever since. The physical examination showed a powerfully built man, weighing 185 pounds, pale and worn, walking with a marked limp. The leg was much atrophied and markedly flexed and adducted, and motion was entirely absent except for slight flexion. Any attempts at passive motion resulted in pain. There was some muscular spasm. A skiagraph showed the head of the femur much worn away and flattened, with many bony outgrowths about the rim of the acetabulum. Because of the disintegration of the joint, the marked adduction and flexion with firm contractures, the progressive bony ankylosis, with the limb in faulty position, in so large and powerful a man, it seemed best to aim for immediate firm ankylosis, with the limb in a position of slight overcorrection of the deformity to compensate for the existing practical shortening. The hip joint was reached by an anterior incision five inches long, through skin and subcutaneous tissues, starting just below and inside the anterior superior spine of the ilium and extending downward along the inner border of the sartorius muscle which was retracted outward. The muscles and deep structures were separated by blunt dissection and the iliacus and rectus femoris were retracted inward. A large part of the ring of oestophytes about the rim of the acetabulum were turned inward with the soft tissues adherent, because it was thought wise to leave as many of them as feasible on acount of their bone-formation possibilities. With the head of the bone in situ about one-half of its upper hemisphere was removed through a plane at right angles to the long axis of the shaft of the femur. The acetabulum was then transformed into a flat-surfaced roof, against which the fresh surface of the head was finally brought into firm contact by abduction of the thigh. An open tenotomy of some tendons and muscles was found necessary before the leg could be brought into proper position. The plain surfaces of the head and acetabulum were brought together by simply abducting the thigh, and the capsule and soft tissues were then sutured. The operation had the following advantages: (1) It assured bony union, brought two large bony surfaces together for ankylosis, and held them firmly by the mere correction of the deformity. (2) It produced a minimum amount of bony shortening. The patient made an uneventful recovery and walked at the end of nine weeks without cane or crutch. He went back to his work as patrolman in four months and had never lost a day on account of his hip since. Dr. Albee had done this operation five times, all patients having advanced arthritis deformans of the hip. The shock of operation was very slight in every case, and all had made excellent recoveries and all had splendid functional results.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

Minnesota State Medical Examing Board.

January, 1908.

ANATOMY AND HISTOLOGY.

1. Give the histology of a nerve trunk.
2. Describe the origin, relations and distribution of the fifth pair of cranial nerves.
3. Describe the cardiac valves. Between what points on the surface are they situated?
4. Describe the fourth ventricle.
5. Describe the portal vein.
6. Describe the thoracic duct.
7. Describe the azygos veins.

8. Give names and general description of the flexor muscles of the forearm.
9. Describe the pronator muscles.
10. Describe the supinator muscles.

PHYSIOLOGY.

1. Describe the human blood, giving reaction, specific gravity, constituents, etc.
2. Describe the secretion of urine.
3. What is the composition, reaction, and function of the pancreatic juice?
4. Describe the pulmonary circulation and the changes which are produced in the blood by aeration.
5. Describe the secretion of milk, and give the composition of human milk and cow's milk.
6. What are the functions of the skin?
7. Describe the normal heart sounds, give probable reasons for same, and tell where best heard?
8. Enumerate the functions of the spinal cord and its special centers.
9. Explain the physiology of visual accommodation to light and distance.
10. Give the physiology of menstruation.

Note—Credits will be given for all diagrams used in explaining questions.

MATERIA MEDICA AND TOXICOLOGY.

1. Write a model prescription for acute bronchitis, giving reasons for use of each ingredient and explaining each step in the writing of the prescription.
2. (a) What are the symptoms of chronic morphine poisoning? (b) What are the symptoms caused by abrupt withdrawal of the drug? (c) What is the treatment of acute poisoning?
3. (a) From what is acetanilid derived? (b) Explain its effects. (c) Give treatment of acute poisoning.
4. (a) From what is hyoscine derived? (b) What is the dose of hydrobromide? Its physiological effects? Some of its therapeutic uses?
5. Give rule for dosage for children according to age.
6. Give in parallel columns, the diagnosis between acute ptomaine poisoning and acute poisoning by arsenic?
7. Explain the action of chloroform as an anesthetic and tell how you would administer it and with what precautions.
8. What are the adult doses of and physiological antidotes for Tr. strophanthus, apomorphine (by hypodermic), carbolic acid, and chloral hydrate?
9. Explain the action on the bowels of opium, thymol, and bismuth subnitrate.
10. (a) What is the U. S. Pharmacopœia? (b) What is the National Formulary? (c) What is a fluid extract? (d) What is a chemical antidote?

CHEMISTRY AND URANALYSIS.

1. Define specific gravity; an acid; a base; allotropy; synthesis.
2. (a) Give law of definite proportions. (b) Give tests for iodine, silver, mercury.
3. Give a test for sewage contamination of drinking water. What do you consider a good drinking water?
4. Give fully the clinical significance of alubuminuria. Name the urinary casts and the commonly associated kidney lesions.
5. Give a test for indican. What is its clinical significance?
6. What is the diazo-reaction of Ehrlich and its significance?
7. How do you estimate urea?
8. What is the diagnostic value of tests for organic acids found in stomach contents? Describe a test for lactic acid.
9. What is the normal reaction of cow's milk? Why is it important to determine the reaction before sterilization?
10. Give test for blood. What is the freezing point for blood?

BACTERIOLOGY.

1. In what diseases have the specific microorganisms been recovered from the blood?
2. (a) Give fully the technique of finding the tubercle bacillus in suspected sputum. (b) What is Gram's and Weigert's method of staining? Illustrate its differential value.
3. Describe the preparation of diphtheria antitoxin. How is its action explained?
4. Describe the morphology of the microorganisms causing tetanus, gonorrhea, spinal meningitis, relapsing fever. Give mode of infection.
5. (a) What is the present status of the bacteriology of scarlet fever, rheumatism, and syphilis? (b) Give morphology and cultural properties of the *Diplococcus pneumoniæ*.

PRACTICE OF MEDICINE.

1. Describe lichen planus.
2. Describe a typical case of acute miliary tuberculosis.
3. Define bronchiectasis? Give symptoms and physical signs.
4. Nephrolithiasis. Give symptoms fully. Differentiate from appendicitis.
5. Describe the usual symptoms in the secondary stage of syphilis.
6. Differentiate in parallel columns, gastric ulcer and gastralgia.
7. Hereditary ataxia (Friedreich's disease): Describe symptoms and usual course of disease.
8. Differentiate articular rheumatism and arthritis deformans.
9. Define arteriosclerosis. Give usual causes. With what other diseases is it frequently associated?
10. Hematuria: Give principal causes. How would you determine source of hemorrhage?

SURGERY.

1. (a) Give the surgical definition of "tumor." (b) Classify tumors histologically.
2. (a) Define "wound." (b) Give classification.
3. Give in detail treatment of a punctured wound involving the deep palmar arch.
4. State fully how you would treat a blank cartridge wound of the palm of the hand, and give reason for your plan of treatment.
5. Describe step by step the operation of ligature of the ulnar artery at the wrist, giving linear and muscular guides.
6. (a) Define "fracture." (b) Give general classification of fractures.
7. Pathology, symptoms, and treatment of Pott's fracture.
8. Tracheotomy: Describe operation and after treatment.
9. How would you reach a diagnosis in a case of suspected coxitis?
10. Describe fully the treatment of strangulated inguinal hernia.

GYNECOLOGY.

1. Give differential diagnosis between ovarian cyst and extrauterine pregnancy.
2. Describe your method of repairing a lacerated cervix.
3. Describe inversion of the uterus, giving symptoms, diagnosis, and treatment.
4. Describe uterine polypus, give symptoms, diagnosis, and treatment.
5. (a) Give two indications for hysterectomy. (b) Your reasons for chosing vaginal or abdominal route.

DISEASES OF CHILDREN.

1. Give etiology, pathology, and diagnosis of rachitis.
2. Give symptoms of pertussis and differentiate it from acute bronchitis.
3. What alterations would you make in modified milk to overcome constipation.
4. Give briefly differential diagnosis between epilepsy, convulsions due to intestinal irritation, and uremic convulsions.
5. Give symptoms and treatment of dilatation of the stomach.

OBSTETRICS.

1. Describe fully your management of a case of face presentation.
2. Describe your management of a case of neglected transverse presentation where version fails.
3. In contracted and deformed pelvis, enumerate the different methods to be considered in delivery of child and state your reasons for each.
4. Describe fully your management of prolapse of cord.
5. Give your treatment of different grades of asphyxia in the new born.
6. Describe symptoms and treatment of ectopic pregnancy.
7. Describe caput succadaneum and cephalhematoma and give causes of each.
8. Give indications for podalic version.
9. Give your treatment of puerperal septicemia.
10. Give etiology and treatment of mastitis.

PATHOLOGY.

1. Give pathology of anemia, pernicious anemia, and chlorosis.
2. Describe changes in chronic alcoholism.

3. Pathology of carcinoma of liver.
4. Give pathological findings in typhoid fever.
5. Describe pathological changes in nephritis.

EYE AND EAR.

1. Differentiate glaucoma and iritis.
2. Describe choked disc and in what diseases we may expect to find it.
3. Define myopia, hypermetropia, astigmatism.
4. How would you treat a discharging ear?
5. Describe otitis media.

MEDICAL JURISPRUDENCE.

1. Describe phenomena and signs of death.
2. How would you distinguish human bood from that of other sources?
3. Describe death by hanging; how would you determine whether penal or suicidal, ante- or post-mortem?
4. What is life insurance and upon what does the premium rate depend?
5. What is the normal duration of pregnancy and what are the most important signs of delivery in the living and in the dead?

PREVENTIVE MEDICINE.

1. What quarantine measures are necessary in a case of (a) smallpox, (b) diphtheria, (c) scarlet fever?
2. Describe in detail how you would manage cases of typhoid for the protection of the community.
3. How are the following diseases transmitted: (a) Diphtheria, (b) yellow fever, (c) typhoid fever?
4. How long would you keep in quarantine a case of (a) scarlet fever, (b) diphtheria, (c) smallpox?
5. Give a simple, practical method of ventilating a dwelling in this climate during the winter season.

ANSWERS TO STATE BOARD EXAMINATION QUESTIONS.

Minnesota State Medical Examining Board.

January, 1908.

ANATOMY AND HISTOLOGY.

3. *Relation of the cardiac valves to the chest wall*: "The aortic valves lie behind the third intercostal space, close to the left side of the sternum. The pulmonary valves lie in front of the aortic behind the junction of the third rib, on the left side, with the sternum. The tricuspid valves lie behind the middle of the sternum, about the level of the fourth costal cartilage. The mitral valves lie behind the third intercostal space, about one inch to the left of the sternum." (Holden.)

PHYSIOLOGY.

1. *The physical properties of blood*: Fluid, somewhat viscid, red, specific gravity from 1055 to 1062, alkaline reaction, saltish taste, characteristic odor, variable temperature (average about 100 degrees F.).

The *constituents of the blood* are plasma and corpuscles. The *plasma* consists of water and solids (proteids, extractives, and inorganic salts). The *red corpuscles* consist of water and solids (hemoglobin, proteids, fat, and inorganic salts). The *white corpuscles* consist of water and solids (proteid, leuconuclein, lecithin, histon, etc.).

The *red blood corpuscles* are biconcave discs, about 1-3200 of an inch in diameter; they are nonnucleated, and there are about 4,500,000 or 5,000,000 of them in each cubic millimeter of blood. They are elastic and soft, and their shape is changed by pressure, but is promptly regained on the removal of the pressure. Their color is yellowish. They contain hemoglobin.

Their *function* is to carry oxygen from the lungs to the tissues.

The *white blood cells* are spheroidal masses, varying in size, having no cell wall, and containing one or more nuclei; there are about 7,000 to 10,000 of them in each cubic millimeter of blood. They differ much in appearance, and are divided into (1) small mononuclear leucocytes, or lymphocytes, (2) large mononuclear (3) transitional, (4) polynuclear, or polymorphonuclear, or neutrophile, and (5) eosinophile. They are all more or less granular, particularly the last two varieties named. They are probably formed in the spleen, lymphatic glands, and lymphoid tissues. Their fate is uncertain; it has been asserted that they are converted into red blood cells; they play a part in the formation of fibrin ferment; they are sometimes converted into pus cells. Their functions are (1) to serve as a protection to the body from the incursions of pathogenic microorganisms; (2) they take some part in the process of the coagulation of the blood; (3) they aid in the absorption of fats and peptones from the intestine, and (4) they help to maintain the proper proteid content of the blood plasma.

There are also *platelets*, which are very small, colorless, irregular shaped bodies; they are about one-fourth the diameter of a red corpuscle. Their function is not determined; it is possible that they take some part in the coagulation of the blood. In number they vary from about 200,000 to more than 500,000 in each cubic millimeter of blood.

Plasm conveys nutriment to the tissues; it holds in solution the carbon dioxide and water which it receives from the tissues, and takes them to be eliminated by the lungs, kidneys, and skin; it also holds in solution urea and other nitrogenous substances that are taken to and excreted by the liver or kidneys.

3. Pancreatic Juice: *Composition*: Water and solids, the latter consisting of three enzymes (trypsin, amylopsin, and steapsin), proteid material, soap, fats, lecithin, and inorganic salts (carbonate of sodium, chloride of sodium, and phosphates of sodium, calcium, and magnesium).

The *reaction* is alkaline, due to sodium carbonate.

The *functions*: (1) It changes proteids into proteoses and peptones, and afterwards decomposes them into leucin and tyrosin; (2) it converts starch into maltose; (3) it emulsifies and saponifies fats, and (4) it causes milk to curdle.

6. *The functions of the skin* are: Protection, sense of touch, excretion, regulation of body temperature, absorption, and respiration.

7. The *causes* producing the *first* sound of the heart are not definitely ascertained; the following are supposed to be causatory factors: (1) the vibration and closure of the auriculo-ventricular valves, (2) the muscular sound produced by the contraction of the ventricles, and (3) the cardiac impulse against the chest wall.

The *second* sound is caused by the vibration due to the closure of the semilunar valves.

The first sound is heard best at the apex; the second sound is heard best at the base.

8. The *functions of the spinal cord* are: (1) The conduction of impulses and impressions; (2) as a series of nerve centers.

The *special centers in the spinal cord* are the centers for (1) cilio spinal center, (2) for sphincter of bladder, (3) for sphincter of rectum, (4) for erection, (5) for contraction of uterus, (6) for maintaining tonus of muscles.

9. "*Mechanism of Accommodation.*—The lens is an elastic structure, and when released from the flattening influence of its suspensory ligament tends to assume a spherical shape. During accommodation the ciliary muscle (especially the circular fibers) contracts, drawing forward the choroid and relaxing the suspensory ligament; this diminishes the tension of the lens capsule and allows the inherent elasticity of the lens to increase its convexity. The change in curvature affects chiefly the anterior surface of the lens. This is Helmholtz's theory and the one usually accepted. Lately Tscherning has advanced a different theory; he maintains that the ciliary muscle increases the tension of the suspensory ligament during contraction and that this causes peripheral flattening of the lens with bulging anteriorly at its center. The act of accommodation is accompanied by contraction of the pupil, and (in binocular vision) by convergence of the visual lines." (May's *Diseases of the Eye.*)

MATERIA MEDICA AND TOXICOLOGY.

2. (*a*) *Symptoms of chronic morphine poisoning*: Great mental depression, irresolution, loss of self-control, great longing for the drug, nausea, insomnia, anxiety, melancholia, feeble pulse, diarrhea, muscular cramps, and "lying."

(*b*) *Symptoms caused by abrupt withdrawal of the drug*: Diarrhea, vomiting, insomnia.

(*c*) *Treatment of acute morphine poisoning*: "Wash out the stomach with a dilute solution of potassium permanganate, leaving about 500 c.c. in the stomach; and maintain the respiration. In the first or second stage the 'ambulatory treatment' should be adopted to prevent, if possible, the establishment of the third stage. If this stage develop, the main reliance is to be placed in maintaining the respiration by artificial methods, until the poison has been eliminated. Strong coffee, or caffein, by the mouth or rectum, are of benefit. The same cannot be said of atropin. The urine should be drawn by the catheter." (Witthaus' *Essentials of Chemistry.*)

3. (*a*) Acetanilid is derived from aniline, by the action on it of glacial acetic acid.

(*b*) The continuous use of acetanilid may give rise to decrease in the number of red blood cells; the face is livid and covered with perspiration, the respirations become slow and shallow, the pulse soft, compressible, and gradually weaker.

(*c*) Treatment: Stop further administration of the drug, then support the patient by stimulants, warmth and strychnine.

4. (*a*) Hyoscine is derived from Hyoscyamus.

(*b*) The dose of the hydrobromide is gr. 1/128.

Its *physiological effects*: it quiets the cerebrum and produces sleep; it may also produce delirium; it also causes loss of reflex action.

It is *used* as a hypnotic, in acute mania, insomnia, hysteria; also in morphine and alcohol habit; it is also used as a sedative mydriatic in plastic iritis.

5. Let x = the age of a patient; then $\frac{x}{x+12}$ = the fraction of the adult dose which the patient should receive. Thus, a patient of four years old should receive $\frac{4}{4+12} = \frac{4}{16} = \frac{1}{4}$ of an adult dose.

6. The following table, from Gould and Pyle's *Cyclopedia of Medicine and Surgery*, gives the diagnosis between Ptomaine Poisoning, and Poisoning by Arsenic:

Ptomaine Poisoning.	*Arsenic Poisoning.*
1. Onset often from 2 to 24 hours.	1. Onset within half an hour.
2. Results from eating animal (nitrogenous) food.	2. History negative.
3. Nervous symptoms marked (twitching of facial muscles, tingling sensations, dilated pupils, convulsions).	3. Nervous phenomena, as seen in autointoxication, absent.
4. Early dyspnea, cyanosis.	4. Dyspnea comes on late in mineral poisoning.
5. Temperature often subnormal.	5. Temperature often elevated a degree or two.
6. Dryness of mouth and fauces, often bitter taste.	6. Metallic taste in mouth.
7. Vomitus contains mucus, contents of stomach, or bile.	7. Vomitus variable, often tinged with blood, and containing trace of poison.
8. Generally watery diarrhea, sometimes constipation.	8. Feces may contain blood and trace of poison.
9. Various cutaneous eruptions (scarlatinal eruptions, urticaria).	9. Cutaneous eruptions absent.

8.

	Adult Dose.	Physiological Antidote.
Tr. strophanthus	♏. viij	Nitroglycerin; amyl nitrite
Apomorphine (by hypodermic)	gr. 1/10	None
Carbolic acid	gr. j	Magnesium or sodium sulphate
Chloral hydrate	gr. xv	Strychnine.

9. *Opium* depresses the motor activity of the intestines, prevents peristalsis, and causes constipation.

Thymol is an intestinal antiseptic and disinfectant.

Bismuth subnitrate has but little effect on the bowels; it is mildly protective, and astringent.

10. (*a*) *The U. S. Pharmacopœia* is an official list of medicinal substances, with definitions, descriptions, or formulæ for their preparation; it is recognized by the medical profession of the United States, but has no legal authority.

(*b*) *The National Formulary* is a collection of preparations not contained in the U. S. Pharmacopœia.

(*c*) *Fluid extracts* are liquid alcoholic preparations of nearly uniform strength; each cubic centimeter of the fluid extract represents one gram of the drug.

(*d*) *A chemical antidote* is one that changes the chemical character of the poison, and so renders it inert.

CHEMISTRY AND URANALYSIS.

1. *Specific gravity* is the weight of a substance as compared with the weight of a like volume of a given substance, taken as a standard, under similar conditions of temperature and pressure.

An acid is a compound of an electronegative element or radical with hydrogen, part or all of which hydrogen it can part with in exchange for an electropositive element, without the formation of a base.

A *base* is a ternary compound capable of entering into double decomposition with an acid to produce a salt and water.

Allotropy is the property possessed by some elements (such as oxygen, sulphur, phosphorus) of appearing under different forms in which their general chemical characters are unchanged, but their physical properties vary.

Synthesis is the formation of compounds from elements or from simpler compounds.

2. (*a*) *The law of definite proportions*: The same compound always contains the same elements and in the same proportions.

(*b*) *Test for iodine*: Add starch paste; in the presence of iodine it becomes blue.

Test for silver: Add hydrochloric acid; in the presence of silver a white precipitate is formed which is insoluble in nitric acid, but soluble in ammonium hydroxide.

Test for mercury: The Reinsch test is as follows: To the suspected fluid add a little pure HCl; suspend in the fluid a small strip of bright copper foil, and boil. If a deposit forms on the copper, remove the copper, wash it with pure water, dry on filter paper, but be careful not to rub off the deposit. Coil up the copper, and put it into a clean dry, glass tube, open at both ends, and apply heat at the part where the copper is. If mercury is present there will appear in the cold part of the tube a mirror, which will be found on microscopical examination to consist of metallic globules of mercury.

4. (*a*) *Albumin* is found in the urine: "(1) In fevers, as typhoid and pneumonia. (2) In valvular heart lesions, degeneration of the heart muscles, diseases of the coronary arteries, impeded pulmonary circulation, in pregnancy by pressure upon the renal veins, in intestinal catarrh, and in Asiatic cholera. (3) In purpura, scurvy, leukemia, pernicious anemia, jaundice, diabetes, and syphilis. (4) After taking lead, mercury, iodine, phosphorus, arsenic, antimony, chloroform, cantharides, oxalic, carbolic, salicylic or the mineral acids, turpentine and nitrates. (5) In large amounts in acute nephritis and chronic parenchymatous nephritis; in small amounts in chronic interstitial nephritis and amyloid kidney." (Witthaus' *Essentials of Chemistry.*)

(*b*) "*Casts* in the urine occur in nephritis, and different varieties are found in the different forms of that disease. *Hyaline* casts occur in all forms of nephritis, in congestion of the kidneys, in jaundice, and even in health. *Waxy* casts occur especially in chronic parenchymatous nephritis. *Epithelial* casts occur especially in acute parenchymatous nephritis. *Granular* casts are especially common in chronic nephritis, but they may occur in acute nephritis. *Fatty* casts occur chiefly in chronic parenchymatous nephritis. *Blood* casts occur in acute and chronic hemorrhagic nephritis. *Pus* and *bacterial* casts are occasionally met with in suppurative nephritis." (From Stevens' *Practice of Medicine.*)

5. *Test for indican in the urine*: The urine is mixed with one-fifth its volume of 20 per cent. solution of lead acetate and filtered. The filtrate is mixed with an equal volume of fuming hydrochloric acid containing 3:1000 of ferric chlorid, a few drops of chloroform are added, and the mixture strongly shaken one to two minutes. With normal urine the chloroform remains colorless, or almost so; but if an excess of indoxyl compounds be present the chloroform is colored blue, and the depth of the color is a rough indication of the degree of the excess.

Indicanuria is found in hypochlorhydria; in hyperchlorhydria of gastric ulcer; in conditions in which there is diminished peristalsis of the small intestines, as in ileus and peritonitis, not in simple constipation; also in conditions in which putrefactive changes occur in the body elsewhere than in the intestine, as in empyema, putrid bronchitis, gangrene of the lungs, etc. (From Witthaus' *Essentials of Chemistry.*)

6. For the diazo reaction of Ehrlich, two solutions are required: (1) A saturated solution of sulphanilic acid in a mixture of 50 c.c. of hydrochloric acid and 950 c.c. of water; and (2) a 0.5 per cent. solution of sodium nitrite.

To make the test, 1 c.c. of (2) is added to 40 c.c. of (1) and the mixture thoroughly shaken. Equal quantities of this mixture and the urine to be tested are shaken together in a test tube, and 1 c.c. of ammonia is then floated upon the surface, when, in an affirmative result, a red band is formed at the junction of the fluids.

Its diagnostic value is uncertain. Von Jaksch "disclaims for this test any clinical importance whatever." Others have claimed that the reaction is pathognomonic of typhoid; but it has been found in other diseases besides typhoid—namely, phthisis, pneumonia, measles, scarlet fever, smallpox, and malaria.

7. A comparatively easy test for *Urea* is that of Fowler, based upon the loss of the specific gravity of the urine after the decomposition of the urea by hypochlorite. "To apply this method the specific gravity of the urine is carefully determined, as well as that of the liquor sodæ chlorinatæ (Squibb's). One volume of the urine is then mixed with exactly seven volumes of the liquor sodæ

chlorinatæ, and, after the first violence of the reaction has subsided, the mixture is shaken from time to time during an hour, when the decomposition is complete; the specific gravity of the mixture is then determined. As the reaction begins instantaneously when the urine and reagent are mixed, the specific gravity of the mixture must be calculated by adding together once the specific gravity of the urine and seven times the specific gravity of the liquor sodæ chlorinatæ, and dividing the sum by eight. From the quotient so obtained the specific gravity of the mixture after decomposition is subtracted; every degree of loss in specific gravity indicates 0.7791 gram of urea in 100 c.c. of urine. The specific gravity determinations must all be made at the same temperature; and that of the mixture only when the evolution of gas has ceased entirely." (Witthaus' *Manual of Chemistry.*)

8. The presence in the stomach contents, after a test meal, of considerable quantities of organic acids is supposed to be pathological. Lactic acid, particularly, is supposed to be diagnostic of cancer of the stomach. Organic acids, as a rule, denote pyloric stenosis, gastric dilatation, or deficient motor power of the stomach.

"*The presence of lactic acid* is detected by *Uffelmann's reagent,* which consists of a solution of Fe_2Cl_6 and phenol, diluted to an amethyst-blue color, which is changed to yellow by lactic acid. In order to avoid error by the action of other substances which have a like action upon the reagent, 10 c.c. of the filtered gastric contents are agitated with ether, and the ethereal extract separated and agitated with the reagent; or it may be evaporated, the residue dissolved in water, and the solution added to the reagent." (Witthaus' *Manual of Chemistry.*)

10. *Test for blood*: Let some of the stained material soak thoroughly in a very small quantity of saturated solution of sodium chloride. Put a few drops of the fluid on a slide, cover with a cover-glass, let evaporation occur, allow a drop of glacial acetic acid to enter from the side, and gently warm. On cooling, hæmin crystals form, and can be seen under the microscope.

The freezing point for blood is given as 0.56°.

BACTERIOLOGY.

1. The specific microorganisms have been recovered from the blood, in the following diseases: Typhoid, relapsing fever, cerebrospinal meningitis, malaria, diphtheria, erysipelas, influenza, tuberculosis, cholera, anthrax, pneumonia, syphilis (?), leprosy, bubonic plague, gonorrhea, tetanus.

2. (*a*) To demonstrate the existence of *tubercle bacilli* in the sputum: The sputum must be recent, free from particles of food or other foreign matter; select a cheesy-looking nodule and smear it on a slide, making the smear as thin as possible. Then cover it with some carbol-fuchsin, and let it steam over a small flame for about two minutes, care being taken that it does not boil. Wash it thoroughly in water and then decolorize by immersing it in a solution of any dilute mineral acid for about a minute. Then make a contrast stain with solution of Loeffler's methylene blue for about a minute; wash it again and examine with oil immersion lens. The tubercle bacilli will appear as thin red rods, while all other bacteria will appear blue.

PRACTICE OF MEDICINE.

9. *Arteriosclerosis* is a condition in which the walls of an artery, especially the intima, become hard, dry, and thickened.

Usual causes: Syphilis, alcoholism, gout, Bright's disease, overeating, and excessive muscular exertion. It is most liable to occur in old age.

It is *frequently associated* with: Chronic interstitial nephritis, chronic myocarditis, paralysis, and gangrene.

10. The *principal causes of hematuria* are: (1) Conditions in which the blood is affected, as in the infectious diseases, in scurvy, pernicious anemia, and purpura; (2) traumatism or inflammations in any part of the urinary tract; (3) congestion of the kidneys secondary to disease of the lungs, heart, or liver.

In *renal* hematuria the blood and urine are intimately mixed, tube casts are apt to be present, and there may be renal colic or pain in the lumbar region. In *vesical* hematuria the blood and urine are not so well mixed, and pure blood is apt to be passed at the end of urination. In *urethral hematuria* the urine first passed is bloody.

SURGERY.

4. After a blank-cartridge wound of the palm of the hand, the patient should be anesthetised, hemorrhage checked, dead tissue and any foreign matter should be removed, the wound thoroughly disinfected and drained, and it might be well to administer at once a prophylactic dose of antitetanic serum.

GYNECOLOGY.

1. In *extrauterine pregnancy,* see below—OBSTETRICS, Question 6.

In the *ovarian cyst*: The history must be taken very carefully, and there will be found absence of the chief signs of pregnancy; there may be the characteristic facies; and the tumor is soft and fluctuating.

5. (*a*) Two *indications for hysterectomy*: Carcinoma and fibroids.

(*b*) As to preference between the vaginal and abdominal routes, the following is taken from Garrigues' *Gynecology*: "If the vaginal route is available, it should be preferred, because it entails much less shock, requires a simple after-treatment, does not leave any visible cicatrix, predisposes less to hernia, and allows the patient to resume work in shorter time. On the other hand, the vaginal route is more difficult on account of the limited space. Hemorrhage is more troublesome to check, adhesions are harder to separate, and the bladder and intestine more exposed to injury and less accessible for repair. The pelvic cavity cannot be seen so well, and the abdominal not at all. If tissue is left to mortify, it emits an offensive odor."

OBSTETRICS.

2. In contracted and deformed pelvis, the different methods to be considered in delivery of the child are: (1) Induction of premature labor; (2) Forceps; (3) Version; (4) Craniotomy; (5) Cesarean section, or one of its modifications; (6) Symphyseotomy.

So many things have to be taken into consideration that it is quite impossible to lay down any hard and fast rules to govern every case. The following table (from King) is a safe guide:

When Conjugate Diameter of Brim measures:	The Mode of Delivery at Term is:
Between 4 and 3½ inches...	By Forceps.
Between 3½ and 2¾ inches.	By Forceps, Version. Symphyseotomy. Cesarean section, or Craniotomy, *pro re nata.*
Between 2¾ and 2 inches...	Cesarean section, if child alive. Craniotomy, if child dead.
At 2 inches or less.....	Cesarean section always. Craniotomy excluded, whether child dead or alive.

6. *Diagnosis*: "When extrauterine pregnancy exists there are: (1) The general or reflex symptoms of pregnancy; they have often come on after an uncertain period of sterility; nausea and vomiting appear aggravated. (2) Then comes a disordered menstruation, especially metrorrhagia, accompanied with gushes of blood, and with pelvic pain coincident with the above symptoms of pregnancy; pains are often very severe, with marked tenderness within the pelvis; such symptoms are highly suggestive. (3) There is the presence of a pelvic tumor characterized as a tense cyst, sensitive to the touch, actively pulsating; this tumor has a steady and progressive growth. In the first two months it has the size of a pigeon's egg; in the third month it has the size of a hen's egg; in the fourth month it has the size of two fists. (4) The os uteri is patulous; the uterus is displaced, but is slightly enlarged and empty. (5) Symptoms No. 2 may be absent until the end of the third month, when suddenly they become severe, with spasmodic pains, followed by the general symptoms of collapse. (6) Expulsion of the decidua, in part or whole. Nos. 1 and 2 are *presumptive signs;* Nos. 3 and 4 are *probable signs;* Nos. 5 and 6 are *positive signs.*" (*American Text-Book of Obstetrics.*)

Treatment consists in removal of the product of conception, by a laparotomy, as soon as the diagnosis is made.

8. The *indications for Podalic Version* are: (1) In transverse presentations: (2) in placenta prævia; (3) in malpresentations of the head; (4) in simple flattened pelvis, and in minor degrees of pelvic contraction; (5) in prolapsed funis; (6) in sudden death of the mother; and (7) in any case where speedy delivery is imperative.

PATHOLOGY.

1. In *secondary anemia,* the blood would show: (1) A diminution in the number of red corpuscles; (2) a diminution in the amount of hemoglobin, perhaps greater than that of the red corpuscles; (3) poikilocytosis, and variations in the size of the red corpuscles; (4) the presence of a few nucleated red corpuscles; (5) a moderate leucocytosis.

In *pernicious anemia* the blood would show: (1) A

diminution in the number of red corpuscles; (2) a relative increase in the amount of hemoglobin; (3) poikilocytosis; (4) the presence of nucleated red cells; (5) variation in the size of the red cells; (6) the leucocytes *may be* diminished.

The skin is usually discolored (yellowish); fatty degeneration of the heart is common; the liver may be fatty.

In *chlorosis,* the blood shows: (1) A great diminution in the amount of hemoglobin; (2) a slight diminution in the number of red corpuscles; (3) poikilocytosis; (4) occasionally a few nucleated red corpuscles; (5) a very slight leucocytosis.

The skin is generally yellowish-green, and the blood and conjunctiva pale.

EYE AND EAR.

	GLAUCOMA.	IRITIS.
Age	Over forty.	Any.
Tension	Plus.	Normal.
Congestion	General, especially scleral.	General, especially circumcorneal.
Cornea	Cloudy and steamy surface.	Cloudy.
Anterior chamber	Shallow.	Unchanged.
Pupil	Dilated, oval.	Contracted, synechiæ.
Pain	Severe, continuous.	Especially at night.
Vision	Much reduced.	Somewhat reduced.
Treatment	Eserine, pilocarpine iridectomy.	Atropine.

(From Alling and Griffin's *Diseases of the Eye and Ear.*)

2. *Choked disc* is a condition in which the optic papilla is swollen, congested, and inflamed; it is due to increased intracranial pressure.

It occurs in brain tumors, tuberculous meningitis, abscess of the brain, syphilis, nephritis, rheumatism, toxic agents (as lead or alcohol), infectious diseases, and anemia.

3. *Myopia* is a condition in which the anteroposterior axis of the eye is abnormally long, and parallel rays are focused in front of the retina.

Hypermetropia is a condition in which the anteroposterior axis of the eye is abnormally short, and parallel rays are focused behind the retina.

Astigmatism is a condition in which owing to a greater curvature of the eye in one meridian than in others, the refractive power of the eye varies.

4. *Treatment of a discharging ear*: Cleanliness and drainage are primary essentials. The discharge may be removed by sterile cotton, and the use of a warm mild antiseptic lotion. A solution of carbolic acid 1:40 may be dropped in and allowed to remain in the ear for a few minutes. Alcohol may be used when granulations appear. Treatment must only be undertaken once or twice a day, at the first; and the intervals gradually lengthened as the discharge becomes less. This must be persevered in for a long time. Paracentesis may be necessary, and later on, in complicated cases, the ossicles may have to be removed.

MEDICAL JURISPRUDENCE.

1. *Phenomena and signs of death,* are: The complete and permanent cessation of circulation and respiration, rigor mortis, loss of body heat, pallor of the body, putrefaction.

2. It is, probably, not possible to distinguish absolutely human blood from that of other mammals. By careful measurements of the red corpuscles under the high powers of modern microscopes, human blood can be readily distinguished from that of *some animals;* but in other cases, such as the differential diagnosis between the blood of a man and that of a dog, there is no absolute certainty.

3. A sure sign of *hanging antemortem* is the flow of saliva from the mouth, down the chin, and on to the chest. This could not occur in a case of *hanging postmortem,* as the secretion of saliva is a vital process.

4. *Life insurance* is a contract whereby the company insuring, in consideration of a certain premium payable as arranged, agrees to pay a certain amount at the death of the assured to his heirs or other designated person, or to the insured himself if living at a certain date.

The *premium rate depends* on: The age, physical condition, family history, occupation, residence, personal habits, health, etc., of the applicant.

PREVENTIVE MEDICINE.

2. Typhoid fever is preventible. When the municipal authorities do not consider it their duty to supply pure water, each household should boil all water that is to be used for drinking or for washing dishes, etc.; milk should be boiled also; and no ice should be put *in* water or other drink or food; flies should be kept out of the house as far as possible, by means of screens or otherwise; all discharges from the sick person must be disinfected; all utensils, dishes, etc., used by the patient must be thoroughly cleansed, and boiled every day; soiled linen must be soaked in a disinfectant solution before being washed; after each attendance on a patient, physicians, nurses, and others should wash their hands in a disinfectant; thorough sterilization of all bedding, etc., must be performed after the disease is over.

3. *Diphtheria* is transmitted by contact with those already infected, by fomites, by careless disposal of secretions, by coughing or sneezing whereby the bacilli are carried through the air to the nose or mouth of others.

Yellow fever is transmitted through the bite of an infected mosquito (*Stegomyia fasciata*).

Typhoid fever is transmitted through the food and drink becoming contaminated; flies may aid in this contamination.

4. PERIOD OF QUARANTINE for: (*a*) *Scarlet fever*: till the patient is quite free from sore throat or discharges of any kind, and the desquamation has entirely disappeared; generally six to eight weeks.

(*b*) *Diphtheria*: till the patient is free from all signs of congestion or rhinitis, and continued bacteriological examination is persistently negative.

(*c*) *Smallpox*: till all crusts or scabs have entirely disappeared.

BULLETIN OF APPROACHING EXAMINATIONS †

STATE.	NAME AND ADDRESS OF SECRETARY.	PLACE AND DATE OF NEXT EXAMINATION.	
Alabama*	W. H. Sanders, Montgomery	Montgomery	June 16
Arizona*	Ancil Martin, Phoenix	Phoenix	July 6
Arkansas*	F. T. Murphy, Brinkley	Little Rock	July 14
California*	Chas. L. Tisdale, 1879 Sutter Street, San Francisco	San Francisco	August 4
Colorado	S. D. Van Meter, 1723 Tremont Street, Denver	Denver	July 7
Connecticut*	Chas. A. Tuttle, New Haven	New Haven	July 14
Delaware	J. H. Wilson, Dover	Dover	June 16
Dist. of Col'bia	Geo. C. Ober, Washington	Washington	July 14
Florida*	J. D. Fernandez, Jacksonville	Jacksonville	Nov. 11
Georgia	E. R. Anthony, Griffin	Atlanta	Oct. 6
Idaho	W. F. Howard, Pocatello	Boise	October 6

* No Reciprocity recognized by these States.

† Applicants should in every case write to the secretary for latest details regarding the examination in any particular State.

Utah at present reciprocates with Colorado, Georgia, Illinois, Indiana, Iowa, Kansas, Maine, Michigan, Minnesota, Missouri, South Carolina, and Wisconsin.

Alabama.—The new law regulating the practice of of medicine in this State requires an examination of all who desire to practice their profession. Diplomas are not necessary; there is no reciprocity; and no temporary licenses are granted.

New Instruments.

A NEW ADENOID CURETTE.*

By SAMUEL GOLDSTEIN, A.B., M.D.,

NEW YORK.

ATTENDING SURGEON AND CHIEF OF CLINIC, THROAT DEPARTMENT OF THE NEW YORK THROAT, NOSE, AND LUNG HOSPITAL.

The use of the curette is undoubtedly becoming more and more popular, and deservedly so, for the rapid and safe removal of the adenoid growth. Our literature in general furnishes so much upon the subject, that the writer, in introducing this instrument, need hardly dwell upon what is so well understood. In so far as the necessity for general anesthesia is concerned, there are many and divers opinions expressed, some laryngologists extolling the general employment of an anesthetic—others are earnestly opposed to the same. Much can be stated for both sides, but I prefer to leave that as a matter of choice to the respective advocates of both methods. In the past, and with some operators at the present time, the general operative technique consisted in employing some form of adenoid forceps, and then completing the operation by cleaning up with curettes of various forms and sizes.

These procedures often necessitated the expenditure of considerable time; the liability of leaving behind some fragments of tissue, especially if the finger was not introduced in the finale of the operation—and thus at times incurring the danger of secondary hemorrhage, infrequent, perhaps, but sufficiently serious where the accident occurred.

With the instrument now presented, we have operated within the shortest time limit, with a single introduction of this curette, making one clean cut, and completely removing the adenoid growth. The curette is made in two sizes; is somewhat stirrup-shaped, with a straight sharp cutting blade, placed at right angles to the handle; the sides of the fenestra are rounded, so that, when properly used, all danger of injury to the Eustachian orifices is eliminated. The curette is introduced behind the palate in the usual manner, the upper part of the blade placed as high as possible in the nasopharynx, just touching the posterior end of the septum; the entire adenoid growth is engaged in the fenestra of the instrument, its cutting blade pressed smartly against the base of the growth, and with one free, sweeping movement backward and downward, the full growth is removed. The operator if he be in any doubt may satisfy himself that he has thus completed the operation by the introduction of the examining finger. This curette will also be found to be very serviceable in the clean and rapid removal, at one séance, of the enlarged follicles or granulations so frequently encountered in cases of chronic follicular pharyngitis. Here again speedy and deft operative work can be accomplished without any fear of endangering the integrity of the basic mucous membrane of the posterior wall of the pharynx. Mr. I. S. Goldstein of the surgical instrument department of E. B. Meyrowitz of this city, has most successfully perfected my designs.

1335 MADISON AVENUE.

MELÆNA NEONATORUM WITH REPORT OF A CASE CURED BY TRANSFUSION.

By SAMUEL W. LAMBERT M.D.,

NEW YORK.

Although the case which I have selected to report to the Practitioners' Society has received some notoriety in the daily press, it seems nevertheless worthy of a careful clinical study. The baby was born of healthy parents and was delivered after a ten-hour labor by an easy low forceps operation at 5 A.M. on March 4. The child was a girl, and appeared to be healthy, weighed eight pounds and twelve ounces, breathed and cried at once, and showed no signs of asphyxia. The blades of the forceps made slight marks over the right zygoma and behind the left ear; there was no abrasion of the skin. Five hours after birth the cord was retied because of slight oozing from the cut end. Twelve hours after birth a thickened, dark-colored spot was noticed on the right side of the tongue which was thought to be a nevus, but which has cleared up since and was undoubtedly a hematoma. Three hours later the baby's temperature was 102.2°, and it was put to the breast for the first time. After a quiet night the baby's morning temperature was 102°. She looked pale, and a slight amount of blood was noticed when the mouth was washed. She slept quietly all that morning, but became restless in the afternoon: her temperature at 4 P.M. was 103.4°. She grew markedly paler, cried continuously, and began to bleed slowly but steadily from the nose, and a hematoma appeared in the scalp behind the left ear. At 9 P.M. this subcutaneous bleeding had extended down the neck over the muscles, across the median line to the other ear across the coronal suture over the frontal bone, and forward under the left ear to the angle of the jaw. The bleeding from the nose was continuous and quite profuse. The temperature was 102.3°, a dark meconium stool gave a very positive reaction for blood, but the urine was of normal color. The baby was of waxen pallor. The diagnosis of melena was made, and treatment instituted upon the theory of its being an intestinal infection. One dose of thirty minims of castor oil and two grain doses of calcium lactate every two hours was given during the night. During March 6 the child did not seem to grow worse as rapidly. The scalp hematoma increased in size and tenseness, and the paleness of the skin increased, but the temperature gradually fell from the maximum of the attack at 2 A.M. (104.4°) till it reached 97.4° at 3 P.M., the nasal bleeding became less constant, and the baby nursed regularly. In the evening of March 6 and during March 7, there was some vomiting of watery fluid containing partially digested blood, especially after taking the calcium lactate, which was stopped. Adrenalin was tried in the nose at this time, but without effect. The feedings had to be by dropper, for the baby refused to nurse. The temperature range was 97.8° to 99.4°.

On the morning of March 8 the case seemed hopeless. During this day the baby's skin was waxen white and the mucous membranes without color; the nasal bleeding was continuous; the vomited matter contained food curds, dark blood, and at times bright clots; the stools were frequent and contained bright red blood; the subcutaneous hematoma on the scalp increased until the right eye was closed and ecchymotic spots appeared on the legs; the respiration was rapid and superficial; the pulse weak, counting 150 just before the operative procedure.

It was decided to attempt a direct transfusion of blood from the father of the infant by end-to-end anastomosis of the two blood-vessels after the manner devised by Dr. Carrel of the Rockefeller Institute. This was done through the skillful surgical manipulation of Dr. Carrel himself and Dr. Geo. E. Brewer. The right popliteal vein of the baby was sutured to the left radial artery of the child's father, without anesthetic to either patient, and enough blood was allowed to flow into the baby to change her skin from a pale transparent whiteness to a brilliant red color. No measure of the amount of blood was possible, but the evidences of a sufficient quantity were manifold. She began to cry lustily and to struggle against the bandages which held her strapped to an ironing-board. The wound in the leg up to this time had oozed a slight amount of pale watery blood, which did not clot well. It began to bleed freely and the blood promptly clotted. The nosebleed stopped instantly. The pulse became full and strong and slowed down, and the respirations were deep and full. As soon as the wound was sutured and dressed the baby was fed an ounce of milk, which she took ravenously and retained, and immediately went to sleep.

Since the ending of the transfusion there has been no hemorrhage, no vomiting, and no diarrhea. Convalescence from the operation was uninterrupted except for a slight infection of the wound. There was no evidence of hemolytic action at any time, and all the symptoms of melena ceased at once. The next morning the baby was found to be fourteen ounces below her birth weight. She has gained steadily since, and now, eight weeks after birth, she weights ten pounds fifteen ounces. The hematoma was absorbed rapidly, except for a slight discoloration of the upper lid of the right eye, which still persists. The stools became of normal character two days after the operation. The wound is healed, and the child appears to be a normal child of its age to-day. The striking thing in the case is that the disease ceased suddenly, and the child has been cured from the moment of the transfusion of blood.

This case presents a complete résumé of the symptomatology of melena, and the condition was easily differentiated from the other various kinds of hem-

orrhage to which the newborn are liable. The essential points were the early nosebleed, the rapidly increasing pallor and anemia, the febrile action, and the restlessness followed by the characteristic bloody vomit and stools and the subcutaneous ecchymoses.

The disease is one of the oldest known to man, although it is of comparatively infrequent occurrence. The latest statistics (Shukowsky, 1907) place its frequency at 1 in 1,000, or 29 in 30,000 living births.

Melena is a disease of the first two weeks of life, and usually begins in the first two days, the latest recorded case found began on the eighteenth day of life. (Genrich, quoted by Shukowsky.) It attacks the sexes equally, and well-developed children equally with the poorly-nourished.

Heredity seems to have no influence either as to the presence of true hemophilia or of hereditary syphilis. An interesting case which tends to disprove these influences is that of a pair of twins, one of whom died of melena, while the other was free of the disease. No influence has been proved from the effect of obstetrical operations or accidents, or from errors of anatomical development.

The results of pathological anatomy have failed to show any constant or fixed lesion. The various lesions in the cranium and those in the gastro-intestinal tract which have been described must be classified as chance lesions only. No rational explanation of the symptom syndrome of melena has ever been suggested as a result of fairly numerous autopsy examinations.

The prognosis has been extremely grave, and the mortality has varied in the experience of several observers from 50 to 80 per cent. Treatment also has been most unsatisfactory. A great variety of astringents—various preparations of ergot, subcutaneous injections of salines and of artificial serum, cold irrigations, hypodermic use of 2 per cent. gelatin solutions in saline, antisyphilitic medication, and rectal and gastric lavage have all been tried with great lack of successful results. To the above one must add the equally unsuccessful use of cathartics and calcium salts in the case which is the text for this paper. The best results in the past have been secured from the use of gelatin and gastric and colonic lavage (Shukowsky). The cure of this case by transfusion leads to certain theoretical conclusions as to the etiology of melena which are interesting and which subsequent investigation may prove of great interest.

The theories of the etiology of no other disease have undergone more varied and more radical changes than those of melena. This disease has always attracted attention, and its etiology has been subject to the fashions and temporary fads of the prevalent medical theories of the moment. Its essential nature remains unknown at the present day. Lequeux published a thesis on this disease in the Paris series of 1906, and called attention to this lack of accurate knowledge by suggesting four periods of historical interest in the study of melena.

The first period up to 1825 is called that of *confusion*, and the explanations of the cases reported include such causes as plethora, asphyxia, passive hyperemia, and congestion of the mesenteric arteries.

The second period from 1825 to 1835 is known as that of *clinical study*. The causative factor is suggested as an ulceration of the alimentary canal, too early tying of the umbilical cord, and, equally supported by other authors, a too late tying of the same.

The third period is that of *pathological anatomy*, and extends from 1838 to 1875. The numerous lesions found in the newborn have all been held responsible for this symptom complex: Brain injuries from birth hemorrhage, ulcers of the intestines, including the embolic theory of such ulcer formation, patency of the *ductus arteriosus*, congenital heart lesions.

The final period of *laboratory study*, from 1875 to date, has not cleared up the obscurities of the disease, although all the power of investigation of bacteriology has been brought to bear upon it. At least ten different bacterial causes have been found in individual cases both in pure culture and in various combinations. The list includes streptococci and staphylococci, pneumococci, *Bacillus pyocyaneus*, *B. lactis aërogenes*, *B. coli*, and even the specific germs of typhoid and diphtheria. An interesting claim was made by Gaertner in 1893 for the discovery of a specific bacillus, but subsequent study proved his claims to be untenable. The bacteriological findings have been too variable to prove any specific infection. The relation of syphilis as a cause has been invoked to explain the symptoms of melena on a modern theory of "weakness of the walls of the blood-vessels," and various authors have referred to special hemorrhages occurring in the course of the disease as a cause of the symptoms. Hamill's cases of hemorrhages into the suprarenal capsules, and the cases of cerebral hemorrhage of various authors, are examples of this faulty logic by which the symptoms are explained by interference with the adrenal glands in the one case, and by nervous influences in the other.

Lequeux concludes that melena is a symptom syndrome due to several causes, that certain predisposing conditions, of which syphilis is one, will cause certain infections to bring about the development of the disease. The same idea is expressed by Holt that melena is due to "changes in the blood or to changes in the blood-vessels, or to both, whereby the vessels are no longer able to hold their blood."

Abt, writing in 1903, reaches the same conclusion, as follows: "Future research in the etiology of this disease should be directed along the line of histological examination of the minute blood-vessels contemplating also conditions governing the clotting of the blood."

The modern theories of the chemistry of the blood, of its clotting, of its cellular structure, have been appealed to by Lequeux to explain these phenomena of hemorrhage, but a sufficient number of observations and experiments are lacking in his work to make these views of more than theoretical value. He formulates the sequence of events which probably occur prior to these hemorrhages, thus: "An increase in the bulk of the circulating blood; a change and weakness in the blood-vessels; a diminished power of coagulation in the blood, which becomes fluid, and has no tendency to limit its extravasation; difficulty with vasomotor function, resulting in a passive dilatation of the vessels, and a final rupture caused by changes in the vessel wall restricting its elasticity." In these recent opinions special stress is laid upon the condition of the blood-vessels.

The tendency to apply the newest theories of pathology and physiology to explain the unknown has been referred to as characteristic of the older discussions; it is found as well in the latest literature of melena. The older theories of embolism, of circulation, congestions, and of asphyxia, have

been discarded, and explanations by disturbance of cerebral centers by changes in internal secretion, especially of the suprarenal glands, or by some undiscovered lesion of hereditary syphilis, have been offered both with and without an added bacterial infection. The latest accepted theories of melæna neonatorum point not to ulceration or to gross lesions, but to the capillary blood-vessels as the seat of the bleeding, and the clinical picture of these cases is undoubtedly very like that of an infection as the etiological factor. But the course and the remarkable cure of the case reported here would seem to disprove both the infectious theory of its origin and the blood-vessel explanation of the diapedesis of red cells and disturbed osmosis resulting in the capillary hemorrhages.

To review the facts of the case: Hemorrhages and fever began simultaneously, normal temperature was reached forty hours after the onset of fever, but the hemorrhages became progressively worse, for three days after all fever had disappeared. At time of operation the baby was in a dying state, and had palpably only a few hours to live—immediately afterward the baby was in perfect health. There was no period of convalescence.

Such a sudden change in condition could not be due to a structural regeneration in the capillary vessels, nor to a sudden overcoming of an infection; clinical experience will permit of no such inference. Neither the crisis of a pneumonia nor the relief of a spasmodic croup can be compared with the observed fact in this case, either from the point of view of reversal of pathological condition, or of lapse of time necessary to bring it about.

The only possible explanation of so rapid a change must be found in a chemical condition of the blood. And the final conclusion as to the nature of the disease is that melæna neonatorum is a congenital malformation of the blood of unknown chemical nature. The solution of the problem of its etiology is to be found in a chemical study of the processes of osmosis in the capillary vessels, of the chemistry of blood coagulation, and along kindred lines which are for the most part new and untouched.

A complete bibliography of this disease will be found at the end of Dr. Lequeux's Thesis. The following articles have been especially consulted in the preparation of this article:

THE DIFFERENTIAL DIAGNOSIS OF MENINGOCOCCUS CEREBROSPINAL MENINGITIS FROM OTHER TYPES OF CEREBROSPINAL MENINGITIS.*

By HENRY W. BERG, M.D.,
NEW YORK.
ATTENDING PHYSICIAN TO THE WILLARD PARKER AND RIVERSIDE HOSPITALS, ADJUNCT PHYSICIAN TO MT. SINAI HOSPITAL, INSTRUCTOR IN CONTAGIOUS DISEASES, COLUMBIA UNIVERSITY.

All epidemics of meningococcus cerebrospinal meningitis are followed by several years during which, while the disease is no longer epidemic, sporadic cases are constantly occurring in sufficient number to warrant a maintained interest on the part of the general practitioner upon whom the burden of diagnosis and treatment naturally falls. At present the disease is sufficiently frequent to make a discussion of its differential diagnosis opportune. Recent developments in the serum treatment of the disease by the Flexner serum add a further element of interest, so that I feel that no apology is necessary for discussing the differential diagnosis of this disease. The symptom complex of well marked and developed cases of cerebrospinal meningitis is so distinctive that the diagnosis in such cases is readily made. On the other hand cases of incomplete symptomatology and irregular in type are difficult to classify and differentiate from other diseases. For in a general way the symptoms of this disease can be grouped under two classes, namely, those due to the affection of the cerebrospinal meninges and the brain, spinal cord, and nerve trunks, and, second, those due to the toxemia and sepsis. It follows, therefore, that we would expect, and do find, that cases of this disease must be differentiated on the one hand from other organic diseases of the cerebrospinal nervous system, and on the other hand from toxic and septic conditions and diseases, particularly such as are febrile in character. Taking up the latter class first, both meningococcus and other types of cerebrospinal meningitis must frequently be differentiated from cases of infectious diseases ushered in by or developing during their course, brain and spinal cord symptoms, due to toxemia of the nerve centers, and not to meningitis. Such diseases are typhoid and typhus fevers, lobar pneumonia, septic endocarditis, cryptogenetic and other types of general sepsis, dysentery and enterocolitis, especially in children; diphtheria, eclampsia infantum, toxemia of pregnancy, diabetic coma, uremia with febrile conditions, and rheumatism; even the acute eruptive diseases in the pre-eruptive stage, particularly those of the hemorrhagic type, may simulate, until the appearance of their characteristic eruptions, the clinical picture of this disease. This is frequently true in smallpox, scarlatina, and measles. In all of these diseases one of the forms of cerebrospinal meningitis may be diagnosticated when the patient is only suffering from a toxemia of the nerve centers which produces many of the characteristic symptoms of cerebrospinal meningitis.

There is a second class of cases in which the patient suffering from an infectious disease has as a complication a real organic cerebrospinal meningitis due either to the organism which causes the primary or basic infectious diseases from which the patient is suffering, or to a mixed infection with some other meningitis-producing organism.

Thus a real meningitis may complicate typhoid fever, pneumonia, tuberculosis, sepsis, scarlet fever, smallpox and measles, epidemic parotiditis and other infectious diseases, and the various types of metastatic cerebrospinal meningitis, which must be differentiated from the toxic pseudomeningitis just referred to, on account of the obvious differences in prognosis and therapy. In typhoid fever, pneumonia, tuberculosis, and sepsis the primary organism producing the general infection is itself capable of producing cerebrospinal meningitis, in the case of the pneumococcus and tubercle bacillus, indeed, a most fatal type of meningitis; in many of the other in-

*Read at a meeting of the Queens Borough Section of the Medical Association of the Greater City of New York.

fectious diseases the meningitis is due to a mixed infection with the eminently pus-producing organisms, influenza bacillus, colon bacillus, the meningococcus, and the pneumococcus, the meningococcus type of meningitis being especially frequent as a complicating infection during periods of epidemics of cerebrospinal meningitis. At such periods we shall frequently find, as I did in some of my cases in the epidemics of 1905-1906, cases of lobar pneumonia complicated by cerebrospinal meningitis, with the meningococcus present in the lumbar puncture fluid.

Third, it is important from a diagnostic, prognostic, and therapeutic standpoint to differentiate from each other cases of organic cerebrospinal meningitis of various bacterial pathogenesis. This is important not only in sporadic cases, but also in epidemic cases; for even during an epidemic not every case of meningitis is due to the meningococcus, for the cases of the pneumococcus, tuberculous, streptococcus, and staphylococcus meningitis will occur irrespective of the meningococcus cases occurring as a manifestation of a prevailing epidemic.

Finally, it is necessary to remember that the various organic diseases of the spinal cord and brain frequently are complicated by a partial or general cerebrospinal meningitis which may simulate epidemic cerebrospinal meningitis and must be recognized and carefully differentiated from it. Of this type is the traumatic meningitis following traumatism of the brain and spinal cord, skull or spinal column, also the meningitis complicating or due to tumors of and hemorrhages into the brain and spinal cord, and that due to various forms of myelitis and cerebritis. Particularly difficult is it to differentiate acute epidemic poliomyelitis anterior, or acute epidemic ascending paralysis or polioencephalitis inferior in some of the cases, from meningococcus cerebrospinal meningitis.

It is obvious then that the diagnostic recognition of meningococcus cerebrospinal meningitis resolves itself into (1) the differentiation of this disease from a pseudomeningeal symptom-complex of toxic origin; (2) its differentiation from other types of cerebrospinal meningitis, be they bacterial in origin or those complicating organic cerebrospinal lesions.

The essential symptoms necessary for a recognition of cerebrospinal meningitis in contradistinction to toxic pseudomeningitis are numerous, and a large proportion of them will be revealed by a careful examination in almost every case, acute or subacute, sporadic or epidemic. They are as extensive as would be expected in an acute infectious disease with a local lesion consisting of an inflammation of the brain and spinal cord and their meninges, and neuritis of cranial and spinal nerves.

The constitutional symptoms are chills, fever, slow pulse, temperature high or low, respiration slower than would be expected when the temperature is high. The temperature curve has nothing distinctive, but is characterized by variations of large amplitude and sudden in character. Symptoms due to the inflammation of the spinal cord and its meninges are stiffness of the neck and opisthotonos, pain in the spinal column, pain in the extremities, hyperesthesia of the surface, difficulty in urination, frequent urination, constipation or diarrhea, incontinence of urine and feces (paralysis of the sphincters in the last stages of the disease and during semicoma); Kernig's symptom (the most valuable and reliable physical sign that we have in cerebrospinal meningitis), eruptions on the skin of a herpetic character, affections of the joints (the joints most affected are the knees); the degree of joint trouble varies from simple pain on motion to redness, swelling, and pain, and all the manifestations present in acute articular rheumatism; diminution, but rarely absence, of patellar reflex, diminution of the skin reflex; the plantar reflex is rarely absent. Absence of the patellar reflex is due to increased intraspinal pressure in these cases and acts as an indication for a repetition of lumbar puncture. A recent symptom to which very little importance should be attached is the Babinski reflex. As you know, when the skin of the plantar surface of the foot is tickled, in some cases of meningitis, the toes are flexed and the *great toe* extended. This symptom is extremely unreliable. It occurs in some healthy children, and children suffering from other diseases. It does not occur in some well marked cases of cerebrospinal meningitis, and is of little practical utility as a diagnostic procedure.

The symptoms due to inflammation of the brain and medulla and their meninges, and neuritis of the cranial nerves are, headache, slow pulse, hydrocephalic cry, tâche cerebrale, vertigo, convulsions, delirium, coma, comavigil, Cheyne-Stokes respiration, photophobia, inequality, dilatation, or contraction of the pupils, ptosis, strabismus, optic neuritis, choked disk, atrophy of the optic nerves, iritis, iridochoroditis, keratitis, conjunctivitis, panophthalmitis, deafness due to neuritis of the auditory nerve, paralysis of the facial and other cranial nerves, hemiplegia, monoplegia, paraplegia, and diminished or absent conjunctival reflex.

The ears and eyes are frequently infected by the presence of the organism in the nasal cavity, giving rise in the ear to otitis media and interna, and mastoid disease.

Symptoms due to changes in the blood are increased leucocyte count (18,000 to 30,000 whites), a very valuable symptom which serves to differentiate these cases from typhoid fever and tuberculous meningitis. The increased leucocytosis is chiefly in the polymorphonuclear leucocytes. Eruptions of a petechial character, also skin eruptions resembling various types of erythema multiforme (these, while not of a trophic character, are probably due to blood changes). Finally, the most important symptom, absolutely distinctive, is elicited by the withdrawal of the cerebrospinal fluid by lumbar puncture and finding therein, microscopically, by spreads, Gram negative extra cellular and intracellular diplococci, and by culture, the diplococcus intracellularis meningitidis. The cytological examination of this fluid is also important; it generally shows polynuclear leucocytes about 90 per cent., and mononuclears about 10 per cent.

Of the symptoms due to the involvement of the spinal cord, the Kernig sign has been the most useful and distinctive, both in adults and children, in the cases I have seen. It is a decided enhancement of our objective diagnostic symptomatology. It is obtained by placing the patient upon the back, flexing the thigh at right angles with the abdomen, then extending the leg upon the thigh thus flexed. If Kernig's symptom be present the complete extension of the leg upon the thigh cannot be accomplished. The patient complains and cries out even when semicomatose, long before the leg is brought into a line with the

thigh, and the spasmodic muscular resistance cannot be overcome even by forcible effort. As the Kernig sign diminishes, the prognosis improves. This symptom is not limited to epidemic cerebrospinal meningitis, but is present in other forms of meningitis, primary or complicating, but, as I have said, I have never seen it absent in the cases of this disease which I have seen in this epidemic. It does not disappear sometimes for weeks after recovery is complete. Betancourt and Franca found it a very constant symptom in their large experience, it being present in over 90 per cent. of the cases. Sometimes, however, the symptom is only unilateral. It is generally unequal on the two sides. It is more marked with each exacerbation. In some fatal cases, with rapidly developing stupor, coma, slow pulse, dilated pupils, and convulsions, post-mortem examination generally shows an acute dilatation of the ventricles. This is a fatal condition, and ordinarily will give rise to the Macewen symptom, especially in young children. This symptom is founded upon the fact that the percussion note obtained by percussing the skull one or two inches behind the point of junction of the frontal, parietal, and temporal bones (a point known as the pterion) gives rise to a clearer note than is obtained over other parts of the vault of the skull, in cases in which there is increased tension (as from abscess) of the cranial contents, beneath the point percussed. The ordinary percussion note in a healthy child is dull and nearly equally distributed over the vault of the cranium. For distention of the ventricles the note behind the pterion should be compared with the note over the rest of the vault of the skull. It is necessary in the examination that the patient sit up in bed, the head and face being free, and the skull but slightly covered with hair.

A large number of these symptoms are not factors until the later stages of the disease, while many of the earlier symptoms are duplicated in toxic pseudomeningeal conditions. Thus the headache, the opisthotonos, the fever, the petechial and other rashes, the behavior of the reflexes, the Kernig and Babinski symptoms, the rigidity at the back of the neck, etc., some or all may be present in toxic pseudomeningitic conditions, particularly those complicating diseases like typhoid, pneumonia, etc. Fortunately, however, the bacteriological diagnosis of the disease is absolutely distinctive.

For the purpose of bacteriological diagnosis of the disease during life, the meningococcus must be sought for in the cerebrospinal fluid obtained by lumbar puncture. It can be demonstrated by culture and microscopically. Cultures made from fluid obtained by lumbar puncture early in the disease will give positive results in a very large proportion of cases. Betancourt and Franca found it in the Lisbon epidemic of 1900 in 271 cases out of 271 examined. It was found by them in the blood during life. The blood serum of those sick and of those who had recovered had agglutinating properties. In six cases examined by Franca two responded in the proportion of 1 to 100, the remainder one to ten, one to twenty, and one to fifty. Whether the agglutinating reaction will be found to be sufficiently reliable and exclusive to use the method for diagnostic purposes, after the manner of the Widal reaction in typhoid fever, remains to be seen. The diplococcus can also be found in the nasal discharges of patients suffering from the disease, both microscopically and by culture. Weichselbaum, however, quoting Albrecht and Gohn (*Wiener klinische Wochenschrift*, 1901), states that there is some doubt as to the identity of the diplococci found in many of the cases. If lumbar puncture is done early in the disease, a cloudy fluid will be obtained, containing pus cells in which the organisms are found; later in the disease, with a clearer cerebrospinal fluid, the result may be negative. Diplococci are more apt to be found in fluid obtained during the acute stage or during an exacerbation.

When the case is one of toxic pseudomeningitis, the fluid obtained by lumbar puncture is sterile and clear. This, then, is the one reliable and decisive factor in the differential diagnosis of these two conditions. When, however, a cerebrospinal meningitis of the meningococcus type is to be differentiated from a cerebrospinal meningitis of the other bacteriological types mentioned above, subjective and objective, symptomatology is frequently not a decisive aid in the differential diagnosis. It is true that in cerebrospinal meningitis of the tuberculous type, there is generally a longer prodromal period; there is no lucocytosis unless suppurative processes are complicating the tuberculous meningitis; there are more frequently signs of chronic basilar meningitis, resulting in paralysis of the third, fourth, seventh, and bulbar nerves in tuberculous meningitis, while in meningococcus meningitis the opisthotonos is apt to be more marked and more frequent, and yet after all in these various types of meningitis the conclusive differentiating factor will be the finding of the bacteriological organism which is the causative factor in the given case of meningitis. The most frequent organisms giving rise to such meningitis I have already recounted, and upon the finding of these in the fluid obtained by lumbar puncture depends the specific diagnosis.

In a general way the microscopic appearance of the fluid yields some indications as to the bacteriological character of the meningeal process. Thus a purulent turbid fluid speaks for meningococcus cerebrospinal meningitis; a comparatively limpid, clear fluid containing flocculi or fibrinous shreds or a slender white coagulated column, branching out at the top and base like a slender pillar supporting a capital in a test tube half filled with clear cerebrospinal fluid indicates tuberculous meningitis. The diagnosis resting upon such macroscopic appearances, however, rests upon but a slender reed, and to clinch it the bacteria should be found by staining or culture. I must not forget to state that in almost all cases of cerebrospinal meningitis, as distinguished from toxic pseudomeningitis, the normal tension of the fluid in the subarachnoid space is increased, and the fluid issues through the trocar under increased pressure; while this rule is not uniform, it is safe to state that increased pressure indicates an abnormal and not a sterile cerebrospinal fluid.

If this effort has succeeded in indicating the many pitfalls that lie in the path leading to a scientific recognition of meningococcus cerebrospinal meningitis, and if it be true that he who is forewarned is forearmed, then I may hope to have added my little mite to the cause of accuracy in the diagnosis of this disease.

923 Madison Avenue.

Cocoa Supplanting Tea and Coffee.—Statistics lately issued by the Department of Commerce and Labor show that during the last ten years the value of cocoa imported has increased from $1,930,831, in eight months of the fiscal year 1897, to $8,344,426, in eight months of 1907, while the importation of tea shows an increase of only about 10 per cent., and the importations of coffee show an actual decrease.

A PLAN FOR REDUCING INFANT MORTALITY IN NEW YORK CITY.

By WILBUR C. PHILLIPS,

NEW YORK.

SECRETARY OF THE NEW YORK MILK COMMITTEE OF THE NEW YORK ASSOCIATION FOR IMPROVING THE CONDITION OF THE POOR.

The purpose of this paper is to indicate a program by which I am convinced the appalling rate of infant mortality in New York City may be greatly reduced; and if in New York, with all its mixture of races and overcrowding, in any other city where lives are prized and where there are people who will try to save them.

Last year in greater New York 17,437 infants died under one year of age—the majority from preventable causes, due to improper care and feeding. In other words, out of every 100 babies born, fifteen died before they reached the first year of age.* These figures, significant as they are, have been greatly exceeded in many other American cities. In Charleston, S. C., according to the census report of 1900 the mortality rate among infants was 419.5; in Savannah, Ga., 387.5; in Mobile, Ala., 344.5; in Key West, Fla., 311.8; in Biddeford, Me., 311.6; in Atlanta, Ga., 306.0; in Fall River, Mass., 304.7; in Lynchburg, Va., 301.7, and in Richmond, Va., 300.1—a total of nine cities in which the death rate was over 300 per thousand (reported) births. In six other cities, namely: Washington, Baltimore, New Orleans, Philadelphia, Brooklyn, and Boston, the death rate varied from 194 to 274 per thousand (reported) births. These figures, the full significance of which is hard to realize, indicate the position of infantile mortality in our national life. A graphic representation of this fact is given in the following table showing the relation between the deaths of infants from one to five years of age and other individuals of different age groups. (See Charts.)

Infant Milk Depots.—To protect the lives of these little ones, milk depots conducted more or less along the same lines have been established in twenty cities throughout the United States. New York has seven such depots maintained throughout the entire year. Six are owned by Mr. Nathan Straus and the seventh is the Good Samaritan Dispensary, 75 Essex street. Mr. Straus, at an annual loss of many thousands of dollars, generously feeds about 2,000 babies daily. Certified milk is used and is modified according to five formulæ. The bottles are of 3 oz., 6 oz., 8 oz. and 16 oz., respectively. Pasteurization is at a temperature of 167°, maintained for thirty minutes. The milk is dispensed by matrons. Some of the depots feed as many as 400 babies daily. There is no visiting in the homes and the babies are not weighed. One doctor who has general supervision visits each station at regular intervals and consults with mothers who wish to see him.

At the Good Samaritan Dispensary about 200 infants are fed. The milk here is pasteurized in winter and sterilized in summer. Physicians at the dispensary supervise the work. Very simple formulæ are used. The matron in charge puts up the milk in twelve different quantities to suit the age and physical condition of the child. These quantities and the prices asked for them are as follows:

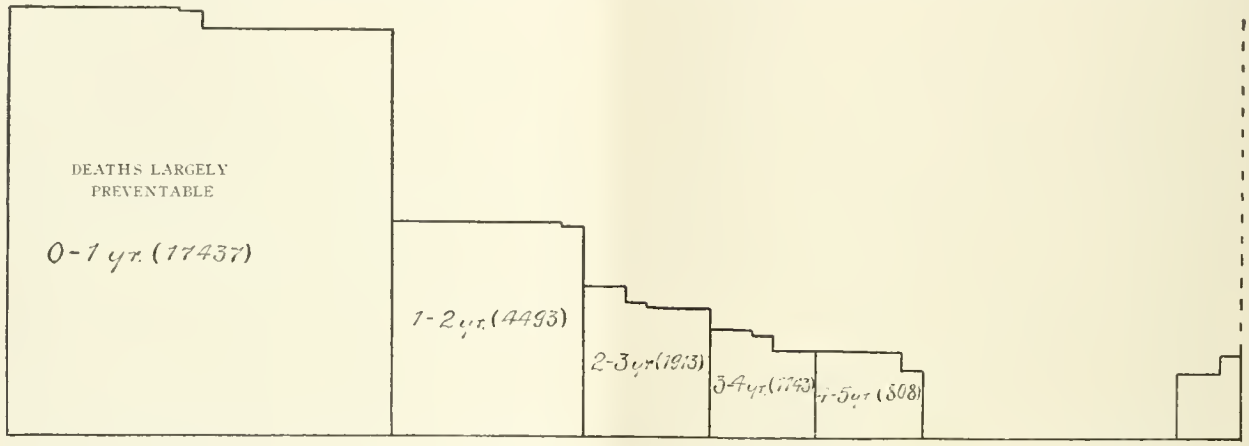

CHART 1.—Mortality in New York City, in 1907, of children under 5 years of age. The total number of deaths in 1907 was 72,205; in those under 5 years, 25,794, over 5 years, 46,411. The square at the right represents the average deaths per year of age of all persons over 5 years of age.

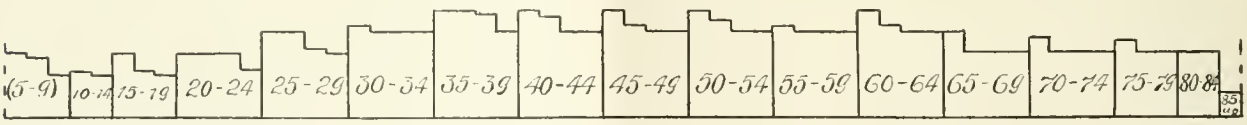

CHART 2.—Average deaths per age for persons of different age groups. The figures in the upper line denote the average deaths per year for each group; those in the lower line denote the total deaths in each group.

Age of Child			Quantity of Milk		Price Paid by Consumer
Days	1 to 3		½	ounce	½c
"	3 to 6		1	"	½c
"	6 to 14		1½	"	1c.
Weeks	2 to 4		2	"	1c.
"	4 to 6		2½	"	1c.
"	6 to 8		3	"	1c.
"	8 to 12		3½	"	1c.
Months	3 to 4		4	"	1½c.
"	4 to 5		5	"	1½c.
"	5 to 6		6	"	1½c.
"	6 to 7		7	"	2c.
"	7 to 8		8	"	2c.

Last year at the close of the season the Good Samaritan Dispensary showed a balance on hand of $131.23—this in spite of the fact that the plant is the oldest in the city and employs methods which have been commercially improved upon.

In addition to these stations the Diet Kitchens Association, a charitable organization, supports sev-

*This of course is an average estimate. In well-to-do families babies die rarely—not more than one or two to every hundred born. In crowded sections this rate leaps up to twenty, thirty, forty, or even fifty per hundred, according to the temperature, poverty of the parents, home conditions, etc.

en depots with matrons in charge who dispense free of cost raw milk from cans to babies and invalids. Matrons serve the milk in the morning and visit their beneficiaries in the afternoon. Mr. Straus also maintains ten summer depots located in parks and at recreation piers.

In Brooklyn the Children's Aid Society dispenses pasteurized modified milk for seventy-five days in the summer from fifteen depots. This is done under the supervision of physicians. The rent of all but one of these depots is furnished free by churches, settlements, and other organizations. Matrons divide their time between dispensing milk and visiting in the homes.

Education as a Means of Reducing Infant Mortality.—The point I wish to emphasize in connection with these depots and with all other depots patterned after them, is the absence of any organized educative effort in connection with the dispensation of the milk, and especially the lack of sufficient emphasis placed upon the importance of breast feeding, which of itself is the greatest of all remedies to prevent infantile mortality. These matters it seems to me have not received sufficient emphasis by those dealing with the subject of infantile mortality in this country.

In France wonderful results in lowering the death-rate of babies have been obtained through education alone not connected, in a majority of cases, with the distribution of milk. The plan adopted is that of the Consultations de Nourrissons, consisting of weekly classes or clinics where babies are weighed and where mothers listen to talks by volunteer physicians on the preparation of milk and the feeding and care of their little ones. The main essentials of this plan, according to the founder, the late Docteur Budin, are a pair of scales and the services of a devoted physician. The main thing striven for is the encouragement of breast feeding. Where this is impossible, the mother is taught to sterilize or pasteurize the milk, of which exact quantities are prescribed. A Secretary to keep record of the weight and physical progress of the babies either volunteers her services or is paid a slight fee. At each weighing the doctor points out in what way the mother has succeeded or failed in following his instructions of the week previous. By blaming some and praising others he thus stimulates a keen interest which is increased by a spirit of natural rivalry among the mothers.

Because of the keeping of individual records, the results obtained by these consultations are directly available. In 1898, for example, the death-rate from diarrhea at Paris during certain weeks was as high as 250, 275 and 285. At the consultation of the Clinic Tarnier, out of a total of from 90 to 140 infants who assisted there, not one infant died from this disease. This was repeated in 1899, 1900, 1901, 1902 and 1903. During a period of ten years at this clinic, only one infant died from gastroenteritis, and this death was due to the headstrong disobedience of a mother who refused to follow the instructions of the physician in charge.

In the Department of Yonne out of a total of 1,935 infants only 56 deaths, or 2.89 per cent., were recorded.

At Appoigny, of 69 infants which followed the Consultations from 1902 to 1905, three, or 4.34 per cent., died, whereas of 9 infants which did not follow the Consultations 4, or 44.4 per cent., died.

At Toucy the mortality rate for infants before the establishment of the Consultations was 197.3 deaths per 1,000 births. The first year after the establishment of the Consultations it had decreased to 120 and the second year after to 50.5.

At Villeneuve-sur-Yonne the mortality rate before the establishment of the Consultations was 163. In 1904 after their establishment it had decreased to 82 and in 1905 to 32. Of 60 infants whose mothers assisted at the clinics during 1904 only 4 died and of 94 infants in 1905 none died. The mortality rate at the Consultations for these two years was respectively 66 deaths and no deaths per thousand births.

At Sens the mortality rate before the establishment of the Consultations was 116. In 1904 after their establishment it had decreased to 80, and in 1905 to 47. Of 72 infants whose mothers assisted at the Consultations in 1904 only 1 died, and of 176 infants in 1905 only 2 died. The mortality rate at the Consultations for these two years was 14 deaths and 26 deaths respectively per thousand births.

At Auxerre the mortality rate before the establishment of the Consultations was 205. In 1904 after their establishment it had decreased to 120 and in 1905 to 60. Of 143 infants whose mothers assisted at the Consultations in 1904 only 2 died and of 182, in 1905, 5 died. The mortality rate at the Consultations for these two years was 13 deaths and 27 deaths respectively per thousand births.

At St. Pol-sur-Mer during a period of 5 years before the establishment of the Consultations the mortality rate was 288. In 1903 after their establishment it had decreased to 209 and in 1904 to 151.

The value of statistics *per se* is illustrated in the above lessons.* Having these figures, each physician is able to compare the mortality rate among his own infants with those of his township, of his department, of his country as a whole. Following are given percentages showing the comparative mortality rates before and after the establishment of consultations in some of the small communes, together with the number of infants which attended these consultations:

	Before the Establishment of the Consult., 1898–1904	After the Establishment of the Consult., 1905	Before the Establishment of the Consultations 1898–1904		After the Establishment of the Consultations 1905	
	Death Rate per 1,000 Births	Death Rate per 1 000 Births	Infants Born	Infants Died	Infants Born	Infants Died
Avallon	100	58	637	64	103	6
Connerre	66	70	437	29	57	4
Bléneau	61	0	327	20	42	0
Quarré-les-Tombes	90	52	386	35	32	2
St. Bris	103	0	233	24	25	0
Rogny	70	27	200	14	26	1
St. Cyr-les-Colons	112	0	98	11	11	0
Grampignelle	67	47	206	14	21	1
Héry	40	0	175	7	33	0
Monéteau	74	0	162	12	25	0
Pont-sur-Yonne	126	93	316	40	32	3
Augy	180	0	61	11	10	0

These facts are enough to prove the value of education not connected in any way with the distribution of milk.† In urban communities where pop-

*The lack of statistics in our American depots makes it impossible to ascertain what actual effect they have had in reducing infantile mortality. An argument has thus been lacking which would prove of value in a wide extension of this needed work.

†The milk used on the continent is rarely modified.

ulation is congested and clean milk difficult to obtain the combining of a milk depot with one or several consultations makes an ideal arrangement; but the operation of depots which dispense milk without any carefully conceived plan of educating mothers in the use of it, or in the care of infants, is one which holds itself open to criticism. Undoubtedly the strongest argument against such depots is that by making an artificial food cheap and easy to obtain they tempt mothers to hand feed instead of breast feed their babies. Dr. Pinard and Dr. Peyroux in pointing out this danger state that the leaflets, directions, and other literature circulated among mothers, most of whom are uneducated, operate against the natural process of breast feeding and often produce pernicious effects. This fact is important when one considers the many other causes such as ignorance, poverty, economic conditions, etc., which operate to prevent mothers from suckling their children.*

In the work of the Association for Improving the Condition of the Poor, under which the New York Milk Committee is organized, cases are frequently reported where mothers a week or so after the birth of their child are up and about looking for work. These mothers often put the baby "out to board" or leave it with its big sister or some other persons whose selected diet consists very likely of baked potatoes, tea, crackers, candy, sugar sops, anything that is cheap and sweet. Sometimes, to be sure, the employment of the mother is an economic necessity. In such cases the interests of humanity demand that society shall step in and assist her. On the other hand, breast feeding in a great many cases is economically possible if its importance is realized, and the ratio of mortality rates among breast fed and artificially fed children shows that in such cases artificial feeding is highly reprehensible. Dr. H. Helle's investigations on this subject are too well-known to be more than touched upon. Of 170 babies who died of diarrhea in Graz, in 1903-04, Dr. Helle discovered that only four were breast fed, forty-eight were partly breast fed, and one hundred and seventeen were bottle fed. In Finsbury, England, Dr. Newman carried on a similar investigation among the English and Italian families in the Italian quarter. The English infants who were hand fed he found died at the rate of 295 per thousand births in 1901 and 242 per thousand births in 1902. The Italian infants who were breast fed died at the rate of 106 per thousand births in 1901, and 192 per thousand births in 1902.

From 1884 to 1886, Dr. Hope carried on an investigation in Liverpool, England, which demonstrated that of infant deaths under three months of age the number of babies wholly or partially hand fed who died was fifteen times as great as the number who were breast fed.

Of 1,000 babies under three months of age he found that 20 breast fed died of autumnal cholera against 300 hand fed. The comparative mortality among breast-fed and artificially-fed children in Berlin is equally striking.

*No exact figures as to the number of mothers among the poorer classes who nurse their own children in New York City are available. Dr. Holt estimates the percentage who are *physically able* to do so as from 75 to 90 per cent. On the other hand, he states not more than 10 per cent. of the well-to-do mothers nurse their own children through the entire period of infancy; 20 per cent., perhaps, nurse them throughout the first six months, and 25 per cent. nurse them throughout the first three months of life. These facts are extremely interesting, considering the high mortality rates in congested districts.

Year	Number of Deaths of Infants Where Method of Feeding Was Ascertained	Number Breast-fed	Percentage Solely Breast-fed	All Others
1900	9,538	895	9.36	90.64
1901	9,338	856	9.17	90.83
1902	7,027	768	10.90	89.10
1903	7,680	723	9.41	90.59
1904	7,780	753	9.68	90.32

In Derby, England, Dr. Howarth investigated the feeding of 8,343 infants. He found that the breast-fed babies had much more resistance than the hand-fed babies with respect to diarrhea, and that even bronchitis, pneumonia, and similar diseases carried off 12 per cent. more hand-fed and therefore less resistant babies than breast-fed. Dr. Howarth's total figures indicate that the infant mortality for hand-fed infants was three times greater than that for breast-fed infants, although the social environment and housing conditions were if anything rather better for the hand-fed.

These facts are startling and show that milk depots from which a substitute for mother's milk is sold defeat their own purpose if they neglect to make clear that this milk is only a substitute for mother's milk, not to be used except as a last resort when the mother is absolutely unable to suckle her own child. That breast feeding can be helped and encouraged has been strikingly illustrated in France.

At Varengeville before the establishment of the Consultations des Nourrissons not a single mother breast fed her own child. At the end of the first year the percentage of breast-fed children was raised to 47.5 and at the end of the second year to 75 per cent.

At Saint-Pol only 22 per cent. of mothers breast fed their own children before the establishment of the Consultations; at the end of the first year the percentage was raised to 35 per cent. and at the end of the second year to 77 per cent.

At Dr. Bresset's Consultation in the rue St. Dominique in Paris only 40 per cent. of mothers breast fed their own children before the establishment of the clinic; at the end of the first year the percentage had been raised to 63 per cent. and at the end of the second year to 81 per cent.

Before the establishment of Dr. Bresset's Consultation in the rue Oudinot 61 per cent. of mothers breast fed their own children; at the end of the first year this percentage had been increased to 67 per cent., and at the end of the second year to 71 per cent.

The close relation between the increase in the number of breast-fed children and the decrease of infant mortality indicates the true responsibility of a milk depot. In its normal development it should sell less and less modified milk to babies and more and more whole milk to mothers: becoming ultimately a clean milk depot from which food is fed through the mother to the child.

Need of Corporations.—Having made these facts clear—the importance of education, particularly with reference to breast feeding—I wish to outline the plan which I have in mind for reducing infant mortality. Before doing so, however, one thing should be emphasized. In the twenty cities throughout the United States which possess infants' milk depots, sixteen systems are supported by philanthropy and four by the municipalities themselves. As far as I know no successful effort has been made to provide, through the framework of established business, a modified milk for infants at prices which the poor

can pay. Physicians, philanthropists, and, it may be, health authorities have failed to cooperate with or, indeed, justly to appreciate the experience and competence of those who often have dealt for a long time and in a most practical manner with problems which they themselves may have but recently become interested in. In fact, cooperation in the broadest and best sense of the word has been lacking to a marked degree in the milk situation, and it is only through this cooperation that milk can be improved and infant mortality can be reduced in our American cities. In Manhattan and the Bronx alone there are nearly 5,000 physicians of all nationalities, 606 churches, 45 settlements, 52 day nurseries, 35 hospitals for women and children, not to mention other organizations, which give more or less time and attention to the problem of family life, especially as it affects infants and young children. Many of these institutions already have organized classes for mothers; many of them employ trained nurses either for field or dispensary work; many have medical supervision. Splendid opportunities are here presented for assisting in the work of reducing infant mortality. It cannot be done by the Health Department or physician alone, nor yet by the church, social or charitable worker. Neither can the milk dealer who is frequently as generous as any, but who lives by the proceeds of his milk, be overlooked. All must contribute. No one must work in isolation. A definite goal must be set, and all must cooperate in reaching it.

Plan for Reducing Infant Mortality.—This leads me to the first and fundamental part of my plan for reducing infantile mortality, namely: the establishment on a large scale of consultations on infant hygiene (I choose this name because it seems to me the word nourishment is not sufficiently inclusive) in New York City. These consultations could be organized in a simple, inexpensive manner, after the pattern of the Consultations des Nourrissons in France. Their object should be: (1) The education of mothers in the care of babies up to the age of two years; (2) the encouragement in every way of breast feeding; (3) the education of mothers in pasteurizing, sterilizing, and modifying milk in the homes.*

Groups of twenty or twenty-five mothers could be collected and the clinic or consultations held in churches, settlements, day nurseries, and other similar institutions.

In this work the enthusiasm and unselfish cooperation of physicians is essential. Technical differences of treatment should be set aside and every effort centered on inculcating recognized fundamental principles of hygiene.† To economize time and effort two or even more physicians might work together in the same class, giving, say, one hour of the week, or one hour every other week, for a fixed group of infants. The necessary equipment for these clinics is extremely simple, consisting, as I have already pointed out, of a pair of scales and the devotion of those in charge. Babies should be weighed weekly at the consultation. In attending these consultations, mothers would be stimulated not only by the desire to exhibit their own babies but to see the babies of their neighbors and to compare data concerning them. Each baby would be stripped and examined in the presence of all the mothers; an opportunity thus being given the doctor to make a practical illustration of the lesson which he wishes to teach. A spirit of rivalry could be created by holding baby shows with prizes for the best babies. Volunteers to act as secretaries for the physicians could easily be obtained from the institutions where clinics would be held. The secretary would keep weights and statistics of the babies. Charts showing the natural and actual increase in each infant's weight should be kept and shown to the mother as an incentive to care properly for her child.

At first, naturally, mothers would be slow in coming to the consultations. Later, however, the work would surely become recognized. Women who, at first, looked upon the clinics with disapproval would, as experience has shown repeatedly, find that their babies did badly or perhaps died, whereas babies whose mothers attended regularly did well. The consultations would thus become talked of in the neighborhood and would gradually take their places as permanent educational institutions.

For the sake of record, all charts, tables, etc., should be kept uniform and it would be well also if the scales used were of the same make.* A central clearing house thus becomes necessary, and I should suggest in the absence of any other agency that the New York Milk Committee, which is planning to open seven milk depots and to establish a number of consultations of its own this summer, be drawn upon in this matter. A nominal fee might be asked for the charts and tables in this case. By being able accurately to calculate the annual mortality rate in infants under their supervision and to compare this rate with the mortality rate of the city and of rival consultations a helpful spirit of competition would be created among the different physicians.

As far as the milk itself is concerned the problem is not so difficult as it seems. Existing organizations from which a modified milk for infants is sold should be encouraged and patronized. Where such depots do not exist the New York Milk Committee, in so far as it is able, will endeavor to establish new depots throughout the coming year; and where the establishment of new depots is impossible, milk dealers should be called upon to provide, especially for infants under two years of age, a special supply of clean milk which I am not at all certain they would be unwilling to sell at cost, especially during the hot summer months. The milk dealer, in other words, will be no slower to cooperat in this movement than will be the physician, the

*The question of home refrigeration should demand careful attention at these consultations, for, no matter how safe the milk is when it leaves the depot, a few hours in a broiling sun are sufficient to render it unfit for the baby's stomach. This point so far has been neglected in feeding tenement babies. The construction of inexpensive refrigerators or sawdust and paper boxes in which milk can be kept in water at a low temperature should be taught and everything done both in a suggestive and practical manner to safeguard the milk after it reaches the home.

†It would be well in this connection if some of the older physicians who are giving especial attention to infant feeding could supervise and direct the younger men. Meetings for this purpose might be held from time to time. A general conference on infant mortality called before the hot weather sets in would be timely.

*Uniform printed instructions to mothers are also greatly needed in New York City. At present mothers frequently receive as many as five or six different sets, issued by various hospitals, dispensaries, settlements, milk stations, etc. These sets confuse, whereas one set sent repeatedly would drive the message home. Simple uniform instructions, printed, say, by the Health Department and distributed to mothers through milk dealers, as well as other agencies, would greatly help in the progress of education. In this the newspapers—especially newspapers printed in foreign languages—could cooperate.

social or charitable worker, or the public citizen.*

Meanwhile, for babies whose mothers are ignorant and who live in sections where everything militates against their lives, the establishment of new infants' milk depots cannot go on too quickly. To enlarge the field of existing depots the New York Milk Committee has arranged with one of the best-equipped milk dealers in New York: (*a*) To supply it at cost with any quantity of certified or inspected milk which it may desire. (*b*) To modify this milk according to formulæ for infant feeding. (*c*) To bottle it in "feedings" suitable to the age and physical condition of the child—one "feeding" to each bottle. (*d*) to dispense milk from two of its regular stores under the supervision of the committee's nurses. (*e*) To provide and deliver as much certified or inspected modified milk for infants as the Committee wishes, provided depots can be secured from which to dispense it. No modified milk will be sold to any depot except through the Committee.

Modification will be in the company's laboratory under the supervision of a doctor and bacteriologist. From this laboratory or central plant the milk will be delivered to the distributing depots. Orders for "feedings" will be sent in at the close of each day from the depots to the laboratory, where the milk will then be prepared for the following day.

A price will be asked for the milk low enough to place it within reach of the poor, yet high enough to prevent a financial loss on the part of those handling it. This price will be fixed by the New York Milk Committee, which will charge each depot for the milk and render bills for the same. The prices will be patterned after those of the Good Samaritan Dispensary.

Three-ounce, six-ounce, and eight-ounce graded sterilized bottles will be used. They will contain exact "feedings" for individual babies. Nipples will be directly adjustable. Deposits on bottles will be required to cover loss in case of breakage. Washing and sterilizing of bottles will be done at the central plant.

On June 15 the Committee will open seven new infants' milk depots. Each of these depots will be in charge of a trained nurse who, in addition to dispensing the milk, will act as secretary at the Consultation and, by house-to-house visiting, will endeavor to stir up interest in the work throughout the neighborhood. Already many settlements, churches, and day nurseries have volunteered assistance. A number have offered rooms for use as depots and all without exception have offered the use of their quarters for consultations on infant hygiene. In localities where existing depots already dispense milk, the mother will thus receive instructions at the consultation, and milk at the depot.

In establishing new depots the cooperation and assistance of the public may fittingly be added to that of the physician, the social worker, and the producer of milk. Where rooms cannot be obtained free of rent the cost of establishing depots in charge of trained nurses from which 100 babies can be fed under the supervision of a physician is as follows:

Minimum		Maximum	
Rent (at $20 a month)	$ 240	Rent (at $25 a month)	$300
Salary of nurse	900	Salary of nurse	900
Initial cost of painting, white-washing, etc.	50	Initial cost of painting, white-washing, etc.	100
Equipment (table, chairs, refrigerator, scales, etc.)	65	Equipment (table, chairs, refrigerator, scales, etc.)	100
Fuel and light	20	Fuel and light	30
Incidentals	25	Incidentals	70
Total	$1,300	Total	$1,500

It is hoped that at the end of the first year the proceeds on the sale of the milk will (especially in depots the rent of which is supplied free) pay all or part of the nurses' salaries, together with the running expenses of the station. The practicability of this remains to be demonstrated. By its arrangement with the milk company the Committee furnishes bottles, crates, bottle fillers, and other new equipment.

In addition to the depots which it will establish, the Committee will also place three nurses in the field, whose duties will be simply that of organizing Consultations on Infant Hygiene in different neighborhoods. In this way it is hoped some comparative idea will be gathered of the results obtained at Consultations connected and unconnected with the dispensation of modified milk.

The plan above outlined, except as it concerns the establishment of milk depots, is applicable to any American city. Its chief and essential element is cooperation. In cities of smaller size than New York, the question of obtaining a clean milk is simplified; and, because of the less complex conditions of life, instructing mothers how to prepare and care for this milk in the home is rendered much easier. With this instruction, even where it is impossible to establish infants' milk depots, a striking reduction of infantile mortality can, I feel sure, be realized.

*The association for the improvement of the milk supply of New York, an organization of milk dealers, of which Dr. Ernst Lederle, former Health Commissioner, and a member of the New York Milk Committee, is an active member, could be drawn upon in this matter. Mr. Loton Horton, president of this association, has also recently been elected by the association a member of the New York Milk Committee.

THE CORRELATION OF EYESTRAIN AND THE FUNCTIONAL NEUROSES.*

By HOMER E. SMITH, M.D.,
NORWICH, NEW YORK.

In accepting the invitation to read this paper I feel not only a keen appreciation of the honor done me, but also of how inadequate must be any presentation of this subject within any reasonable time-limit. Any of its technical phases would here be out of place, so let us look at this matter as a whole and from the viewpoint of the general practitioner. It is unfortunate that the term "eyestrain" has become so firmly fixed as the designation of this condition, for the symptom-complex which goes by that name is not eyestrain at all. We do not see with our eyes any more than we hear with our ears; etheric and atmospheric vibrations are conditions of matter, light and sound are their cerebral manifestations. The muscular mechanism which brings the light rays to homologous points upon the retinæ and *holds* them there may become fatigued, the cerebral centers which receive these impulses may become exhausted, but the eye itself suffers no strain. It may become damaged, it is true, but this is consequent and secondary to the congestion of the organ incident to improper functioning. It would be difficult to frame either a word or a phrase which would express with accuracy either the causes or the results of eyestrain. "Neurasthenia" does not do it, for it is not a weakness of the nerves; "myasthenia" also fails, for the muscles are not wanting in power. A single term

*Read before the Tioga County Medical Society, March 3, 1908.

cannot cover several causes, nor a single term embrace multiple effects. Let us hold in mind, however, that, at the last, it all comes back to this—an overdraft on the Bank of Neuricity; an overdraft from the fount of neural flow. The latter analogy is perfect. If the demand from the fountain and the reservoir connected therewith be greater than the supply, then will soon ensue exhaustion. In the body we have a reserve store of nervous energy, from which we may draw; the loss by day is made good during sleep, but if the drafts on this reserve be excessive, then only can result one thing—nervous exhaustion. It should be clearly understood, in speaking of eyestrain, that it comes not from lack of contractility in the muscles nor from failure of neurility, but from overwork of the specific cerebral center which presides over the particular muscle or group of muscles at fault working under just surmountable difficulties.

Let me call your attention briefly to the anatomico-physiological aspect of the function of binocular vision. In the first place, the retinal impression must be transmitted to the brain and there resolved into its component parts of light, form, and color. There are separate centers for each of these, and they are linked, cell for cell, with their fellows in the other half of the brain. Inequality of refraction between the two eyes must cause unequal stimulation of these conjugate centers, and confusion results. In fact, if the ocular dissimilarity be very marked the mental disturbance will be so great that either one eye will, more or less, go out of function or there will result a dissociation of the conjunct centers and loss of binocular vision. We are the sum of our experiences, and will, judgment, and other attributes of personality are simply syntheses of sensory impressions. How necessary, how essential in fact, does it become that this avenue of our most important sense shall convey accurate impressions to the brain, even should no discomfort result in the transmission? Unequal refraction results in disturbed binocular fusion; imbalance of the extrinsic ocular muscles produces difficult or impossible binocular fixation, and accommodative disablement, in proportion to its degree, causes, in the hyperope, painful or blurred vision for all distances, in the myope these only within his far-point. The eyes are moved in the orbits by six little muscles attached to the globe and arranged in pairs. For the simplest movement at least four must be energized; for the more delicate adjustments the whole twelve may be called into play. More than this, for function in convergence two of these muscles must receive an added neuricity. How exquisite must be the coordination of these little muscular bands which enables us rapidly to alter fixation from near to distant things, and which links with it an accurate focus on the object seen. Binocular vision and accommodation were the last two products of evolution, and being the last developed, are least established as a racial habit and are the easiest to lapse out of function. The dissection of a thousand eyes will show how marked are the variations in the muscular attachments, and consequently how often may result impairment of action.

The most important of the ocular muscles, the ciliary, lies within the eye and presides over the function of accommodation. By what mechanism it fulfils its purpose is still a matter of controversy. The authority of Helmholtz has carried such weight that his theory has been almost universally accepted. I cannot accept it, for, if it be true, there must be a constant traction on the zonula when the eye is adapted for distance. This implies action in a state of repose. The terms are incompatible. In accommodation for small distances within the working point there must be a passive action, due to the inherent elasticity of the lens capsule. This is in contravention of the rule of actor and antagonist in exact coordinate movements elsewhere in the body. Furthermore, the question at once suggests itself, What exerts the traction on the zonula to keep the lens adapted for distance? Whatever may be the action, it is difficult to understand in the normal eye, in an astigmatic one, next to impossible. Nevertheless, to my mind, astigmatic accommodation does exist and is possible within limits, say up to one-half diopter, and it is just this onerous and difficult functioning that makes so disastrous small degrees of astigmatism. Arranged in their order of relative importance and frequency there are refractional, accommodative, and muscular causes of poor, difficult, or painful vision. These errors may all be coexistent, and yet the patient may not suffer from any reflex disturbances; one only may be present and the most serious consequences ensue. This sounds paradoxical, but let us analyze it a little closer. Let us take, for example an individual who has in each eye a simple myopia of three diopters. Such a person has a far-point of distinct vision at thirteen inches only. Beyond that, everything is blurred and out of focus. He has poor vision, but, barring muscle-imbalance or intraocular disease, he will never suffer from painful vision nor will any reflex disturbances ever result. Occurring in his early years, it condemns him to a solitary childhood, to introspection and morbidism, to an ill-developed body, and to early disease, but it does not damage his nervous balance. On the other hand, an hyperope, proportionate of course to his years and the amount of the hyperopia, has good distant vision, but this is secured only by constant tension of the ciliary muscle, and for nearby, still greater efforts. If sustained near-work is compulsory, this individual will suffer from accommodative asthenopia, painful vision, and perhaps some of the reflex neuroses which will be mentioned later. This condition always occurs in childhood; in fact, it is congenital and developmental. Such children are behind in their studies, truants from school, usually robust in body but mentally ill-developed, acquire bad habits, and are promising recruits for the criminal class. An astigmatism, if of high degree, is worse than either of these other conditions, for by no effort can good vision be obtained either for distance or near. Notwithstanding the resultant poor vision, its evil effects, aside from its repressive influence on mentality, are expended on the eye itself. Choroidal and other intraocular diseases develop, but neurotic or other reflex disturbances do not follow in its train. It is the moderate degrees of hyperopia, and the astigmatism which may just be neutralized by ciliary effort, which work such havoc, and which give rise to remote and damaging reflexes. It is for just this reason that the State examination of the eyes of school children fails in its purpose. It is not the child with poor vision that is to be pitied; rather is it the one who sees the clearest. More than one-third of the children of school age have visual disturbances sufficient to hamper them in their work; others, just enough refractional error to undermine the health and upset the nervous equilibrium. It should be the advice of every family physician to the parents that they have the eyes of their children examined under atropine before permitting them the onerous ocular labor which modern schoolwork entails. Almost

never has the patient poor vision who comes complaining of headaches, and it is the rule that the disturbances due to eyestrain are in proportion to the visual acuteness. It is the little errors which cause the mischief, and it is an easy matter for a poor refractionist to convert an unirritating ametropia into a most exasperating error through slight over- or undercorrection. A patient with two diopters of astigmatism has the focal line so far in front or behind the retina (according as the error is myopic or hyperopic) that vision is greatly reduced; throw that focal line nearly but not quite on the retina and trouble immediately begins. Sight, of course, is greatly improved, but the ciliary muscle, in the interest of still clearer vision, gets in its fatal work, and during every waking moment is striving for the impossible, with the sure result of a nervous drain which somewhere will show its effects. It is evident, or at least I have tried to make it so, that the final and ultimate result of uncorrected ametropia expends itself as loss of neuricity. If you give yourself an artificial hyperopic astigmatism by weak minus cylinders, or a hyperphoria by a base-down prism placed before your eye, there will result in a short time nausea, headache, and vertigo; not due in this case to nerve exhaustion, but to a disturbance of the nice balance between conjugate and correlated cerebral centers. This is acute. The chronic drain, due to congenital defects, leaves an insufficient supply for other vital processes, and its effects may be manifested anywhere in the body along the lines of least resistance. If you grant these premises, which personally I know to be true, then you must admit the conclusion that from eyestrain any functional disturbance is possible anywhere in the body.

The foregoing has been somewhat technical, but only enough so to make clear the far-reaching effects of this cause of neural loss. Let us now see wherein lies its practical application in general practice. Let us take, for example, a patient with chronic, intermittent headaches, the most common manifestation of eyestrain. He would be a most bungling and culpable practitioner who would prescribe for this symptomatically. The trained physician would make a uranalysis when the presence or absence of albumin or indican would give him clues of value; if necessary, he will have made a blood-count; he will take a careful history, and give due weight to neurotic conditions. Habits of life, conditions of the skin and bowels, or menstrual disturbances may all be factors in the case. Not every possessor of an error of refraction suffers from eyestrain. The ditch-digger may have an astigmatism of one-fourth or four diopters and never know he has it. To render it disastrous, there must be brain-work and eye-work combined, and in proportion to these will lesser sources of local irritation operate to induce the more disturbing reflexes. Not even neuroticism and astigmatism in combination will always give rise to a nervous débacle; there must also be more or less prolonged near-work for the eyes. Our bodily functions are so linked together that disturbance of one reflects on the other. We may have ocular palsies from a decayed tooth, or cough from impacted cerumen in the ear, or epileptiform seizures from pinched nerve-ends in an old scar. The profession recognizes all these, but it refuses to recognize that a constant, wearing strain on the ocular structures can result in remote disturbances. Nevertheless, it does, and paroxysmal headache is the most common of these; but there may be anorexia, heartburn, nausea, and vomiting as the gastric reflexes; menorrhagia, dysmennorhea, or amenorrhea as the uterine disturbances; or chorea, insomnia, nocturnal enuresis, and epileptiform attacks as nervous anomalies caused by eyestrain. There is besides all these that obscure group of symptoms which is generalized in the term "neurasthenia." Causeless weeping, melancholia, exhaustion of mind and body, inability to fix the attention are some of its protean manifestations. Mind you, I am not saying that all these things have for their sole and underlying cause an error of refraction, but I do insist that, given this error, a neurotic diathesis and eye-work combined, you have as pretty a combination for trouble as one could wish for.

In investigating any bodily ailment we would naturally seek first for its most frequent cause; later, the more infrequent. In typical migraine the eyes are in fault in 95 per cent. of these cases, perhaps more, but so nearly certain is this the case that I have little hesitancy in promising a cure, and none in promising relief. Migraine is a more or less severe paroxysmal headache, often unilateral, but not always so, associated with nervous disturbances, nausea, or vomiting. There may be forewarnings of the attack in ocular symptoms, transient hemianopsia or scotoma scintillans, or in reflex disturbances of sensation in the neck and arms. The term "sick-headache" fits it better than the pseudo-scientific one of migraine, and there are none of you who have not seen it many times. Have any of you ever cured it by drugs? To every skilled refractionist the cure is so nearly a matter of course that it ceases to have any interest for him. This is a pity, too, for he should drive this truth home, in season and out. This which is so matter-of-fact to him is to many not even known. The neurologist, the gastrologist, and the gynecologist have all advanced their hypotheses as to the etiology of migraine, but they all fail to explain why the condition comes on with the advent of school-life and disappears with the coming of old age. Only accommodative strain and loss of accommodation can be factors incident to these widely-separated intervals; organic disease is too early for the one and should have reached its climax in the other. It should be borne in mind, however, that not always is disease cured by removing its principal cause, for there may have grown up associated maladies, or other factors may complicate the case, but it may be safely said that 99 per cent. of sick-headaches may be cured in the young, and 90 in the middle-aged: old people do not have it.

If what has been advanced is true, namely, that overdraft of energy through one channel leaves others unsupplied, then it need cause no surprise that reflex neuroses anywhere may result from the enormous drain that eyestrain imposes on the central nervous system. In closing this phase of the subject, let me leave with you this suggestion: If you have a patient who presents evidences of disturbed function anywhere in the body with no organic lesions to account for it, you have not done your duty to that patient until the possible ocular origin of this has been determined. Headache, while the most common, is not the only manifestation of eyestrain; neuralgias, anesthesias, and paresthesias are sensory disturbances: bradycardia and tachycardia, heart symptoms; recurrent rhinitides and spasmodic asthma are evidences in the respiratory tract; gastralgia, dyspepsia, anorexia, nausea, diarrhea or constipation are functional disorders of the digestive apparatus; menstrual and ovarian disturbances may be due to this cause; night-terrors, insomnia, nocturnal enuresis, epileptiform seizures,

and that multiform neurosis which is termed neurasthenia, all may have their origin from or perpetuation by uncorrected visual anomalies. Pardon this repetition, but I want to drive home the conviction that there are other disturbances besides headache due to eyestrain. You don't have to advise a patient with headache to go to an oculist. The people have found that out for themselves, but this advice would come from you with much better grace. Remember that reflex disturbances are possible anywhere. The term "neurosis" means a neural disability and eyestrain, even if it be not the causal, may be a contributory factor; and this source of nervous leakage should be stopped.

An eminent ophthalmologist has stated that there are seventy-eight reasons why glasses may have failed to give relief. These might be summed up into one—the glasses did not fit. By this is meant lenses and frames together. Not one of these seventy-eight factors may be safely neglected if good refraction work is to be done. It is not within the scope of this paper to review the difficulties which underlie this work, nor to discuss the many causes of failure. Two things are certain: that nothing in all medicine approaches it in difficulty, and that to entrust this work to the optician or the careless refractionist is simply to invite failure, or to make a bad matter worse. Would you send your pathological specimens to the maker of microscopes, or invite your druggist to prescribe for your patients? You do worse when you tell patients with eyestrain symptoms to go to the jeweler and get a pair of glasses. In the first place the law does not permit him to use atropine or other cycloplegic, and without it scientific refraction work is impossible. Remember, too, that the glass which is nearly but not exactly right is worse than none at all. The oculist who works without a mydriatic, and who cures his patients by taking off their glasses, belongs in the jeweler class and is in training for the High Priesthood of the Has-Beens. Don't, in the name of common-sense, send your case, unless, perchance, it happens to be a watch-case, to the watch-maker, nor, when the result is a failure, conclude that eyestrain had nothing to do with the symptoms. Don't trust an oculist either who does the work in one short visit, who works without a cycloplegic, who corrects only the manifest error, whose cylinder-axes come out beautifully in even numbers, who thinks a quarter diopter the smallest cylinder in the trial-case, whose spheres run in half diopters, or who thinks small astigmatic errors of no importance. It is in just the little things that lies the difference between success and failure.

The thought which has been uppermost in mind throughout the foregoing has been refractional errors, but it should not be forgotten that there are other ocular conditions which give rise to eyestrain. Imbalance of the ocular muscles, in a small proportion of the cases, is a source of irritation from which may start reflex troubles. That a large number of these are refractional and innervational in nature is surely true, but it is equally certain that there exists intrinsic imbalance, due to faulty implantation of the tendons on the globe, and when this is the condition, only well-studied and carefully-executed surgical measures will give relief. A most frequently overlooked source of eyestrain is crippled accommodation. The age of the patient is no criterion for this failure. There is no rule for presbyopia. It may come in early years, or be long delayed beyond the classic 45 of Donders. More than this, it may be unequal in the two eyes. There is nothing astonishing in this; patients with unequal refraction must accommodate unequally if they are to obtain binocular fusion, but it is noteworthy that even when the static refraction is made equal by glasses there sometimes remains a difference in the accommodative power, and not infrequently the eye which before was using the most for distance now has less in reserve for close work.

There are many causes of failure to relieve where glasses have been prescribed; a few of the more common ones will be here briefly set forth, so that when the patient whom you have sent to the oculist is not benefited, you will perhaps better appreciate that the trouble lies, not with the method, but in its application. In the first place—and this is true, first, last, and all the time—no cyclopegic, no refraction. That any argument should be needed on this point is astonishing, yet there are near-oculists who work without it, and the jewelers have to. Anyone who accepts a pair of glasses without this procedure does so at his own risk. Any so-called oculist who so prescribes them is a wretched bungler and culpable to boot. It is worse than a crime, for it may, for the patient, shut the door on good health, good living, and good fortune. Therefore, if you have a patient for whom glasses have been ordered and no mydriatic has been used, you can safely assume that these are incorrect and that little or no benefit will result from their use.

In the second place, notwithstanding the use of the cycloplegic, the lenses may be incorrect. For example, the patient's static refraction is a plus .50 sphere combined with a plus .75 cylinder (axis as yet undetermined). Either a plus .62 sphere combined with a plus .62 cylinder, or a plus .37 sphere combined with a plus .87 cylinder, will, in these three cases, correct perfectly the principal meridian. Vision will be about equally good, yet only with the first, the exact correction, will comfort follow. This is assuming also that the cylinder has been correctly placed. If the proper axis be at 90°, five degrees either side of this will induce discomfort instead of bringing relief. Therefore, only mathematically correct refraction work can be depended upon to cure eyestrain and the conditions which result therefrom. If this be appreciated it will be seen how futile is all this painstaking work if the patient insists on placing these lenses before the eyes in some contrivance that will not hold them squarely and firmly in position. The little girl who said "A lie is an abomination unto the Lord, but an ever-present help in time of trouble," might have said the same about eyeglasses. There is occasionally a nose which will hold eyeglasses in position, but how often do you see a pair straight across the face and in perfect adjustment? Not once in a hundred times. It is the height of folly to spend valuable time to determine the correct axis for the cylinder and then have the whole work brought to naught by a tilted eyeglass. Astigmatics should wear spectacles, and these only in rigid frames. Furthermore, it should be clearly understood that it is a waste of time and money unless the patient is willing to wear these glasses all the time; simply to use them for close-work does no good. Think of all the possible sources of error with the refraction gone over without a cycloplegic and then the lenses put into eyeglass frames, and you will cease to wonder why the patients will come back with the complaint that they are even worse than before they put on glasses. The eye is a vital organ, not a machine, and is subject to changes incident to the condition of its possessor; therefore it should not be assumed that glasses once fitted are

fitted for all time. Often temporary relief is obtained, and then the symptoms return: this is an indication for another examination. More particularly is this true for the child whose refraction is subject to frequent changes. In children, once a year at least there should be a reexamination: in the adult, once in about two years is the rule. There are also brought about changes in the nutrition of the eye, in its tension, and in the muscle balance by wearing a first correction, and for this reason a neurasthenic or one suffering from a reflex neurosis should have, in the beginning, the refraction worked out at frequent intervals.

Assuming that the oculist has done his part well, that he has given the proper lenses in the proper frames, examined both, and seen that the optician has filled the prescription correctly, put them upon the wearer and adjusted them in position, then also is demanded the cooperation of the patient. He must, if good results are to be obtained, wear the glasses constantly, keep them clean, and exactly in adjustment. Any violation of these rules means failure to obtain relief.

In conclusion, let me epitomize the essentials of this paper:

The ocular conditions which give rise to eyestrain may be refractional, accommodative, or muscular. The result is loss of neuricity. The effects are remote and reflex, and may be expended upon any organ, group of organs, the nervous system as a whole, or its separate divisions.

It is the little refractional errors which give rise to the greatest trouble: poor vision and eyestrain are not concomitant conditions, but exactly the reverse.

It is imperative to have the eyes of all children, of school age, examined under atropine: not only may health and comfort be conserved, but their whole future may rest upon this simple thing.

Refractional errors of high degree should be corrected, not because of any reflex disturbances, but to save the eyes from disease and to give their possessor better vision.

The investigation of all obscure nervous phenomena should begin with the eyes; often it will be necessary to go no further. Typical sick headache is pathognomonic of eyestrain; if it is not cured, in 99 per cent. it is the fault of the refractionist.

Finally, you cannot cure the disease unless you apply the remedy. Nearly right glasses will surely aggravate the symptoms, and relief can be obtained only by mathematically correct lenses in mechanically perfect settings.

DISTURBANCES OF GASTRIC SECRETION:

A PRACTICAL STUDY.

By M. GROSS, M.D.,

NEW YORK.

Anatomicophysiological.—The longitudinal fibers of the muscle of the esophagus are continued in their course toward the stomach: there they diverge radially, a strong bundle traveling along the lesser curvature toward the pylorus. At the greater curvature they are least developed. A contractile shortening of the muscular bundle at the lesser curvature serves to approximate the two ostia of the stomach, simultaneously raising the region of the fundus. On the other hand, owing to the slight development of the musculature at the greater curvature, it is just this part which in the presence of an abnormal demand is distended most and foremost. The longitudinal fibers then converge toward the pylorus in the shape of a funnel, and distinctly engage that part of the stomach which is known as the ampulla pylori, finally merging with the duodenum.

The annular fibers of the gastric muscle, however, become denser in the cardiac region, forming the cardiac ring, encircle the body of the stomach in uniform convolutions, and are probably the greatest contributing factor in demarkating the ampullar portion against the rest of the stomach by assuming an increased thickness and forming a strong ring—the sphincter proper of the pylorus—at the orifice of the stomach.

Functionally the ampulla is the real motor area of the stomach, the fundus representing more or less the digestive chamber in which chiefly the secretion of hydrochloric acid takes place, while the secretion of pepsin and rennet seems to be more evenly distributed over the entire stomach.

The ampullar portion of the stomach plays a still more important rôle in the motor mechanism of the stomach. Direct stimulation on the part of the gastric contents and reflex stimulation on the part of the small intestines (Pawlow) cause the ampullar portion of the stomach to contract almost simultaneously with the sphincter pylori like a cap pulled over the contents of the stomach which is thrown against it, allowing, in the initial stage, the fluid part of the contents still to escape through the pyloric orifice, while the more solid part is thrown back into the gastric cavity to be mixed again with gastric juice. These regular peristaltic movements and the noises produced by the pyloric passage may in favorable cases be perceived.

Experiments.—First Experiment.—A patient suffering from achylia gastrica ingests on an empty stomach 250 c.c. of lukewarm water, syphoning taking place a quarter of an hour later. The result shows that after this short time most of the ingested fluid has found its way into the duodenum; after half an hour the stomach is nearly always empty.

Second Experiment.—The same patient ingests upon an empty stomach 250 c.c. of a 1-10 normal hydrochloric-acid solution (Jaworski). After half an hour, more than half of the ingested fluid is recovered; only after the lapse of an hour or more the stomach is found to be empty.

Control Experiment.—A hydrochloric solution of the same strength is administered to a patient with a healthy stomach. In this case a larger portion of the fluid is recovered than in the case of the patient suffering from achylia gastrica, the withdrawals being made after the same lapse of time.

Third Experiment.—Ewald test breakfast is ingested by the patient suffering from achylia gastrica: upon withdrawal one hour later only a small quantity of the ingesta is recovered, which is inspissated and only slightly changed in appearance.

These three experiments, which I have conducted repeatedly, chiefly for the purpose of elucidating the function of the pylorus, justify the following

Conclusions.—(1) In a quiescent state the pyloric ring admits of the passage of gastric contents, though only to a minimal extent. At the same time there seems to exist a state of abnormal pyloric relaxation, which, however, may not be described as paralysis.

(2) It appears that the very susceptibility of the pylorus serves to regulate its function.

(3) The sphincter of the pylorus is stimulated not only by way of reflex from the small intestine,

but also direct from the stomach, either chemically or mechanically.

The pathological changes being merely the expression of a change or exacerbation of the physiological process, it is possible to deduce pathological conditions from the normal functions.

In hypochlorhydria, and even more so in achylia, the factors which normally regulate the pyloric functions are absent, with the consequence that the patent sphincter admits of a more or less accelerated passage of the gastric contents. The fluid portion escapes into the duodenum in a very short time, while the more solid portion of the ingested food remains deposited in the stomach for a longer period in consequence of the stronger mechanical irritation. We have therefore not to deal with hypermotility, as has so far been erroneously assumed.

The functional disturbances of the pylorus have up to the present not received that amount of attention which this important chapter of gastric pathology merits. If we consider the indirect and direct consequences which even a short-lived disturbance of the normal mechanical function of the pylorus occasions, it must be admitted that a considerable portion of gastrological affections may be attributable to functional derangements. This is particularly pronounced in those cases of sphincteral disturbances caused by increased secretion of hydrochloric acid. Here we have to deal with the unpleasant consequence of continuous spasms of the sphincter pylori, which may be accompanied by more or less painful paroxysms.

Maxims.—1. Every case of hyperchlorhydria is really one of enhydrochlorhydria, *i. e.* the secretion of a fluid with a normal percentage of HC_1, which, however, is secreted in large quantities, forming, so to speak, an engorgement of hydrochloric acid. Again, hyperchlorhydria has frequently been identified with hypersecretion. Riegel already distinguished between these two affections in spite of Pawlow's experiments, or, perhaps, just on the strength of them. Bickel, too, seems to hold the same opinion. The difference is probably this, that in hypersecretion large quantities of HC_1 are very rapidly exuded, while in hyperchlorhydria there are probably large quantities of gastric juice which exude only gradually.

2. The pain need not necessarily be caused by an ulcus (Bourget)*; the mere presence of abnormally abundant secretion of normal concentration may occasion severe pain, owing to the irritation which the fluid exerts upon the pylorus.

3. As mentioned above, in nearly every case of hyperchlorhydria there occurs a secondary spasm of the pylorus of varying duration and pain. Its immediate consequence is the retention of the gastric contents, which occurrence may in the beginning be compensated by hypertrophy of the gastric musculature. This, however, is not always the case, especially in the initial presence of atonic muscles, interfering either completely or partly with such compensation.

4. Erosions and ulcers, often associated with hypersecretion, are a frequent cause of the severe paroxysms of pain which accompany the contractures of the pyloric ring, the pains increasing in intensity the nearer the anatomical lesions are situated to the pyloric ring (Bourget).

5. The majority of hyperchlorhydria cases are of neurotic origin.

6. Hypochlorhydria of a more or less permanent nature is much less frequent than hyperchlorhydria, while achylia is rarer still. Excluding the rare cases of hypochlorhydria of neurotic origin, deficiency of hydrochloric acid is often observed in organic affections of the gastric mucosa, in carcinoma, in anemic conditions and intoxications; in short, in conditions which are accompanied by faulty nutrition of the gastric parenchyma.

7. Hypersecretions are either (*a*) transitory, or (*b*) continuous.

The transitory cases are subdivided into (1) hypersecretio transit. digest. simplex; (2) hypersecretio transit. digest. prolongata; (3) hypersecretio transit. digest. periodica; the continuous cases into (1) hypersecretio continua simplex; (2) hypersecretio continua exacerbata.

8. Hydrochloric findings in general, whether disclosing absence, normal presence, or excess of HCl, present a symptom susceptible of many interpretations, as is evident from the above explanations, and which can only be diagnostically utilized in conjunction with a series of concomitant manifestations and the result of physical and other methods of examination.

Therapy.—Only a few words will be needed in regard to the treatment of hypochlorhydria and achylia, in so far as it is indicated to replace the deficient hydrochloric acid, without taking into special consideration the causes giving rise to these affections. Leo recently made interestnig and practically important investigations in regard to the effect and method of administration of HCl-pepsin solutions. He found that the exhibition of HCl in combination with pepsin enabled the affected gastric mucosa to respond to the ingested actual food with increased formation of HCl; further that the solution causes in the stomach already a distinct protolysis. This fact might be of importance in achylia, especially as the same solution also exerts an important influence upon the intestinal digestion of albumin. Add to this the stimulation of the pancreatic secretion and bile, and the favorable cures of diarrhea dependent on deficiency of hydrochloric acid seem susceptible of explanation. The HCl-pepsin solution is administered shortly before or during meals in order to obtain the best effect upon the gastric parenchyma.

The solution is composed as follows:

Acidi muriat. puri
Pepsini sicci, āā 10.0—5.0
Aquæ destillat. ad 50.0

Sig. One-half to one teaspoonful at every meal in a glass of sweetened tea, to be taken through a glass tube.

In order to relieve the derangement of rhythmical function of the pyloric ring which occurs in hypersecretion, remedies should in the first place be applied which, like the silver solutions and bismuth preparations, are supposed to have an astringent and antacid effect. The silver solutions in particular are also said to stimulate the mucous secretion according to recent investigations of J. Kauffman, and thereby form a protective layer against the attacks of excessive HCl secretion, or even of normal HCl secretion in the presence of a hypersensitive gastric mucosa. The process is likened to the recent successful administration of oil in ulcerative and kindred conditions, on the assumption that the oil, aside from its mechanical protective effect in the stomach itself, and neutralizing the HCl, may cause a reflex reduction of HCl by stimulating the pancreas. For the same purpose I have already in the nineties* used one-per cent. solutions of ferrum sesquichloride, and latterly Bourget has arrived at the same result.

*Die Krankheiten des Magens, by Louis Bourget.

**Therapeutische Monatshefte*, April, 1896.

Both the causal and symptomatic demands are best satisfied by intelligent application of the alkalies, their exhibition bringing about not only a reflex reduction of the HCl secretion from the small intestine, but also having a palliative effect upon the spastic pyloric occlusion by directly blunting the power of the hydrochloric acid. The alkalies will therefore have the most beneficent effect if taken half an hour before meals and two to four hours after, these being the periods at which the hydrochloric values usually and demonstrably attain their climax.

Bourget has shown that alkalies in one-per cent. solutions are capable of attaining the desired end, namely facilitating the rhythmical opening of the pylorus, as in these cases there is not so much a question of completely neutralizing the hydrochloric acid, as of lowering the power of the secretion by one or two degrees. Concentrated solutions of the alkalies are out of the question, constituting as they do an increased stimulus to the secretion of hydrochloric acid.

A subsequent increase of HCl may be counteracted by repeated administration of small doses of the same alkaline solution.

℞ Sodii bicarbon. 20.0
Sodii phosphor.
Sodii sulphur. āā 6.0
Extr. fl. Condurango 10.0
Aquæ 120

Directions—Add 2 quarts of water, take ½ to 1 glassful before meals and the same quantity 2 hours after light meals, or 4 hours after heavy or meat meals.

Should there be any complications indicating a renewed augmentation of hydrochloric values, I order tablespoon doses of the same solution, and more.

This method of treatment has not only been successful in rather chronic cases, but, in conjunction with one-per cent. solutions of the sesquichloride of iron, taken at bed time and on arising, has proved very efficacious in cases of recurrent ulcus.

In conclusion a few words concerning the diet in hyperchlorhydria. Permissible are: tea with cream, rich cocoa, toast, much sweet butter, eggs; all cereals boiled in water and inspissated, with hot milk, cream, or sweet butter poured over; meat which has been boiled a long time, the white sorts preferred; steamed vegetables with butter poured over; sweet fruit; farinaceous substances in the shape of puddings, provided they do not cause pyrosis.

315 Second Avenue.

DRAINAGE OF WOUNDS.*

By R. W. KNOX, M.D.,

HOUSTON, TEXAS.

The treatment of wounds constitute a considerable portion of our minor surgery and offers a field for discussion in which there has always been much difference of opinion. It might be stated at the very outset that wounds differ so greatly in their character and location that the treatment must necessarily vary with the exigencies of the case. While this is true to a limited extent, the underlying principle is the same in the majority of cases. It would be an insult to the intelligence of this audience to state that all wounds should be made and kept as surgically clean as possible, and that punctured and pocketed wounds should be laid open and drained and that pus should always be evacuated. These are self-evident truths, about which there is no difference of opinion, and yet we see wounds that fail to heal and wounds that cause infection, both local and general, in spite of the ordinary methods of handling. It is a well-known fact that the majority of wounds of any magnitude become infected at least locally. The infection may depend on the condition of the patient physically, as well as the character of the injury. We have all seen slight injuries result seriously, which we have attributed mainly to the peculiarly virulent action of the infecting agent. As a rule, however, the deeper the injury and more severe the laceration and attendant contusion, the greater the danger. The rupture of the smaller blood-vessels, with its resultant ecchymoses and effusion of serum together with destruction of tissue, furnishes an excellent culture medium for the development of germ life.

To realize the futility of freeing a wound entirely of its infection, we have only to consider the difficulty of completely sterilizing the normal hand where the conditions are much more favorable for cleansing and disinfection than in almost any character of wound. With this idea in view, viz., that wounds are rarely sterile, it has always seemed rational to me that a method should be adopted whereby drainage should be facilitated to the highest possible degree, and in this way prevent the inconvenience, if not danger, from an accumulation of septic products. Any method that may be effectual must depend largely for its virtue upon its early adoption. No better object lesson can be found than the occasional mistake of closing with sutures deeply contused wounds and noting the untoward results, as well as the immediate relief when the pent-up secretions are relieved. Gauze and drainage tubes are excellent agents when indicated on account of the nature of the wound, but by far the safest, best and most effectual and unvarying in its results as a means of getting perfect drainage is the use of moist heat. Heat and moisture kept constantly applied to a wound favor the elimination of its poisonous products much more rapidly than any other means at our disposal. It is the rule to use moist heat only on wounds already known to be infected, but it is just as rational to use this with the idea of preventing infection. Certainly there is no surer way of keeping a wound clean, and at the same time relieving pain. Also in my opinion a general infection from an injury would be among the surgical curiosities if this plan was always adopted; and this, no matter how severe the injury or how dirty the wound. I have had abundant opportunity to test this in cases of injury by revolving cogwheels or when a limb has been rolled over by a heavy object and dirt and grime has been ground into the deeper fascia and even the muscles themselves.

The temperature of the dressings in such cases must be kept evenly and continuously about 125° Fahrenheit. It should be borne in mind that the skin does not tolerate as high degree of moist as dry heat, and the nurse should be carefully instructed along these lines. The skin may be blistered by over-heated bags, and yet the patient be entirely comfortable. In the absence of a thermometer, the nurse should be instructed to use water of a temperature that her fingers can tolerate for ten seconds

*Read before the Bexar County Medical Society, March 12, 1908.

without serious discomfort. Certain parts, notably the hands and feet, stand a greater amount of heat than other parts of the body, and it is well to use a higher temperature in those cases, when a general infection has already begun. After this treatment is begun a marked drop in the temperature is noticed within the first twenty-four hours. No general infection occurs when treatment is begun early, although from the very character of the wound we would expect it under ordinary methods of handling. The older method of treatment was to cut well outside of the injury and leave no lacerated tissue for fear of general infection and its possible consequences. Valuable portions of the anatomy, notably the hands and feet, have no doubt been thus needlessly sacrificed. With the danger, however, of blood poisoning removed, we can afford to be far more conservative, and the laceration of a member does not necessarily mean its entire loss. We recognize the fact that the most cruel of all wounds are found among railroad injuries and where the most radical operation is often the most conservative, yet a severely injured member that might otherwise have been sacrificed may by proper treatment be saved and become useful. In order to accomplish the results expected much care must be exercised in the preparation of the dressing, such as sterilization, etc., as well as a proper application, including continuous heat and moisture kept up for a proper length of time. A moist dressing is of little service if left unchanged and allowed to become a dry dressing after a few hours. No harm is done to the healthy skin or tissue unless a careless nurse has allowed the dressings to become overheated. By this method all pain is relieved, the swelling is reduced, a beginning infection is abated, and granulation rapidly springs up. A general infection in wounds, if properly treated, is rare after the first few days, and healthy granulation is an invariable sign that the danger is past and the more active treatment can be discontinued. It is remarkable with what quickness a devitalized tissue is thrown off, leaving only material that the original injury had not destroyed. When there is no further need for the warm applications and a considerable extent of raw surface exists, the use of dressings saturated with boroglyceride is especially useful. It acts as a semimoist dressing in that it facilitates drainage, keeps the wound free from odor and pus, prevents sticking of the dressing to the raw surface, and does not interfere with cicatrization or the growth of skin grafts. No other dressing, with which I am acquainted, answers so many valuable indications and has so few objections at this stage of the treatment. For the retention of heat and moisture in the class of cases mentioned, thick heavy dressings should be employed. I am in the habit of using what may be called the blanket dressing of the size and shape of towels, either of cotton or flannel. These are wrung from hot water and in many cases instead of enveloping the limb are folded and laid beneath it and alongside and over the limb and supported by hot water bags, while beneath is placed an oil cloth or Kelly pad. In this way an almost continuous irrigation can be used if necessary and especially in those cases where the limb has sustained a compound injury and handling is painful. A solution of boric acid is best for irrigation and a teaspoonful of formalin to the quart of water is an excellent deodorizer. On the average case the dressings should be changed about twice in twenty-four hours.

In the case of minor injuries, such as pricks, punctures, slight lacerations, etc., bad results do not usually follow, but in my opinion it is much safer and nearly as convenient to apply moist heat, rather than any of the long list of healing salves, powders, or liniments. All of these act more or less as irritants and retard rather than promote healing. In fact anything that tends to retain secretions within the wound is at best an uncertain agent. Nature will do the healing in the best possible manner if not handicapped by a misdirected kindness on the part of the doctor.

The saddest cases with which we have had to deal, an opprobrium to the art surgical, are those which have started as an insignificant injury and afterwards involved important structures. A striking example of this is found in slight initial injuries to the fingers and hands, afterwards involving the tendon sheaths of the palmar surface and wrist with a resultant permanent partial disability. In gunshot injuries we have the same danger that could be avoided by proper drainage.

In conclusion my excuse for presenting this subject is the settled conviction that we are wide of the mark if we fail to appreciate the value of plain moist dressing, as a means not only of preventing, but of relieving infection. The rationale of this method of treating wounds, besides that of increased drainage, will not be considered from the fact that I have no well-defined ideas to to its pathological action. Our knowledge of the action of heat upon inflammation in general is at best only empyrical. Like many other good things the idea is not new, as witness the effect of the flaxseed poultice as used by our grandmothers from time immemorial. This form of poultice is somewhat uncleanly and liable to become infected in careless hands, but under the proper conditions it answers a most admirable purpose.

The length of time moist dressings should be applied depends on the nature and gravity of the wound as well as the early or late defervescence of symptoms. In extensive or deep lacerations, the most important consideration is an early application to prevent an infection spreading beyond the original limits of the wound. The success of this treatment will depend upon the careful and efficient manner in which it is carried out. Next to the moist dressing itself in importance is a clean, able, and conscientious nurse. A surgeon who is fortified with these two important aids, need not fear the disastrous results that follow unclean wounds.

I would not be misunderstood as advocating this form of dressing for all cases. When a wound is slight and known from its very nature and handling to be aseptic, a dry dressing is indicated. When in doubt, wet dressings are best and may save some future anxiety. If we can free ourselves from the old idea that heat and moisture favor suppuration, we will have made long strides toward the proper treatment of wounds.

Immigration Statistics.—During the month of March immigration into this country decreased 76 per cent., as compared with the same period in 1906, and 77 per cent., as compared with 1907. The total number of immigrants entering the country was 32,517, whereas for March a year ago it was nearly 140.000. The greatest decrease was in the number of Italians coming to this country.

SOME OBSERVATIONS ON THE OPHTHALMO-TUBERCULIN REACTION.

By THEODORE B. SACHS, M.D.,

CHICAGO.

Since the announcement by Birch-Hirschfeld and later by Calmette of their observations on the reaction produced in the conjunctivæ of tuberculous subjects by the instillation of a solution of old tuberculin (this being proposed as a new diagnostic test of tuberculosis), investigation along these lines has been carried on by numerous observers all over the world. In most cases, as suggested by Calmette, a 1 per cent. solution of precipitated tuberculin was employed for instillation into the conjunctival sac, and the result recorded as reaction—negative, mild, moderately severe, or severe.

Experience so far accumulated points to the occurrence of an inflammatory conjunctival reaction in a vast majority of patients positively tuberculous, also in a large number of cases of suspected tuberculosis, and in a small fraction of those pronounced positively nontuberculous. The test is still *sub judice,* and its ultimate value as an accessory diagnostic method in suspected tuberculous cases can be determined only by further investigation, which no doubt will be energetically carried on, in view of the vast importance of any new method that may throw some light upon the obscure phenomena of a disease so common and still so frequently obscure in its early manifestations.

The solution of numerous problems in connection with the ophthalmo-tuberculin reaction of Calmette is absolutely essential before a true estimate of its value can be established; most important of these is the nature of the conditions favoring or preventing its occurrence.

In applying this test to various groups of cases at the Edward Sanatorium of the Chicago Tuberculosis Institute, in the tuberculosis clinic, and in my private practice, the following results were obtained.*

1. Cases of pulmonary tuberculosis (with tubercle bacilli in the sputum), 22 cases. Mild reaction (+), 8; moderately severe (++), 8; severe (+++), 2; negative (—), 4. Seven cases, in which a mild reaction occurred, were classed under the heading of moderately advanced pulmonary tuberculosis of the chronic type; one case was in the same stage but was running an acute course. Of the 8 cases, with moderately severe reaction, four were incipient (in good general condition); four — moderately advanced cases of the chronic type. The two cases giving a severe reaction were moderately advanced but in fairly good general condition. Of the four with negative reaction, all were in the far advanced stage (considerable emaciation, pronounced anemia, etc.).

II. Cases of pulmonary tuberculosis (no tubercle bacilli in the sputum), 39. Reaction negative, 11; doubtful, 1; mild, 5; moderately severe, 22.

The eleven cases with negative reaction were all in the incipient stages of pulmonary tuberculosis. Three of these were just recovering from a moderately profuse hemorrhage; three were considered cured cases of pulmonary tuberculosis (under observation for two years previous to the instillation of tuberculin); one was a twelve-year-old girl with Pott's disease and indefinite findings in the lungs, and one—a boy twelve years old in the incipient stage of pulmonary tuberculosis. The one doubtful reaction was in a patient in the incipient stage. Four of the five cases giving a mild reaction were in the incipient stage; one an arrested case of moderately advanced disease. Of the twenty-two cases with moderately severe reaction, eighteen were in the incipient stage, two moderately advanced (arrested), one incipient (arrested), one a case of tuberculosis of the cervical glands in a boy fifteen years of age (pulmonary findings slight). Of the sixty-one tuberculous cases, in which the test was used, twelve were between eleven and twenty years of age, forty-nine between twenty and forty years.

III. Cases of suspected tuberculosis (suspicion based on some suggestive symptom, such as slight hemoptysis, etc., without any additional corroborative symptoms or signs). 11. Reaction negative, 9; mild, 2.

IV. Physicians and nurses in frequent association with tuberculous patients, 6. Reaction negative in all.

V. Various diseases (tuberculosis excluded by study of clinical history and findings on physical examination), 22 cases. Reaction doubtful, 3; mild, 1; negative, 18. Doubtful reaction occurred in one case of chronic valvular disease, one of chronic parenchymatous nephritis, and one of acute bronchitis. One case of chronic bronchitis and emphysema gave a mild reaction. Negative reactions occurred in three cases of chronic gastritis; two cases of chronic interstitial nephritis; three of neurasthenia; two of chronic rheumatism; three of mitral insufficiency; one each of pleurisy following contusion of the chest, Basedow's disease, syphilis, cirrhosis of the liver and diabetes.

VI. Normal individuals, 10. Reaction negative in all. In recording various groups of cases in which conjunctival instillation of tuberculin is practised it may be desirable to classify them according to stage, activity of the process, age of the patient, extent of association with tuberculous patients, etc. I have deemed it proper at this stage to record only my observations, refraining from any generalizations. In sixty-one cases, positively tuberculous, the reaction was negative in about 20 per cent. of this number (some of the latter in the advanced stages of the disease). In thirty-eight individuals, pronounced free from tuberculous disease, a positive reaction occurred only once. No harmful after effects of the tuberculin instillation were present in any of the cases, even with severe reaction.

My thanks are due to my associate, Dr. M. Biesenthal, for his assistance in the observation of cases.

100 State Street.

*One drop of a 1 per cent. aqueous solution of precipitated old tuberculin (as used by Calmette) was employed in all cases. The results were classified according to the schema proposed by Dr. Edward R. Baldwin, Saranac Lake, N. Y. (similar to one recently given also by Professor Comby): Negative, no difference in color when lower eyelids are pulled down and compared; doubtful, slight difference with redness of caruncle; + = distinct palpebral redness with secretion; ++ = ocular and palpebral redness with secretion well marked; +++ = deep injection of entire conjunctiva with edema of lids, photophobia and secretion.

Suicide Statistics.—According to statistics recently published by the Swiss Government, there have committed suicide during the last thirty-five years 16,640 persons in Switzerland, 323,600 persons in Germany and 274,000 persons in France. German official figures put the number of suicides in Europe yearly at 70,000. Cases in the German Empire itself have risen from 10,510 in 1895 to 12,730 in 1905. In America the number is estimated at about 3,000 annually, and is increasing.

MEDICAL RECORD.

A Weekly Journal of Medicine and Surgery.

New York, May 30, 1908.

THE SPASMOPHILIC DIATHESIS.

THAT the older conception of the important rôle played by diathesis in the etiology of disease has not entirely died out is evidenced by the important contributions recently made by Duckworth and others to the literature of this subject. That diathetic conditions have been weighty factors in the evolution of diseases peculiar to childhood, has been exemplified by the almost obsolete "scrofulosis" of early medical terminology, a term which has recently been transmuted at the hands of Czerny into the more elegant and scientific expression, "the exudative diathesis." In addition to this there has lately appealed to the German pediatrists particularly the necessity of coining a new expression, the "spasmophilic diathesis," comprising a group of cases of fundamental importance and widespread existence during the early years of life. This term was first applied by Thiemisch (*Medizinische Klinik*, No. 17, 1906) to the large group of cases occurring during childhood, in which there is an abnormal mechanical and electrical excitability of the peripheral motor nerves, presenting itself under three different clinical aspects, namely, tetany, laryngeal spasm, and general convulsions. The characteristics of this diathesis are its hereditary nature, its association with artificial feeding, and its highest incidence during winter and spring, and during the latter half of the first and the first half of the second year of life. The keynote to the prophylaxis and therapy of this condition is the use of breast-feeding.

In support of the theory advanced that the spasmophilic diathesis is a form of latent tetany are the results of the physiological investigations made by F. Pineles (*Jahrbuch für Kinderheilkunde*, Vol. 66, No. 6) on the pathogenesis of infantile tetany. This observer found that infantile tetany is identical with the postoperative tetany of adults, the cardinal symptoms in both being a mechanical and galvanic hyperexcitability of the peripheral motor nerves, as revealed in Trousseau's, Erb's, and Chvostek's symptoms; at the same time there is a peculiar reversal of the law of response to electrical stimulation, the cathode opening contraction occurring with currents less than five milliampères, and the anode opening contraction exceeding the anode closing contraction. Besides, common to both conditions, are the peculiar tonic contraction of the fingers, the epileptiform attacks, and the trophic disturbances.

At the meeting of the German Pediatric Society, held in Dresden in September, 1907, Professor Escherich referred to the fact that galvanic hyperexcitability is a widespread phenomenon during childhood, recurring even in apparently healthy infants. Thus, of 329 infants in the Vienna hospital, the percentage showing this condition varied from 2 in the first month of life to 52.6 in the sixth month, the majority of instances being furnished by artificially-fed and rachitic children. Escherich noted that within the past decade the conception of tetany has broadened into that of one of the most comprehensive of the disorders of early life, including the cases of laryngeal spasm and eclampsia, occurring in early infancy, no less than the chronic cases of so-called tetany of later childhood. The excessive excitability of the nervous system to galvanic stimulation is a diagnostic point of cardinal importance in all these conditions. There are to be differentiated two groups of cases, the tetanoid condition, and tetany proper. In the former there are mechanical and electrical excitability, with various convulsive manifestations, while the latter group is characterized by the presence of muscular twitchings, localized spasms, spasmus glottidis, and general convulsions, in addition to the electrical and mechanical phenomena. Tetany is further classified into tetania infantum, occurring up to the third year of life, and tetania puerorum, occurring after this age. The occurrence of tetany as a sequel of extirpation of the thyroid gland laid the foundation for the discovery of the actual pathogenesis of this condition.

It is not, however, in anomalies or absence of the thyroid gland that the cause of tetany or the tetanoid condition is to be found. With the abundant material provided by the Vienna pediatric clinic at his disposal, J. Yanase studied the structure of the parathyroids in cases of increased galvanic irritability in children (Proceedings of the German Pediatric Society, September 16, 1907), and discovered the following pathological processes: Amyloid degeneration, miliary tuberculosis, round-celled infiltrations, microbic emboli, and, most frequently, hemorrhages into the glandular substance. In eighty-nine cases hemorrhages were found thirty-three times, that is, in 37 per cent. of the cases. The first traces of the parathyroid hemorrhages were discernible during the first two weeks of life, and were attributed to intrauterine asphyxia. Later, and continuing until the end of the first year, these bleedings became encapsulated, the blood pigment was taken up by leucocytes and deposited in the connective tissue. From this time on, until the fifth year of life, the only evidence remaining was the presence of this pigment, which afterward disappeared entirely. It is explained that the hemorrhages damage the antitoxic functions of the parathyroids, and thereby induce the disposition to the tetanoid condition.

THE AGE OF EFFECTIVE WORK.

IT will be remembered that Professor Osler said a few years ago, in the speech which has made him famous, that the "effective, moving, vitalizing work of the world is done between the ages of twenty-five and forty," and that we might subtract from

the sum of human achievement all that has been done by men over forty without missing anything of practical value to the world. Other things he said jokingly in disparagement of the world's workers on the shady side of forty, but that he was in earnest in making the statement above quoted he has never denied so far as we know. This astounding statement, coming from one of Osler's culture and wide reading, challenged attention and set men to thinking of the great achievements of middle-aged men and even those far advanced in years, and numerous examples of this kind were collected. Nevertheless, the lists of old workers were comparatively short, and an uncomfortable feeling remained that perhaps the old boys were after all of little use in the world, mere veterans lagging superfluous on the stage. Any such doubts may now be set at rest by reading the really wonderful record of achievement by men, some long past middle life, and all crossed the "dead-line" of forty, which Dr. W. A. Newman Dorland presents in the April and May issues of *The Century*.

Leaving out of the reckoning the artists—poets, musicians, painters, sculptors, romancers, essayists, historians—whose work has brought joy into the world, we are reminded by Dr. Dorland's record that not a little of the practical work, "the effective, moving, vitalizing work of the world," has been accomplished by men over forty. Among the things that would be missed were we to subtract the work of the older men would be printing from type, the discovery of dynamic electricity, of oxygen, of vaccination, of the circulation of the blood; the invention of the reflecting telescope, of the Bessemer process of making steel, of the double-acting steam engine, of railways, and all the inventions and discoveries, and the advances in chemistry, medicine, manufactures, and commerce which have naturally followed these epoch-making achievements. History would have to be rewritten, for the names of Washington, Lincoln, Grant, Sherman, Kossuth, Talleyrand, Peel, Cavour, Nelson, Cromwell, Richelieu, Luther, John Knox, Palmerston, Bismarck, von Moltke, Garibaldi, Columbus, and a host of others would have been forgotten in the absence of their most notable deeds. In science, in manufacture, in commerce, in diplomacy, in literature, in painting, in music the gaps would be many and great, and the world would be centuries behind where it is today could the results of the work of men who had passed Osler's limit of forty years be eliminated.

Approaching the question from another point, Dr. Dorland has computed the average age of the great benefactors of the race at which each performed his masterwork, and finds that for the workers the average age is forty-seven, and for the thinkers fifty-two. The corollary of this is evident; it is, the writer says, that "provided health and optimism remain, the man of fifty can command success as readily as the man of thirty." The facts which Dr. Dorland brings forward as result of this painstaking research prove beyond question the absurdity of Osler's assumption, and should give heart to those who may have been influenced more or less unconsciously by his gloomy address to regard themselves as out of the race and past the age of usefulness to the world and their fellows.

ANATOMICAL CHANGES IN THE ADRENALS IN ARTERIOSCLEROSIS.

Four years ago Josué produced atheroma in the aorta of rabbits artificially, by intravenous injections of adrenalin. He believed it was similar in structure to atheroma found in the human aorta and therefore concluded that the latter was probably due to a change in the adrenals. This change he claimed consisted of a hyperplasia which caused an increased secretion, the excess getting into the general circulation and causing arteriosclerosis. Since that time many observers have shown that the artificially produced and the human arteriosclerosis are quite different histologically, the most marked changes of the former being in the media while those of the latter are found in the intima. While this fact has been repeatedly pointed out no one has hitherto made any attempt to verify or contradict Josué's other claim that an increased secretion of the adrenals caused the arteriosclerosis.

Recently, however, in an interesting article in the *Zeitschrift für klinische Medizin*, Volume 64, Nos. 3 and 4, H. Landau has reported in detail his histological findings in the adrenals of sixteen persons who during life had presented various degrees of arteriosclerosis, the majority of them intense degrees, either local or general. He also examined the glands of four patients who died of tuberculosis and of two who died of pulmonary emphysema. His pathological findings included a thickened capsule with numerous large bundles of smooth muscle fibers in it, also hyperemia, and small-celled infiltration. When there was peripheral arteriosclerosis similar changes were found in the vessels of the gland, with occasional smooth muscle bundles between them. There was usually an increase of connective tissue and atrophy of parenchyma cells, this at times having gone on to a cirrhosis; the latter condition when present was accompanied by an increase of pigment cells. In a few cases there was present a diffuse hyperplasia of the gland tissue. In two cases amyloid degeneration was found.

We can readily see that all these changes are of an atrophic and inflammatory nature and are no different from the changes found in other organs in cases of arteriosclerosis. It might be said by some that increase of pigment cells and diffuse hypertrophy point to an increased function of the adrenals. This view can hardly be taken, however, when we consider that these changes were present only in a few cases and that they might be explained on the ground that increased pigment is often found in the presence of atrophic changes and that hypertrophy of one part of an organ frequently accompanies atrophy of other parts of the same organ.

Landau's pathological findings therefore do not substantiate the presumption of Josué as regards the part which the adrenal plays in the etiology of arteriosclerosis. In no case did Landau find any changes in the individual cells or in the general structures of the gland which could in any way lead one to believe that a definite causal relationship existed between it and arteriosclerosis.

The Hydrostatic Lung Test.

Whether or not an infant was stillborn is frequently a question of great importance. Even though it may have had a brief extrauterine existence without breathing, the best evidence that it has lived is that it has breathed. To prove the latter the lung test may be said to head the list; it includes the estimation of the height of the diaphragm, the amount of space the lungs occupy in the thoracic cavity, whether they cover the thymus and heart, their color, and whether they float in water or not. The hydrostatic test as a proof of life was first used in court in 1683; before long, however, objections were raised against its real value. It has been demonstrated time and again that any of the methods of artificial respiration, intrauterine breathing of air (vagitus uterinus), and gases caused by putrefaction, can bring air into the lungs and cause them to float, yet the child may never have breathed outside of the uterus. In the *Zeitschrift für Geburtshülfe und Gynäkologie* (Vol. 61, No. 3) F. Ahlfeld has shown that lungs can float even though they contain no air. Such lungs he found contained vernix or meconium, both lighter than water. On the other hand, it has been found that lungs of infants who lived from five to eighteen days did not float, and that other lungs which sank contained air in places when incised under water. We thus see that the fact of the child having lived cannot be excluded when the lungs sink, and that floating lungs point to the child's positively having lived only when artificial respiration, putrefaction, vagitus uterinus, and the other factors above mentioned can be excluded, and when the other positive lung signs are present. The hydrostatic test is the best of those which we possess to prove life has existed, but it is by no means as infallible and valuable as it is generally believed to be.

Histological Evidence of Acidosis.

The theory that the striking clinical picture of acute gastroenteric intoxication of infants is in many cases due to the condition of acidosis has gained much ground within recent years. The excess of ammonia and of acetone in the urine of such patients, the profound prostration and apathy, the frequent fatal outcome, all show a striking analogy to the type of such disturbance of metabolism, the acidosis coma of diabetes. Tugendreich, writing in the *Berliner klinische Wochenschrift* of May 4, 1908, furnishes some very direct evidence in favor of this theory. By the use of microchemical methods, he has succeeded in obtaining the same chemical reactions in the tissues of patients dying of apparent acidosis in the course of gastroenteric disease as have previously been demonstrated in experimental acidosis of dogs and other animals. The plasma of the liver cells, that normally stains with eosin and other acid dyes, became basophile in its staining relations, thus showing that the clinical picture observed was accompanied with the excess of acid in the tissues. Other tissues did not show such characteristic reaction, this being quite in line with the modern tendency to look upon the liver as the chief organ of normal and pathological metabolism in the body. Microchemical reactions have not received as much attention as other methods of pathological diagnosis, although a study of them promises rich rewards. Tugendreich's successful work ought to stimulate the interest in this branch of modern laboratory technique.

Renal Diabetes.

The existence of a purely renal type of diabetes, that is, the excretion of sugar in the urine caused by functional or organic inefficiency of the kidneys, has been doubted by such an authority in the diseases of metabolism as von Noorden. Bönninger thinks (*Deutsche medizinische Wochenschrift*, April 30, 1908) that the proof of such a condition must consist in the existence of glycosuria without an accompanying hyperglycemia, in the impossibility to control the sugar excretion by dietetic changes, and in such a long duration of the disease as to exclude the alimentary glycosuria of a person with diminished tolerance to sugar or some obscure temporary derangement of metabolism. He communicates the particulars in the case of an alcoholic patient under his observation, which seem fully to meet the above requirements. The sugar content of the blood was continuously low, the glycosuria could not be affected one way or the other by any changes in the diet, and the symptoms had persisted for a number of years. He rightly concludes that only further observation of this and similar cases can clear up the relation between the condition observed in his patient and the common type of diabetes accompanied with the excess of sugar in the blood and affected by dietetic measures. Meanwhile, the temporary existence, at least, of a purely renal type of diabetes seems to be established by his observation.

News of the Week.

The Tuberculosis Bill.—Governor Hughes has signed Senator Cassidy's bill which declares tuberculosis to be an infectious and communicable disease dangerous to the public health, and provides for the reporting of all cases to the local health authorities. It also provides for the free examination of sputum by the health authorities in all suspected cases; for the protection of the registration records from public inspection, and for the disinfection or renovation of the premises after death or removal of a person having tuberculosis. The occupancy of premises vacated by a person having tuberculosis is prohibited until the directions of the Health Department providing for disinfection or renovation have been complied with. The attending physician is required to report to the health officer, on blanks to be furnished for this purpose, a complete statement of the procedure and precautions taken by him in a case of tuberculosis coming to his notice, and the physician shall receive for such report a fee of $1. Failure on the part of the attending physician to comply with the provisions of this act will make him liable to a fine not to exceed $100 or six months in prison or both. Violation by any one of any section of the act is declared a misdemeanor punishable by a fine of not less than $5 or more than $50.

The Harvey Society.—At the annual meeting of the Harvey Society, held May 15, 1908, the following officers were elected for the coming year: *President*, James Ewing; *Vice-President*, Simon Flexner; *Treasurer*, Edward K. Dunham; *Secretary*, F. C. Wood; *Council*, Graham Lusk, S. J. Meltzer, Adolph Meyer. The society adopted the following resolution: "In the desire of Dr. Graham Lusk not to undertake again the duties of president of the Harvey Society, its members express to him their cordial appreciation of the great value of his services to the medical sciences in this country in founding the society, in successfully administering

its affairs during its early growth, and in placing it upon a substantial basis. The place now occupied by it abundantly demonstrates the wisdom of Dr. Lusk in organizing a medium of communication between the laboratory and the medical practitioners; and whatever the society shall accomplish in the future will be due in no small part to the worthy example which he has set."

Dr. S. A. Knopf of this city has been elected Professor of Phthisiotherapy to fill the newly-created chair at the New York Postgraduate Medical School and Hospital.

Dr. Charles A. Groff has been appointed provisionally chief medical inspector of the Philadelphia Board of Health in the place of Dr. A. A. Cairns, resigned. Dr. Groff has been assistant medical inspector since 1901.

Dr. Charles T. King has been appointed assis-sistant resident physician in the Philadelphia Municipal Hospital to fill a vacancy caused by promotions.

Dr. James McFadden Gaston of Atlanta has been appointed by the foreign mission board of the Southern Baptist Convention to take charge of a new hospital to be erected at Lai Chou Fu, in the province of Shang Tung, China. The hospital over which Dr. Gaston will have supervision will be known as the Mayfield-Tyzzer Hospital, having been named for Drs. Mayfield and Tyzzer, of St. Louis, who are supplying the funds for its erection. Work upon it will not begin until Dr. Gaston arrives in China some time in September, and it is hoped to have it completed by the first of next year.

Mechanico-Therapy at the Vanderbilt Clinic.—As a memorial to her late husband, Samuel Matshak, his widow has given the money necessary to equip a department for surgical mechanico-therapeutics at the Vanderbilt clinic of the College of Physicians and Surgeons of New York City.

The Harlem Eye, Ear, and Throat Infirmary.—Ground was broken for the erection of the new building of this institution on Thursday, May 14. The institution is twenty-seven years old and has six thousand new patients annually. Dr. C. B. Meding is the surgeon and secretary of the Board of Managers.

Retirement of a Hospital Staff.—As the result of a reorganization of the Bushwick Hospital, Brooklyn, decided upon by the board of directors, the resignation of all the doctors connected with the visiting staff has been asked for. The letters asking for the resignations explained that the scheme for reorganization included the erection of a new building and an addition to the staff.

An Epidemic of Lyssophobia prevails in New York and vicinity as a result of the publication in the daily press, with needless details and scare heads, of a fatal case of hydrophobia. A war of extermination has been declared against the thousands of homeless dogs in the city, and if this is effectively carried out the resultant good may compensate in a measure for the distress caused by the sensational accounts in the minds of many timid persons who have been scratched or bitten by dogs.

The International Congress on Tuberculosis.—President Roosevelt has accepted the presidency of this Congress. Dr. Edward L. Trudeau has been elected honorary president, and Vice-President Fairbanks, Speaker Cannon, and the governors of the States have been asked to serve as vice-presidents. President Roosevelt's letter to Dr. Lawrence F. Flick, chairman of the Committee on Arrangements, is dated at the White House, May 12, 1908, and is as follows: "It is with great pleasure that I accept the presidency of the International Congress on Tuberculosis, which is to meet in this city on September 21, 1908, and extend its session to October 12, 1908. Official duties, however, may prevent my presiding at the initial meeting of the congress, in which case I will deputize Secretary Cortelyon. The importance of the crusade against tuberculosis, in the interest of which this congress convenes, cannot be overestimated when it is realized that tuberculosis costs our country two hundred thousand lives a year, and the entire world a million lives a year, besides constituting a most serious handicap to material progress, prosperity, and happiness, and being an enormous expense to society, most often in those walks of life where the burden is least bearable. Science has demonstrated that this disease can be stamped out, but the rapidity and completeness with which this can be accomplished depend upon the promptness with which the new doctrines about tuberculosis can be inculcated into the minds of the people and engrafted upon our customs, habits, and laws. The presence in our midst of representatives of world-wide workers in this magnificent cause gives an unusual opportunity for accelerating the educational part of the program. The modern crusade against tuberculosis brings hope and bright prospects of recovery to hundreds and thousands of victims of the disease, who under old teachings were abandoned to despair. The work of this congress will bring the results of the latest studies and investigations before the profession at large and place in the hands of our physicians all the newest and most approved methods of treating the disease—a knowledge which will add many years of valuable life to our people and will thereby increase our public wealth and happiness. The International Congress on Tuberculosis is in the interest of universal peace. By joining in such a warfare against a common foe the peoples of the world are brought closer together and made to better realize the brotherhood of man; for a united interest against a common foe fosters universal friendship. Our country which is honored this year as the host of other nations in this great gathering of leaders and experts and as the custodian of the magnificent exhibit which will be set up by the entire world, should manifest its appreciation by giving the congress a setting worthy of the cause, of our guests, and of ourselves. We should endeavor to make it the greatest and the most fruitful congress which has yet been held, and I assure you of my interest and services to that end."

Examination for Medical Interne, Government Hospital for the Insane.—The United States Civil Service Commission announces an examination on June 17, 1908, to secure eligibles from which to make certification to fill two, and possibly three, vacancies in the position of medical interne (male) and one vacancy in the position of medical interne (female), at $600 per annum each, with maintenance, in the Government Hospital for the Insane, Washington, D. C., and vacancies requiring similar qualifications as they may occur. Applicants must be unmarried, twenty years old or over, and graduates of not more than eighteen months' standing of a reputable medical college. Applicants should apply to the United States Civil Service Commission, Washington, D. C.

Rebel Against the Wearing of Uniforms.—Recently the Health Department inspectors of Chi-

cago appeared before the Council Health Committee to urge that their brass buttons and blue suits be discarded. The objections raised are that the coats are too heavy for summer wear; the inspectors are often mistaken for policemen; the brass buttons tarnish the fingers, and it is unbecoming the dignity of a physician to be uniformed. The whole matter was referred to a subcommittee.

The American Association of Medical Milk Commissions will hold its second annual meeting at the Chicago Beach Hotel, Chicago, Ill., on Monday, June 1, 1908, under the presidency of Henry L. Coit, M.D. This association is composed of one hundred and fifty physicians from various parts of the United States, who are engaged in milk commission work, and about thirty professional sanitarians and hygienists, who are connected with various phases of the pure milk movement. At the meeting there will be a discussion on the various phases of milk commission activity, including organization, scope of work, working methods, and new requirements for the production of "Certified Milk." Several papers or addresses will follow by physicians and hygienists who are prominently identified with this work in various parts of the United States. The secretary of the association is Dr. Otto P. Geier, 124 Garfield Place, Cincinnati, Ohio.

The National Medical Association.—The tenth annual meeting of this society of Negro physicians, dentists, and pharmacists will be held in this city on August 25, 26, and 27, 1908, under the presidency of Dr. P. A. Johnson of New York. The annual attendance at the three previous meetings, in Richmond, Philadelphia, and Baltimore respectively, has averaged about three hundred, but it is anticipated that there will be five hundred at least at the forthcoming meeting. It is gratifying to learn that all of the most prominent of the colored members of the profession are identified with this organization, for the good which can be accomplished by such a body is unquestionable. The salvation of the negroes in this country from the terrible havoc made in their ranks by disease must in the end be accomplished by physicians of their own race, and organization will be a powerful weapon to aid them in this struggle.

Alpha Omega Alpha Medical Scholarship Society.—The first international assembly of this society will take place in Chicago during the annual session of the American Medical Association. Dinner will be served at the Great Northern Hotel at 6:30 P.M., Wednesday, June 3. An address of welcome will be delivered by the Dean of Rush Medical College, and responses will be made by Drs. Barker, Burton-Opitz, Cannon, Dodson, Waite, Wesbrook, and Vaughan. Delegates from each of the fourteen chapters will have a place on the program. The secretary of the society is Dr. William W. Root, of Parker, Ind.

Franklin District (Mass.) Medical Society.—The annual meeting of this society was held at Greenfield, May 13. The officers elected were the following: *President*, Dr. J. W. Cram of Colrain; *Vice-President*, Dr. C. L. Upton of Shelburne Falls; *Secretary and Treasurer*, Dr. Clara M. Greenough of Greenfield; *Censors*, Dr. N. P. Wood of Northfield (supervisor), Dr. C. G. Trow of Sunderland, Dr. G. R. Fessenden of Ashfield, Dr. E. G. Best of Greenfield, Dr. G. A. Cooke of Montague; *Councilors*, Dr. H. G. Stetson and Dr. G. P. Twitchell of Greenfield; *Nominating Councilor*, Dr. G. P. Twitchell; *Commissioner of Trials*, Dr. F. E. Johnson of Erving.

Essex (Mass.) North District Medical Society.—At the annual meeting of this society, held May 6 at Lawrence, the following officers were elected: *President*, Dr. C. E. Durant of Haverhill; *Vice-President*, Dr. W. W. Pillsbury of Newburyport; *Secretary and Treasurer*, Dr. J. Forrest Burnham.

Polk County (Ark.) Medical Society.—At the annual meeting of this society, held at Mena on May 1, the following officers were elected: *President*, Dr. W. P. Parks; *Vice-President*, Dr. J. R. Davis; *Secretary and Treasurer*, Dr. F. A. Lee; *Delegate to the Arkansas State Medical Society*, Dr. J. R. Davis.

The Connecticut Valley Medical Association.—At the annual meeting of this association held at Bellows Falls on May 5, the following officers were elected: *President*, Dr. J. A. Stevenson of Chester; *Vice-President*, Dr. J. Corliss of Walpole, N. H.; *Secretary*, Dr. J. S. Hill of Bellows Falls; *Treasurer*, Dr. E. R. Campbell of Bellows Falls.

The Franklin County (Vt.) Medical Society met in annual session at St. Albans on May 13. The election of officers resulted as follows: *President*, Dr. A. L. Cross of Swanton; *Vice-President*, Dr. Alan Davidson of St. Albans; *Secretary* and *Treasurer*, Dr. E. A. Hyatt of St. Albans; *Delegates to the State Society*, Dr. G. C. Berkley of St. Albans, Dr. J. R. Patten of Fairfield, Dr. F. S. Hutchinson of Enosburg Falls, and Dr. E. M. Brown of Sheldon.

Brainard District (Ill.) Medical Society.—The thirty-second annual meeting of this society was held April 30, at which the following officers were elected for the ensuing year: *President*, Dr. John M. Wilcox of Clinton; *Vice-Presidents*, Drs. D. W. Deal of Springfield, John W. Bozarth of Mount Pulaski, and Chauncey W. Cargill of Mason City; *Secretary*, Dr. Harry S. Oyler of Lincoln; *Treasurer*, Dr. Chas. C. Reed of Lincoln; *Censors*, Drs. Irving Newcomer of Petersburg, Burton W. Hole of Springfield, and Chas. M. Noble of Bloomington.

Officers of Illinois State Medical Society.—At the fifty-eighth annual meeting of this society, held at Bloomington, May 19, 20, and 21, 1908, the following officers were elected for the ensuing year: *President*, Dr. J. W. Pettit of Ottawa; *First Vice-President*, Dr. J. L. Wiggins of East St. Louis; *Second Vice-President*, Dr. E. M. Eckhard of Peoria; *Secretary*, Dr. E. W. Weis of Ottawa; *Treasurer*, Dr. Everett J. Brown of Decatur. Quincy was selected as the place for holding the next annual meeting.

Obituary Notes.—Dr. Hiram Jennings Rowell died of pneumonia at Belen, N. M., on May 7. He was born in Missouri in 1879 and was graduated from the University Medical College, Kansas City, in 1900. He began practice in Excelsior Springs, Mo., but five years ago was obliged to go to the southwest on account of failing health.

Dr. A. E. Field of Barre, Vt., died on May 9 at the age of eighty-eight years. He was born in Berlin, Vt., and was graduated from Dartmouth in 1846. He practised for many years in Orange and Washington counties, and had resided in Barre since 1871.

Dr. Albert Bassett Smith died May 7 in Norwalk, Cal. He was born in Ohio in 1835, and was graduated from the Medical College of Ohio in 1856. He practised for many years in Iowa, in Des Moines since 1884, but removed to California about two years ago.

Dr. Daniel J. O'Sullivan of Lawrence, Mass., died May 8 at the age of fifty years. He was born in Lowell, and was graduated from the Bellevue

Hospital Medical School, New York City, about thirty years ago.

Dr. Albert Hunter Voorhies of San Francisco died on May 5 at the age of seventy years. He was born in Tennessee, and was a graduate of the Medical Department of the University of Pennsylvania in the class of 1860. He served in the medical corps of the Confederate army during the Civil War, and afterward practised in Memphis. He removed to San Francisco in 1881.

Dr. Stanley Gatch died in Tucson, Ariz., on May 1, at the age of twenty-five years. He was a graduate of the University of Kansas School of Medicine in 1905.

Dr. David Coulter Gamble of St. Louis died suddenly May 4. He was born in St. Louis in 1844, and was a graduate of the St. Louis Medical College in 1869. He was for a number of years clinical professor of otology in the Medical Department of Washington University.

Dr. Thomas Francis Stanton of Bridgeport, Conn., died May 8 following an operation for appendicitis. He was born in Hartford in 1864, and was graduated from the College of Physicians and Surgeons, Baltimore, with the class of 1896.

Dr. Robert R. McCandliss of Emporia, Kansas, died May 5 at the age of eighty-two years. He was born in Warren County, Ohio, and was graduated from the Miami Medical College. He served in the medical corps of the Federal army during the Civil War, and later went to Emporia, where he had practised medicine for thirty-seven years.

Dr. George W. Maston of Klamath Falls, Ore., died on April 25 at the age of fifty-seven years. He was a graduate of the Cincinnati College of Medicine in 1876. He practised in Albany, Ore., for a number of years, and removed to Klamath Falls in 1895.

Dr. H. C. A. Kirchner of St. Louis died May 3. He was born in Monden, Germany, in 1821, and obtained his degree from the Medical Department of Washington University in 1878.

Dr. M. L. Adams of Ballard, Wash., died in Seattle on May 1, of septicemia, following an operation wound. He was a graduate of the Medical Department of Vanderbilt University, Nashville, in 1881.

Dr. John Dutton Steele died at Philadelphia on May 17 at the age of forty years. He was graduated from Williams College in 1888, and from the Medical Department of the University of Pennsylvania in the class of 1893. He became a resident physician in the Philadelphia Hospital, and subsequently in the Presbyterian Hospital. He was associate in medicine in the University of Pennsylvania, physician to the Hospital of the University of Pennsylvania, and physician to the Presbyterian Hospital. He was elected a member of the Association of American Physicians at its recent meeting. He made numerous noteworthy contributions to the literature of diseases of the stomach and intestines.

Dr. Ernest R. Limbocker of New Virginia, Iowa, died May 3 of pneumonia. He was a graduate of Drake University College of Medicine, Des Moines, in 1905.

Dr. Horace M. Holmes of Adams, Mass, died May 6 at the age of seventy-eight years. He was a graduate of the Berkshire Medical College in 1852, and had practised in Adams for fifty-five years.

Anesthesia Commission.—A royal commission is to be appointed to inquire into the deaths under anesthetics in England and Wales. The records of these deaths for the years 1902 to 1906 inclusive were 148, 146, 154, 163, and 183.

LETTERS TO A NEUROLOGIST.

To which are appended brief replies purporting to set forth concisely the nature of the ailments therein described with remarks on their appropriate treatment.

V.

———, Va.
January 10, 1898.

Dear Doctor:—I have a patient who suffers from epileptic fits whom I am very anxious to cure, if possible. He has been to nearly all the doctors in this place and a few in Richmond, but he does not seem to have got much better. For the last year he has been taking a medicine supplied by a firm in Kansas City. If I could cure him it would be a great help to me, and I am writing to you to ask if you will send me a prescription for him. He says that every doctor that he has consulted has given him bromide of one kind or another, and that the patent medicine which he has been taking has the same effect as the doctors' prescriptions, only that it makes him more stupid, so he refuses to take any more bromide. I read in your book that there are a number of medicines that are substitutes for bromides, but you do not give any prescriptions, so if you will send me one I shall be very thankful to you and shall do all in my power to make him well. I enclose stamp for reply.

Yours truly,

———.

New York, December —, 190 .

Dear Doctor:—You will not, I hope, think me rude or unappreciative of your courtesy in consulting me, if, by way of reply to your letter of a few days ago, I send you a copy of a letter which I some time ago sent to the father of the girl whose husband's letter I also enclose. You will gather from it my attitude toward the treatment of this profound neurosis. I shall be sorry, indeed, if, after reading it, you are less keen on trying to get your patient well than you were when you wrote to me. Although epilepsy is, in the vast majority of instances, an incurable disease in the strict sense of those words, still there is scarcely any chronic disease that is so favorably influenced by appropriate treatment intelligently applied. I say to you frankly that before one can carry out such treatment, the idea that a prescription, even though its composition originated in the mind of a Minerva, can cure epilepsy must be at once dislodged, and in its place must be put a conception of the disease and a knowledge of the forces or factors that customarily precipitate an attack. The physician who essays to treat epilepsy, then, if properly charged with the seriousness of his task, will have a commendable measure of success.

Yours very sincerely.

———.

New York, December —, 1893.

Dear Sir:—I am of the opinion that your daughter is suffering from genuine epilepsy, *i.e.* epilepsy the disease and not epilepsy the symptom. I believe that she had her first attack when she fell from the horse; the epilepsy was the cause of the fall, not the fall the cause of the epilepsy.

The treatment of the disease epilepsy—congenital epilepsy, as it is sometimes called—is much more satisfactory when parents or those in *loco parentis*, or even the patient himself, have some idea of the nature of the disease. Examination of the tissue of the body after death fails to reveal any

structural abnormality, therefore we call it a functional disease, *i.e.* a disease in which function of the organ is disturbed without coexisting structural change in the organ. We physicians who know something about the profoundly intricate structure and delicate mechanism of the nervous system must content ourselves in our search for an explanation of this disease, with the theory that predicates an imperfect adjustment of certain components or constituents of the central nervous system, perhaps as the result of some jolt which these constituents received at some stage of their development as a tissue (histogenesis), or their development as a species (ontogenesis). In other words, we look upon genuine epilepsy as a sign of biological imperfection, of degeneracy, merely to indicate that certain things have transpired in the individual who is so unfortunate as to have this disease, which tends to throw him back to an original primitive type rather than direct him toward the type which is superior. A person thus constituted is less capable of resisting influences that are known to interfere with the perfect working of the nervous system, such as fatigue, indigestion, intoxication, etc., than the person who is normally constituted. It is for this reason that the important treatment of epilepsy is that which we often speak of as the moral treatment, or the disciplinary treatment. Epilepsy is much more successfully treated from this point of view than from any other. Empirically, we have learned of the value of certain drugs in its treatment, but the results obtained from giving them are most unsatisfactory unless the general plan of treatment of which I speak is adopted. Epilepsy is classed amongst the incurable diseases and very properly so, for the statistics from the most reliable sources show that only about five cases in a hundred recover. Appropriate treatment, however, materially assists the majority to a life of usefulness and productiveness. Nothing has brought this truth more conspicuously to the fore than the Colonies that have been established for the treatment of epilepsy in this country and abroad during the past generation.

The most important factor in the treatment of epilepsy is to determine the antecedents of an attack, and, having determined them, to avoid them. Anything that irritates the nervous system, anything that exhausts nervous energy, anything that disturbs emotional balance, emotional equilibrium, tends to produce attacks. The physician who searches every organ of the body to learn whether or not it may be the source from which exhausting sensory impulses are sent to the brain, who on finding them relieves them, is the one who will have the greatest success in the treatment of epilepsy. Such is the relief that sometimes comes from the correction of ocular inadequacies, the removal of nasal obstructions, relief of irritation connected with disorder of other highly sensitive parts of the body. Unfortunately for the reputation of our profession for mental balance, many physicians maintain that the disease epilepsy may be cured by such means, and this even face to face with the fact that although such claims have been put forward with great enthusiasm of energy for now nearly two generations, the prognosis in epilepsy has not been altered a whit during that time.

I should recommend that your daughter be put upon a strict dietary from which no article of food is rigidly eliminated save common salt and substances which are known to give her indigestion. I should allow her to have meat in small quantities once a day, and all recooked food should be avoided. I should not rigidly proscribe tea and coffee, but the less of these that are taken the better. Of more importance than the quality of the food is the quantity and the way in which it is taken. Practically any food may be taken if the patient masticates it thoroughly and slowly. This is a sure way of avoiding overeating. It should be the duty of some one of the family to see that not only there is a movement of the bowels daily, but that it is an adequate amount. My advice, therefore, is to avoid indigestion, constipation, and fatigue, as these are the forerunners of epileptic attacks in the vast majority of instances. If this is done, and if careful attention is paid to the diet, there will be very little difficulty in maintaining the equilibrium of nutrition which shall be manifest in good flesh, warm extremities, and equable spirits.

The drug that is most beneficial in the treatment of epilepsy is one of the salts of bromine, and apparently one salt is about as useful as another. Some individuals tolerate the bromide of soda better than they do the bromide of potassium, just as some tolerate a green hat better than a brown one, and if your daughter should happen to be one of those who is able to take bromide of strontium better than she can bromide of potassium, it would be wise to give her the one that is adapted to her. This and the dose of bromide that is adequate to reduce the frequency of the attacks, can only be determined by a careful physician, and with that end in view I shall write your doctor, giving him a detailed account of how I do it in my own practice.

Finally, although you may not find very much encouragement in the first reading of this letter, which announces to you rather baldly that one of your beloved ones is the sufferer of a disease which is practically incurable, still I think you will find some consolation in the statement that the disease does not necessarily abbreviate the victim's life nor materially interfere with her usefulness except in one direction. It is my profoundest conviction that patients with genuine nervous and mental diseases of degeneracy, of which epilepsy, hysteria, and psychasthenia are the type, hesitate before they marry, and if they marry, they should not propagate. It does not seem to me that it should be denied the epileptic to live forever in the deep, deliberate bliss of matrimony, but I maintain it a self-imposed duty to which I daily bow the knee, to point out to sufferers from hereditary nervous and mental disease, that they have a capacity for cruelty which Borgia and Caligula would have envied, *i.e.* the creation of human beings whose life is foiled in every limb. We cannot run from destiny, but we need not necessarily enter cripples in a foot-race with the fleet and the clean-limbed.

Yours very sincerely,

———.

[THE HUSBAND'S LETTER.]

BUFFALO, N. Y., December —, 1902.

Dear Doctor:—I am writing to you about my wife who, you will remember, consulted you about ten years ago for the relief of a disorder which you pronounced epilepsy. My specific purpose in writing to you now is to get your judgment concerning the advisability of subjecting her to an operation upon her head which has been urged by a physician in Philadelphia who has never seen my wife, but her case has been described to him by one of our friends. I enclose you his letter.

You will recall that, briefly, the history of my wife's illness is as follows: She was considered to

be in the most robust health until her fifteenth year. One day while riding in the ring of the riding academy here, accompanied by a master, she fell from her horse and was picked up in a dazed condition. She thinks she lost consciousness, but she is not very sure of it, nor does she recall what transpired before she fell. There were no marks of any injury to her head. She had a bruise on the shoulder and on the leg, nor did she have any other bad effects, apparently, from the fall. About four months after this she had an attack in which she became convulsed in all her extremities, rolled her eyes up, frothed at the mouth, bit her tongue, wet her clothing, and lost consciousness. After she recovered consciousness, which she did in from five minutes to half an hour, she was drowsy and inert and remained in a semistuporous condition for several hours. Afterwards she gradually regained her normal state. She had had about ten of these attacks when she was first brought to you, and meanwhile she had consulted Dr. Ferrier, in London, Dr. Raymond, in Paris, and many other physicians. Your opinion then was that the fall had nothing to do with the causation of the epilepsy, and you outlined a plan of treatment for her, and sent a nurse to her home to see that it was properly instituted. At your suggestion she was examined by Dr. ————, who ordered her to wear glasses constantly, as she had far sight in one eye and astigmatism in the other.

You will recall that you were very much opposed to our marriage, and when we insisted upon it, you stated that it was your preference to have no further participation in the treatment of her condition. We married, and we have two lovely children, a boy six years old and a girl four, and apparently they are healthy children. My wife, however, has got worse, and I mean worse in bodily health, and now, unfortunately, she is becoming incapacitated mentally. I have had her under the doctor's care almost constantly since you saw her, and now I am in the last ditch. I really do not know what to do with her, although I am getting suggestions from every quarter. Some of her family insist that I employ an osteopath, and others do not understand my obstinacy in refusing to put her in the care of Christian Scientists, and as you see from the letter enclosed, members of your own profession do not await the solicitation of their aid, but offer it directly. The number of promises of cure that I get through the mail makes me feel that I am not doing my duty to my wife, for it is not possible that such statements could be made if they had no foundation in fact whatsoever.

You will think it strange that I am writing to you after what transpired ten years ago, but I am doing it because I have often recalled the explanations you gave me of the nature of her illness when, before our marriage, I called upon you in New York. I am not sorry that I married, even though our life since then has been one of almost constant struggle for health and there has been less of that "Sliding with open eyes through liquid bliss" than is common to the average marital state. If the children do not inherit this or some other nervous disease I am content with my lot.

I do not imagine that your advice will be particularly different from what it was ten years ago, but I should like a word of counsel as to what steps to take now, and a word of assurance if you can give it to me regarding the future life of my children.

Yours very sincerely,

————.

Correspondence.

OUR LONDON LETTER.

(From Our Special Correspondent

LINACRE PROFESSORSHIP—MALTA FEVER—RHEUMATIC AFFECTIONS—COMPLICATIONS—NOTES—OBITUARY.

LONDON, May 8, 1908.

THE Linacre lectureships at Oxford and Cambridge claim to be the earliest endowments of university teaching with the exception of one professorship in divinity. Established 400 years ago, the Linacre endowments have passed through periods of depression and their history well illustrates the changes of opinion as to such benefactions. New arrangements have just been completed concerning them under which one lecture is to be delivered by a distinguished scientist each year. On Wednesday the new plan was inaugurated by the delivery of the first Linacre lecture under the new scheme in the new museum of the Cambridge University by Dr. Osler, Regius Professor of Medicine at Oxford. He was introduced by the Master of St. John's. The lecture was illustrated with lantern slides. Dr. Osler also handed around a number of printed books bearing Linacre's name on the title page. He remarked that among the many ties by which the old universities of Oxford and Cambridge were linked together was the possession of the blessed memory of a group of men whose benefactions made them honored as much in one as in the other. Among these, the first in order and in scholarship, as well as the most distinguished, was Thomas Linacre. That St. John's should have invited one from Linacre's old university to give that first lecture manifested in the "sons of the prophets" the old courtesy of the fathers. At Oxford the history of the endowment had been less happy than at Cambridge, but Linacre's name was associated with a much more important foundation, the Royal College of Physicians of London, of which he was one of the founders and its first president, and to that he left the example of a life devoted to learning, to medicine, and to the interests of humanity.

At the Medical Society of London on the 27th Colonel D. Bruce read a paper on Malta fever in which he described the work of the commission sent by the Royal Society at the request of the Government to investigate the disease. Their experiments seemed to show that the *Micrococcus melitensis* of Bruce, the efficient cause of the disease, entered the body in infected food or drink. Following this line of investigation, it was discovered that the goats in Malta were the reservoir of the virus, and goats supply practically all the milk consumed. Yet inoculating and feeding with the micrococcus gave no result at first. No rise of temperature, no sign of ill health was observed in the animals; they seemed to be in no way affected, and there was danger of the investigation lapsing, when it was accidentally noticed that the blood agglutinated the micrococcus. Some months later the matter came up again, and as a precaution to some experiments the blood of the animals was examined. To the surprise of the commission some specimens reacted to the agglutination test, and further experiments led to the discovery of the organism in the blood, urine, and milk. Thousands of the goats in Malta were then examined; 50 per cent. reacted and actually 10 per cent. were excreting the micrococci in their milk. Monkeys fed on the milk at once took the disease. A confirmation of the result occurred in 1905 when a steamship shipped sixty-five goats for America, and the crew who drank their milk took the fever and on arrival the organism was found in the milk of several. In Malta in 1906 the goat's milk was forbidden in the dietary of the garrison, and forthwith the fever ceased. The next year seven cases occurred, but were traced to the drinking of goat milk. We may protect the soldiers by strict exclusion of milk, but it is different with the population. There are no signs of an animal being affected, and the only effectual preventive is to exclude the milk, but the people are not prepared to give it up and no effort has been made to compel investigation with a view to destroy the infected animals. Colonel Bruce has not heard of the slaughter of a single goat, and the Maltese goatherd is still leading about his infected animals and selling their milk, which may be termed an emulsion of *Micrococcus miletensis*.

As to treatment, no specific has been discovered and the doctors can only treat symptoms. Antisera had been tried, but without success, and the injection of dead micrococci had proved equally useless. Some re-

sults had been reported and Colonel Bruce had often noticed statements in the medical journals which he believed to be inexact. He could find no proof that the disease was modified by such injections, even when controlled by the opsonic index. In reply to some questions, Colonel Bruce said goats had been found to be infected in other countries, notably N. W. India and the Orange Colony of South Africa.

At the conclusion of this meeting the president (Dr. Kingston Fowler) announced that the Fothergillian gold medal had been awarded to Sir A. Wright for his work on opsonins.

Rheumatism in some form is so common that every practitioner seems to meet with it daily. Its manifestations, or, rather, the symptoms attributed to it, are so numerous, so diverse, and so inexplicable, that an exchange of views about it is always interesting. Last month the Hunterian Society devoted two evenings to a set discussion on the subject. It was opened by Dr. Frederick Taylor, who looks upon the disorder as almost certainly microbic, though, of course, he admitted that this explanation, like all others that have been advanced, did not satisfy every one. Nor is that to be expected until rigid proof of the specificity of an organism is forthcoming. Chorea, he said, was a toxic rather than a purely nervous disease, and belonged to the infectious group, as shown by the occasional complication of endocarditis when there had been no rheumatism previously. Many forms of infective arthritis are associated with tonsillitis or various erythemata, but they might be due to some other toxemia than that of acute rheumatism. Wright considered that hemorrhagic, erythematous, and urticarial lesions were often due to deficiency of calcium salts in the blood, but it may be questioned whether they are manifestations of rheumatism at all. The relationship of acute and chronic rheumatism has yet to be cleaned up. The latter is to be seen in thousands of people who have never had the former. Endocarditis was always limited to the valves, unless the organisms reached the other parts by direct contact or extension, as in malignant endocarditis. Hyperpyrexia was a deeply interesting complication and prevailed like an epidemic from 1873 to 1877. Though the salicylic treatment was introduced it was not perhaps fully pushed in that period. In the eighteen years, 1888 to 1905, the admissions to Guy's Hospital for acute rheumatism were 1,887. Among them there were only seven cases of hyperpyrexia, of which two were fatal. As to salicylates, he considered 20 grains every four hours the best dosage. Carditis he thought as prevalent as ever, and would like to hear if others had found it less frequent than it was formerly said to be. He disagreed with the idea that carditis could be controlled in rheumatism. It might occur fifteen or twenty years after an attack of acute rheumatism.

Dr. Poynton stated the conclusions which he and Dr. Paine had formed from their joint researches, which extended over ten years. He said they had isolated a diplococcus from many parts of the body and it could be obtained in pure culture from the lesions of the disease, could cause similar lesions if injected into animals, and from these lesions could be isolated again in pure culture. He showed specimens from these lesions in animals. He and Dr. Paine were the first to produce pericarditis and endocarditis experimentally. They had often done it.

Dr. Horder was rather sceptical, as he had only had negative results, but in malignant endocarditis he had succeeded. Most microorganisms were streptococci, though some might be termed diplococci. They came from the alimentary canal and were not extremely virulent. They might be met with in syphilis, gonorrhea, or endocarditis when there had been no previous rheumatism. He held that the cause of rheumatic fever has not been discovered, and bacteria found in the disease were secondary. In investigations he had carried out with Dr. Andrews on some specimens, they found the reactions of *Diplococcus rheumaticus* identical with those of streptococci from cases of malignant endocarditis.

Dr. Luff declared that for every case of acute rheumatism the general practitioner would see 100 chronic, so called. This name was not fortunate, for it was really fibrositis, as Gowers called it. It was often started by cold or wet or strain. Salicylates were useless except to relieve pain, and for that he advised heat; for the fibrositis itself large doses of iodide of potassium. It was not necessary to diet these chronic cases, and it was time to dismiss the fetish of uric acid, which was only a harmless by-product.

Dr. F. J. Smith thought there was no difference between malignant endocarditis and other unless one of degree. He held further that every endocarditis was ulcerative.

Dr. Grunbaum thought more evidence was required to prove a difference between the organism of Poynton and Paine and that of Horder and Andrews. It was important in both cases to remember that a terminal invasion occurred in many diseases. Were cultures obtained late in the course of the cases? In reply to this, Dr. Poynton said some of the patients survived for years.

Dr. Seymour Taylor said in severe chorea there was often a rise of temperature, and in 30 per cent. of cases there was heart complication. Further, the disease was cured by salicylates as quickly as by anything. A child in his clinic with chorea and no history of rheumatism, had been treated by lumbar puncture and Poynton's diplococcus was found. Salicylate of sodium was given and recovery rapidly followed.

Manchester University has decided to appoint a second professor of medicine. The present professor, Dr. Graham Steell, will take the chair of Clinical Medicine, and Dr. George R. Murray, F.R.C.P., has been appointed to that of Systematic Medicine. Under an agreement between the university and the Royal Infirmary, Dr. Murray will become a member of the staff of that hospital when he takes up the professorship at the beginning of next session.

Our venerable leader, Sir Samuel Wilks, now in his eighty-third year, underwent an operation on the 1st inst., and every one is delighted to learn that it was successful and that he is doing well.

Dr. E. H. Lloyd, retired Brigade Surgeon, died suddenly from heart failure on Sunday in his seventy-third year. He joined the army in 1859 and retired in 1875. He served in the Nile expedition in 1884-5 and was in charge of the field hospital at Kaibar.

Dr. Theodore Duka, F.R.C.S., M.D., Knight of the Iron Crown, a retired Lieutenant-Colonel I. M. S., and formerly in the Hon. E. I. Co.'s service, died on the 5th inst. in his eighty-third year.

THE GERMAN SURGICAL CONGRESS.

(From Our Special Correspondent.)

DISINFECTION OF THE SKIN—ACROMEGALY CURED BY OPERATION—THE BLOOD IN BASEDOW'S DISEASE—SUBCUTANEOUS REMOVAL OF TUBERCULOUS GLANDS—RESECTION OF THE AORTA—OBLITERATION OF ARTERIES BY GRADUATED COMPRESSION—RESECTION OF THE ESOPHAGUS—INTRATHORACIC OPERATIONS—CHONDROTOMY IN APEX TUBERCULOSIS—ELECTRICITY IN THE TREATMENT OF CANCER.

BERLIN, May 1, 1908.

THE twenty-seventh annual meeting of the German Surgical Association took place in Berlin on April 21-24, 1908. V. Brumm of Tubingen spoke on the second day of the proceedings on the "Modern Improvements in the Disinfection of the Skin." He said that all the methods recommended for such disinfection were tested in his clinic, and the conclusion was reached that the best method is one that leads to the least injury of the skin. Disinfection by alcohol alone fulfilled this requirement better than any other technique. For the sterilization of catgut Dr. Chlumsky of Cracow recommended the following formula: Camphoræ trit. 60, phenol 30, alcohol absol. 5.

Hochenegg of Vienna read a paper on "A Case of Acromegaly with Tumor of the Hypophysis Cured by Operation." His patient, a girl, began to suffer from intense headache and disturbances of eyesight five years ago. These symptoms disappeared, but one year ago typical phenomena of acromegaly were noticed, the *x*-ray picture corroborating the diagnosis of tumor of the pituitary body. An operation for the removal of the tumor was done, it being reached by way of the nose; the growth was removed by means of a curette, and the wound wiped out with a sterile swab. The drainage tube was removed on the eighth day. As a result of the operation the headache disappeared, and the disturbances of eyesight are very much diminished now, two months after the interference. By the tenth day of the operation the teeth, which previously were separated from each other by a space of about one centimeter, approached each other closely. The feet and hands were becoming smaller in size. The patient was shown at the meeting and appeared to be in perfect health.

In the afternoon Kocher of Bern read a paper on the "Blood in Basedow's Disease." He said that an increase of lymphocytes could be found in most cases of

exophthalmic goiter. Collections of lymphocytes were likewise found in the preparations of the goiter. The coagulation of the blood was much delayed, the viscosity was increased. These data were obtained from the examination of over one hundred cases. Status lymphaticus or hyperplasia of the lymph glands of the body was of serious prognostic import in exophthalmic goiter as in other diseases; in this stage of the disease the treatment with the *x*-rays and the administration of arsenic were especially useful. In the discussion of the paper Hocnicke of Dresden said that the cause of the goiter was to be found in the hyperplasia following the diminution of function of the thyroid gland. To prove this experimentally, the speaker said that he had removed one-half of the thyroid gland in young rabbits, and this was followed within one or two years by a marked hypertrophy of the remaining half of the gland.

Dollinger of Budapest spoke on "The Subcutaneous Removal of the Tuberculous Glands in the Neck." He had recommended this method of dealing with the disease to the congress at its meeting five years ago. Now he presented the results of over two hundred operations, 167 of which were followed by primary union; the others resulted in cures after a suppuration of from one to three weeks' duration. In no case was any extensive suppuration observed. Experience has enabled him to diminish the time of his operation from one hour and a half to one-half hour. Braun (Zwickau) spoke of a "Successful Resection of the Aorta in a Case of Ganglion Neuroma." The patient was a child of six and one-half years, in whom a large, very movable retroperitoneal tumor was found on examination. During the operation by the transperitoneal route it was found that the tumor was easily shelled out in its periphery, but seemed more firmly attached in its center, pulling the aorta with it. In the attempts to free it from that vessel the aorta was torn; in consequence a piece of the vessel was resected and the two ends anastomosed. Uneventful recovery followed the operation. Examination of the tumor proved it to be a ganglion neuroma.

Doberauer of Komatau read a paper on "The Obliteration of Arteries by Means of Gradual Compression." He told of two cases of inoperable tumor, in one of which the iliac artery was exposed and slowly obliterated in the course of three days by progressive compression with the ligature; in the other case the same operation was performed upon the common iliac artery. In both cases after a few days the extirpation of the tumors was performed with resection of the vessels, yet the circulation in the limb affected by the resection was preserved. The technique of the operation may perhaps be found useful in cases of aneurysm. V. Hacker of Graz spoke of his method of "Resection of the Esophagus and Plastic Operation in Cases of Carcinoma of the Esophagus." His operation consists in the formation of a canal out of the external skin, the extirpation of the diseased part of the esophagus, and the interposition of the skin tube for the resected portion. A gastrostomy is performed before the operation upon the diseased esophagus. Neighboring organs are to be resected as completely as possible if they are involved. The operation is, of course, applicable only to the disease of the neck portion of the esophagus.

Küttner of Breslau spoke on the "Additional Experiences with the Operations Within the Chest Cavity." He has found that disturbances of respiration and collapse were completely obviated by the use of Sauerbruch's increased pressure method; even the presence of fluid in the lungs is perhaps not a contraindication. Experience with the use of diminished pressure in operation gave the same gratifying results in suitable cases. The increased pressure technique as recommended by Brauer is simpler, more aseptic, and more reliable than the method of Sauerbruch, and it is accordingly preferred by the speaker. Friedrich of Marburg read a paper on the "Operative Procedures in Unilateral Pulmonary Tuberculosis." The author laid special stress upon the anesthetizing of the patient, the rapidity of the operation, and the extent of the latter. He administered morphine before the operation and then proceeded with local anesthesia of the parts. Chloroform by inhalation was given only in the moments when severe pain was complained of, at most twelve grams of chloroform being used in the one-half hour taken up by the operation. An extensive thoracoplasty is called for by the operation, which creates a chronic pneumothorax, thus giving rest to the affected lung. Fever is usually reduced immediately after the procedure; the heart, on the other hand, goes into a species of delirium because of the effected dislocation of the thoracic organs. Energetic use of cardiac remedies is called for in this contingency. In three patients the amount of the sputum daily reached 150 c.c.; after the operation it was reduced to 15 c.c. The patients gained in weight after the procedure. The operation is especially dangerous from its effect upon the heart in cases of right-sided tuberculosis. In the three cases mentioned, all suffered from progressive unilateral affection of the lungs.

The same speaker demonstrated fine preparations illustrating the adaptation of the lungs to defects in volume. The experiments were performed upon dogs and showed the following: After the removal of a large portion or the whole lung, the other lung, the heart, and the diaphragm undergo transposition resulting in the complete obliteration of the created space.

Seidel of Dresden read a paper on "Chondrotomy in Apex Tuberculosis." He said that the diminution and the stiffening of the upper aperture of the chest may be looked upon as etiological factors in the production of the tuberculosis of the apices. He has therefore removed about one-half of a centimeter of the first rib in two patients suffering from tuberculosis of the apices. The incision was made through the rib from below and out upward and inward. A forceps could be used in executing the resection. The cases suitable for the operation are those occurring in adults possessing a narrowed upper aperture of the chest or a stiffened first rib. It is very simple in technique and leaves a condition much more favorable to the success of internal therapeutic measures selected to combat the disease.

Czerny of Heidelberg spoke of "Electricity in the Treatment of Cancer." He used the spark treatment according to the technique of Keating-Hart in many cases, and considers it of value only as an auxiliary measure. As the action of the electric current does not penetrate very deeply, the cancerous masses should at first be removed as completely as possible; only then the bottom of the wound is exposed to the action of the electric current, the poles being frequently changed, and the field being constantly cooled. In cases where the cancer cannot be removed the application of electricity has a favorable effect upon the pain, the bleeding, and the fetid secretion from the growth.

(*To be continued.*)

Progress of Medical Science.

Boston Medical and Surgical Journal, May 14, 1908.

A Study of the Value of Measurements of Chest Expansion.—H. W. Goodall and J. L. Belknap present tabulated material showing measurements made during the various phases of the respiratory act and measurements of both chest and abdomen with the patient at rest, inspiring and expiring. They believe that mensuration of the chest alone does not give an accurate measurement of respiratory capacity. To be of any value, corresponding abdominal measurements must be taken in order to determine, as nearly as possible, the position of the diaphragm, the chief respiratory agent. As much as 50 per cent. of the increase in chest circumference during maximum expansion may be owing to change in the shape of the thoracic cavity due to muscular contractions alone. From these two facts it is evidently erroneous to conclude from chest measurement alone that a supposedly healthy individual with a chest expansion of less than two inches has a diminished respiratory capacity, or that an individual with an expansion of two inches or more necessarily has a normal respiratory capacity.

The Extraintestinal Origin of Hydrobilirubin.—A. E. Austin and M. D. Ordway discuss the various theories of origin of urobilin and stereobilin which they regard as essentially identical, both coming from bilirubin. As a result of their own experiments and clinical observations, they advance the following propositions: (1) When no bile enters the intestine (absence of urobilin in feces and urine) urobilin may occasionally be found in fistula bile. (2) This is not due to the conversion of bilirubin to urobilin by the blood; what effect cells actively may have upon it we do not yet know. (3) It is evident that the liver does not form urobilin, or it would be oftener found when complete closure of the common duct occurs. (4) If urobilin is ever regenerated to bilirubin, it is probably not an oxidative process, as so often stated. (5) As cholecystitis is often accompanied by bacterial infection of the gall bladder, from which these germs may easily make their way into the liver and there exercise their functions as in the intestines, the query appears a just one, if the formation of urobilin other than in the intestine may not be due to bacterial infec-

tion. The authors regard their final conclusion as substantiated by the work of Adami who has demonstrated the presence in the liver of numerous bacilli.

New York Medical Journal, May 16, 1908.

Hysteria and the Reeducation of Dubois.—S. E. Jelliffe regards hysteria as a collection in an adult individual of primitive traits of psychological response to psychological factors. A primary trait of hysteria is instability. A second trait is the marked influence of suggestion, a third, negativism as a corollary from the second, and a fourth, the egocentric nature. Practically all physical signs result from the second factor of suggestibility. Moral causes play an important rôle in the development of the hysterical state. The moral education of man still rests in a large degree on the principle of authority transmitted by the Church; it makes the practice of duty depend on the fear of punishment and the hope of reward. It does not incite man to seek for pure and simple truth or to disinterested right-dealing; it does not develop sufficiently his judgment or healthy logic, necessary qualities for the formation of a high moral conception of life. It is this last which will permit man to pursue with serenity the end which he proposes in life, without selfish preoccupation and without discouragement; it is in this way that he will escape the depressing and dissolving action of the emotions, and that he will accept the inevitable with a healthy philosophy of life, and will not seek in the subterfuge of hysteria a remedy for his insufficiency, or a compensation for his disappointed hopes (Schnyder). Finally, if psychology is absolutely indispensable for the analysis of the mechanism of hysterical phenomena, it cannot in itself alone resolve the complex problem of the origin of the hysterical modification of mentality. To all psychological conceptions of hysteria, there must be associated a moral conception of it. It is chiefly this moral conception which ought to inspire all rational treatment of hysteria, such as has been indicated by Dubois in maintaining for the psychoneuroses a *moral treatment* in the highest sense of the word. The psychological analysis alone is but a step in the process toward reaching, from the therapeutic point of view, anything but partial results and the suppression of such and such symptoms. To get at hysteria in its very origin, one must penetrate more profoundly into the personality of the patient. He must be helped to reconstruct his mental synthesis on the basis of good logic, and to reconstruct his moral education, a complicated and often arduous task, but in Dubois's terms it is a true statement of the soul which no physician could repudiate to-day.

The Association of Tuberculosis of the Lungs With Diabetes Mellitus.—H. L. Shively reviews the extant literature on this subject, finding from it that the association is a frequent one and that in the early stages of this combination one or the other of the two maladies is often overlooked. In diabetes the pulmonary affection often runs an analytical course. The face may be cyanotic instead of pale. Cough is often slight and expectoration scanty. Sugar may sometimes be demonstrated in the sputum. Appetite may be preserved and even supernormal. There may be no fever, and sweating is rare. When phthisis develops in a diabetic polyuria and the sugar output are often both lessened. The recognition of the synchronous presence of both diseases affects the prognosis because it conditions the nature of the food and medicines which should be given. Administration of large quantities of fats and oils may hasten the onset of diabetic coma. A diet of meat, fat, cheese, and eggs is good for both diseases. Milk may often be permitted in diabetes, especially when sour or artificially fermented. The drug of greatest value in diabetes, opium, with its derivatives, codeine and heroin, is also indicated for the cough, the hemorrhages, the diarrheas, and to promote the euphoria of the advanced consumptive. The diabetic consumptive is very often afebrile, and for such cases exercise in moderation in the fresh air is not contraindicated. Such exercise is distinctly useful for the diabetic, as it has been shown that larger quantities of carbohydrates are tolerated on account of the increased consumption of sugar by the muscles during exercise. Creosote and guaiacol carbonate, which have continued in favor for tuberculosis, are also believed to relieve the symptoms of diabetes, notably the thirst and polyuria. Arsenic and strychnine, which have their advocates in diabetes, are good systemic tonics for the consumptive. Hydrotherapy is of undoubted value in both diseases, as are also the alkaline mineral waters, woolen clothing next the skin, abstinence from tobacco, freedom from worry and care, and a quiet life in the country in a mild, dry, and equable climate.

Transfusion.—From the comprehensive paper of G. M. Dorrance and N. Ginsburg, we abstract the following remarks on indications for this therapeutic measure: (1) For anemia due to acute grave hemorrhage, as from an accident, ruptured extrauterine gestation, or postpartum hemorrhage. In this variety the indication is clear and the results have been excellent. (2) Where chemical changes have occurred in the blood and the hemoglobin is not able to perform the interchange of carbon dioxide and oxygen; as in carbon monoxide poisoning and poisoning from synthetic analine compounds. Here the indication is positive and the results good if the operation is performed early. (3) In hemorrhage where the coagulability of the blood is deficient, as in hemophilia, cholemia, and in hemorrhage during typhoid fever. In hemophilia it will assist coagulation and with the other methods of treatment stop the hemorrhage, but of course will not cure the underlying cause. In cholemia transfusion will increase the coagulability of the blood and make it possible to operate without excessive hemorrhage. (4) In certain blood diseases where the blood forming organs are not sufficiently nourished to produce corpuscles or where the blood corpuscles are deficient in numbers; as in extreme chlorosis, secondary anemias, unclassified anemias of childhood, and in pernicious anemia. In these diseases the transfusion should be repeated if marked improvement or permanent results are to be expected. In pernicious anemia, if this method of treatment is contrasted with the other methods in use, one should be perfectly satisfied with marked temporary benefit. Full technical directions are given and summarized histories of six cases are given.

Journal of the American Medical Association, May 16, 1908.

Coagulation of the Blood.—A review of the history of the studies of the coagulation of the blood and of the views and theories in regard to the subject, is given by E. E. Robertson, G. M. Illman, and H. A. Duncan, who report their own experiments and observations on the coagulation time and the effects on it of calcium salts and other coagulants. They do not, as they say, attempt to deal with the more intimate physiological aspects of the question, but rather consider the alleged coagulants from the therapeutic standpoint. Their observations were made on 127 patients, largely typhoid cases, and Wright's technique was employed and is described. In addition to the coagulation time and calcium contents of the blood, the white blood corpuscles were also counted. Their results are summarized substantially as follows: 1. Coagulation is noticeably retarded during the febrile stage of infectious diseases. 2. The clinical use of the calcium salts has no direct or invariable effect on the coagulation time, either in large doses one hour after its administration or in small or large doses at any subsequent period. 3. The calcium content of the blood, as determined in terms of ammonium oxalate, proved unreliable in their hands. 4. Any definite relationship between leucocytosis and coagulation time could not be shown. 5. Nucleic acid uniformly failed to hasten coagulation or increase the number of the leucocytes. 6. The reaction of coagulation time to hemorrhage was conclusively demonstrated. 7. They were able to show that citric acid prolongs the coagulation time, and though the difference was not very marked before and after its administration, it seemed to lessen the viscosity of the blood. They advise its use in all conditions in which thrombosis threatens. This holds, they say, especially in heart disease with broken compensation and for a brief period in the convalescence from typhoid and even in pneumonia.

Catarrhal Deafness.—J. W. Jervey calls attention to adhesive bands and masses of lymphoid tissue in the fossæ of Rosenmüller as causes of catarrhal deafness. He considers them probably the residua, to some extent, of old adenoids. They interfere with the patency of the Eustachian tube, causing, besides the deafness, which may be severe or slight, tinnitus, cough, bronchial irritation, and almost always more or less postnasal catarrh. Vertigo, mental depression, and other nervous derangements may be produced. The diagnosis is easy with the rhinoscopic mirror. He treats these cases by breaking down the bands and granulations with the finger, after thorough cocainization, and after the slight bleeding has ceased, applying a solution of from 5 to 10 per cent. silver nitrate and repeating the application every forty-eight hours for ten days or two weeks. The results are excellent in relieving both the deafness and the other symptoms. Of course, the results are best in the more recent cases, and if a long-standing symptom, such as an irritative cough, has caused organic changes, immediate relief can hardly be expected, but the removal of the cause will surely pave the way for the cure.

Anastomosis of Hollow Viscera.—E. Wyllys Andrews, after noticing the advantages of the ligature methods,

remarks on certain drawbacks, especially the fact that they do not create an immediate opening and their tendency to pucker the visceral walls, and describes an instrument for rapid anastomosis that seems to meet these objections. It consists essentially in a forceps having blades equal to the length of the openings desired in the viscera, the blades being bodkin pointed, like the McGraw needle; after the preliminary suture they are clamped so as to crush the tissues and a slender chisel-pointed blade is thrust through the two grooves which form a sort of tunnel in the closed blades cutting a linear opening entirely through the walls of both viscera. The instruments are figured, among them a simpler and earlier form very similar to one devised by Flint, which might be called Flint's forceps. Care should be taken not to cut the encircling suture, and to prevent hemorrhage by careful deep suturing and avoidance of large arteries in choosing the line of anastomosis. The use of a heated cauterizing blade and the crushing action of the improved forceps minimize the danger, but suturing should not be neglected.

Unrecognized Fractures of the Hip.—A. Soiland reports three cases of unrecognized impacted fractures of the neck of the femur, one of them complicated by dislocation, which was reduced without disturbing the impaction. All were revealed by the Röntgen ray. He thinks such cases occur more frequently than is suspected, the shortening being so slight that it is not detected, and the injury is diagnosed as confined to the soft parts. He concludes, therefore, that it is not always safe to pass an opinion lightly on what appears to be a minor injury of the hip joint, especially when found in middle life or later. Examination under anesthesia can not always be depended on, and if sufficient force is used to produce crepitus, the results may be disastrous to the patient. The best way to determine the extent of the injury, and to remove all doubt in such cases is to make a Röntgen diagnosis which is possible almost everywhere.

The Lancet, May 9, 1908.

Spontaneous Rupture of the Heart.—The patient of A. T. Theobalds was an inmate of an insane asylum. He was 65 years of age, had chronic mania, but on the whole was fairly quiet and in good condition. One year previous to his final illness a mitral systolic murmur had been discovered. At the last, an attack supposed to be ordinary syncope came on. He soon recovered but died some five days later. At the post-mortem examination the pericardium was found to be distended with fluid blood; the heart was enlarged and weighed 375 grams. On the anterior surface of the left ventricle near the middle and to the outer side was seen a small subepicardial hemorrhage of about the size of a halfpenny, on the outer side of which was the external aperture of the rupture of about the size of a pin's head. On cutting through this the rupture was seen to extend from the inner surface of the ventricle and to be V-shaped. The wall of the ventricle was fully half an inch thick, but was pale, soft, and flabby. The coronary arteries, however, were apparently healthy. The mitral valve was dilated and there was slight thickening of the aortic valves, the first part of the aorta also being slightly roughened. The vessels at the base of the brain were markedly atheromatous and the choroid plexuses were calcareous.

The Precipitin Reaction in Hydatid Disease.—Experiments have been conducted by D. A. Welsh and H. S. Chapman at whose disposal has been hydatid fluids removed from nine different patients. Their conclusions are as follows: (1) The interaction between selected hydatid fluids and a sufficiency of the serum of a patient affected with hydatid disease has, in our experience of nine cases, never failed to give a positive precipitin reaction when tested before operation. (2) Not all hydatid fluids are capable of eliciting this reaction, and their failure is not associated with any noticeable diminution of their protein content. (3) Persistence of a marked reaction some weeks after operation probably indicates the continued presence of the parasite, but the disappearance of the reaction does not necessarily indicate complete removal of the cysts. (4) A positive reaction is independent of the site of the hydatid cyst (hepatic, peritoneal, muscular) and independent also of the nature of its contents (clear, turbid, or purulent).

The Operative Surgery of Labyrinthitis.—After a description of the surgical anatomy of the labyrinth, the author considers the related topics of guides to the vestibule and the course of the facial nerve in relation to the labyrinth and the middle ear. He next considers morbid anatomy and pathology and finally comes to operative surgery, the latter heading being illustrated by the summarized histories of various cases. He describes superior vestibulotomy, the same procedure with complete removal of the canals, inferior vestibulotomy, the same with partial or complete removal of the cochlea, double vestibulotomy, extirpation of the labyrinth, simple curettage of labyrinthine carries and sequestrotomy. In all 26 cases have come to operation in the author's experience. They have healed with such absolute uniformity that he has been led to believe that some at least of the failures after the radical operation may be due to disease of the labyrinth. In every case in which vertigo was present it was completely and permanently relieved. There has been no case of permanent facial paralysis. In only one case has there been a fatal result from operation. Two cases were lost from omission of the intervention on the labyrinth.

The Experimental Production of Gastric Ulceration by Injection of Gastrotoxin.—C. Bolton describes his experiments with reference to the development of a new theory of the pathology of gastric ulceration. Starting from the facts that specific bacteriolytic sera could be obtained which would destroy the bacteria against which they were formed, and that similarly hemolytic sera active against red blood corpuscles and in a few instances cytolytic sera had been produced, he conceived the idea of preparing a gastrotoxic serum active against gastric cells, thinking that this would throw light not only upon the phenomena of cytotoxic action but also upon the obscure problem of gastric ulceration. He succeeded in producing such a serum, the mode of preparation of which is described in full. He next describes the action of the serum when injected (1) in rabbits of serum made from gastric cells of the guinea-pig; (2) of cells from the rabbit into the rabbit and (3) of human gastric cells into the rabbit or domestic fowl. An analysis of the serum in the test tube is detailed and the specificity of the gastrotoxin discussed. The author says he has been able to prepare a serum which is active against human gastric cells. He concludes by saying that it would be premature to apply all those results directly to the explanation of human gastric ulcer, but they open up new lines of thought along which to prosecute further research. It is possible that not only certain endogenous but also certain exogenous poisons may be capable of initiating self-digestion through the blood stream, and that the production of such lesions may be facilitated not only by hyperacidity of the gastric juice but also by other bodies introduced with the food. It seems that all ulcers produced by digestion of dead or devitalized tissue are essentially acute and, since human gastric ulcer is commonly a chronic malady, it is not so much the actual mode of production which it is necessary to explain as the fact that the ulcer so persistently refuses to heal. It is possible that this chronicity may depend upon a secondary bacterial infection of the ulcer largely owing to muscular insufficiency, but upon the latter point the author hopes to be able to speak more definitely at a future date.

British Medical Journal, May 2 and 9, 1908.

Treatment of Bronchial Catarrh by Alkalies.—A. Haig refers to the use of salicylates in bronchial catarrhs. They are apt to fail when the urinary acidity is low, and as the effect of dyspnea is to increase the alkalinity of the blood and lower the acidity of the urine it follows that the salicylates will often fail in the time of greatest need, that is, when dyspnea is considerable and the heart is beginning to dilate. The author believes that this class of remedies acts simply as a solvent of uric acid. Following this matter up and believing that salicylates act in these cases merely as solvents of uric acid, it occurred to the author that the condition (dyspnea with falling acidity of the urine) which is unfavorable, to the solvent action of the salicylates would, on the contrary, be quite favorable to the solvent action of alkalies. He therefore began to try these older solvents of uric acid, with results which soon demonstrated that his conjecture was correct. He found that it was only necessary to give alkali in sufficient dose to render the urine alkaline to cause an immediate fall of temperature and speedy resolution of symptoms in many cases of bronchitis and bronchopneumonia. That to do this it was necessary to give alkali almost alone (say sodii bicarb. grains 20 to 60 for a child, or 90 to 120 for an adult in the twenty-four hours) and on no account to give ammonium with it, as this raises the acidity of the urine and has been proved by others to do harm in rheumatism. If a cardiac tonic is required digitalis can be used, but everything that raises the acidity of the urine must be avoided, and even such flavoring matters as orange and sugar, which tend to raise acidity, are better left out. If the alkali is going to do good, the temperature generally drops decidedly in from twenty-four to forty-eight hours, but it should not be given up as useless till the urine

has been rendered alkaline. After the temperature has been normal for one or two days, the author reduces the alkali to a small dose (gr. 10), and adds a little belladonna to dry up secretions, and the trouble is at an end. To sum up he lays down the following rules: (1) Give the alkali in sufficient quantity to make the urine alkaline; (2) avoid combining it with drugs that raise the acidity of the urine, or in fact with anything which acts as a precipitant of uric acid, such as lime, the metals or their salts, or even the chlorides, sulphates, or nitrates of the alkalies. Ammonium, so often given in these conditions, is one of the worst things to combine with the alkali, for it not only raises the acidity of the urine, but its urate is insoluble.

Outbreak of Beriberi on a Merchant Ship.—S. Roach refers to an outbreak occurring on a ship en route from Rangoon to Queenstown with 75 persons on board. The author boarded the vessel at the port of Ascension and found five cases of beriberi. The cargo was of teak-wood, which was stored away while wet and muddy, and became steamy and hot, thus favoring the outbreak of the malady from which one man died. Nothing in the sanitary condition of the vessel or quality or quantity in diet was found deserving of criticism. Lime juice was issued regularly. Rice was used sparingly. All drinking water was boiled. After the ship came to anchor five more cases of the disease appeared, and in fact the entire company were affected. One died of tuberculous meningitis. The remainder recovered.

Erythrocythemia and Cyanosis.—W. P. Herringham refers to the case of a woman of 38 years, with good previous history, except that six years before she had become anemic, which condition was followed by a heightened color and attacks of dyspnea in which she became very blue. The blood had been found polycythemic. She was placed in a hospital and two days later her dyspneic attacks came on again, the difficulty being chiefly in expiration and the severity being extreme. It suggested asthma but no râles could be heard in the bronchi. She died in about forty-eight hours. Autopsy showed that the lungs were emphysematous but small, and from the larynx to the finest divisions of the bronchi there was no sign of any disease of the air tubes. They were not thickened, and the mucous membrane was free from any secretion. There was a patch of congestion at the left base, where we had heard fine crepitation the day before death. The heart was rather small, neither hypertrophied nor dilated, and free from valvular disease. The liver was congested, but was not enlarged. The spleen was not enlarged, and seemed natural on section. The marrow of the long bones was not examined. Two theories suggested themselves as to the exact nature of the malady. One was that the case was one of atrophic emphysema in a youngish person which had led to polycythemia in compensation for deficient aeration; the other that it was a case of polycythemia or erythrocythemia of the usual type, but without any splenic enlargement, that the emphysema was a more or less accidental addition, and that the fatal dyspnea was chiefly due to the state of the blood. The author in closing discusses the question as to why these florid cases become blue on exertion. He suggests that in spite of the erythrocythemia, and in spite of the amount of hemoglobin, which has been sometimes as high as 180 per cent., there was less oxygen in the blood than usual. It seems possible that in this may lie the secret of the disease. Suppose for a moment that there is some fault in the cytoplasm or in the hemoglobin of the red cells which prevents them from being good oxygen carriers, or make the more likely supposition that there is some abnormal reducing agent in the blood which reduces oxyhemoglobin but does not turn it into methemoglobin or sulphhemoglobin. The want of oxygen might stimulate the bone marrow to form fresh cells, as it does where high altitudes or heart disease is the cause. This increase of the cells, erythrocythemia, may be in some cases adequate. There will then be much more blood in the body, but it will be fairly red, though each cell carries less than a healthy cell. These patients will be florid. In other cases increase in the red cells will not suffice. The fresh cells may be affected from the first with the same illness as the others, or the reducing agent may be of such power that they cannot counteract it. Then the patients will be blue. And whether they are florid or blue a little effort, by calling for more oxygen, will at once deepen the cyanosis. Even the florid patients will have very little margin. Such an explanation would not change the part ascribed to the bone marrow. Practically every observer who has examined the bones in these cases has called attention to the replacement of the natural marrow by erythroblastic tissue.

Some of the Uses of Peroxide of Hydrogen.—G. S. Hovenden commends the use of this remedy in carbuncles, inflammation of tendon sheaths, etc., applying the remedy on compresses, as well as syringing it into affected areas where such a procedure is possible. In the latter class of cases (tendon sheaths) it is of the utmost importance that the spread of the infection be checked at once: otherwise a permanent deformity may result, if nothing more serious happens. A compress use of the remedy diluted with water will often stop such processes in twenty-four hours.

Acute Fecal Impaction in the Rectum.—Three cases are reported by W. M. Robson. In the first, the conditions followed rectal feeding, required by severe hemorrhage from a duodenal ulcer; in the second, the condition followed an attack of diarrhea and vomiting; in the third a diarrhea with fever. The most prominent symptom in such cases is tenesmus, while they often have a spurious diarrhea due to catarrhal changes set up in the rectal mucosa by the presence of the fecal mass. The tenesmus is due partly to mechanical stimulation by the impacted feces and partly to the inflammation set up by their presence, and one condition aggravates the other. A lack of proper amount of water in the diet is often the cause of this rectal condition. A patient fed by the rectum does not absorb or retain enough fluid to meet his requirements. In diarrhea, extra fluid should be given by the mouth, and is well taken in the form of lemonade. A safeguard is to give a small quantity of some saline aperient which tends to prevent the absorption of too much fluid from the bowel. In all such cases, whenever tenesmus is associated with the passage of small quantities of fecal-stained mucus and pain on attempting to defecate, rectal examination should always be made.

Pyelonephritis in Pregnancy.—Herbert French says there are certain medical diseases for which pregnancy appears to make itself directly responsible. Pyelonephritis of late years has been recognized with greater frequency in pregnant women. It may easily be mistaken for something else. The milder cases may be regarded as simple pain in the back, as lumbago, as influenza, and so forth; severer cases may be thought to have pneumonia, pleurisy, or the like; the most severe cases may be diagnosed as appendicitis or as some other intraabdominal condition. The main symptoms of the disease are backache and pyrexia, with or without headache, vomiting, or rigors, and unless the urine is carefully examined for pus corpuscles the real cause of the trouble might readily be overlooked. The infecting organism in these cases is almost without exception the *Bacillus coli communis*. The pyelonephritis is not due to a cystitis, for in practically all the patients the bladder has been healthy, at any rate, at the beginning of the disease. There is frequently a dilatation of the ureter beginning one inch above the bladder. Evidently the sequence of events is this: Enlargement of the uterus; compression of the ureter against the brim of the true pelvis; consequent difficulty in the ejection of urine secreted by the corresponding kidney; infection of the urine retained in the partially obstructed ureter and renal pelvis; and subsequent spread to the kidney substance itself. The pyelonephritis of pregnancy would thus be comparable in some respects with pyelonephritis due to other causes, such as enlargement of the prostate in man; and just as in the latter case removal of the obstruction tends to cure the renal mischief, so does the birth of the child result in most cases in rapid amelioration and even complete cure of the trouble from which the pregnant woman has suffered.

Berliner klinische Wochenschrift, April 27 and May 4, 1908.

Local Sensitiveness of the Conjunctiva to Tuberculin.—Cohn says that a single instillation of one per cent. old tuberculin into the conjunctiva of nontuberculous persons does not produce a visible reaction, but results in an increased sensitiveness to the tuberculin. This new property of the tissue is shown by a visible reaction to a repeated instillation of the same substance and by the capacity to attract tuberculin injected into the blood and react with it. These phenomena are strictly local, being limited to the conjunctiva experimented with. They become manifest not earlier than five days after the first instillation, and, indeed, they are best developed only in the beginning of the third week. It is possible, though not at all proven, that such acquired sensitiveness of the conjunctiva is a sign of latent tuberculosis existing somewhere in the organism.

Sternal Pain and Tenderness.—Hampeln says that pain and tenderness of the sternum is a frequently observed phenomenon. Such sensation is usually located in the bone or its periosteum and not in the overlying soft parts, though in some cases it is a neuralgia affecting the sternal terminations of the intercostal nerves. The ultimate cause of this pain and tenderness is to be found

in repeated small injuries caused to the sternum by the clothing of the patient and his occupation. Often a constitutional weakness of the skeleton acts as a predisposing moment. The treatment consists in putting a stop to the injuries of occupation, if such exist, and in hydrotherapeutic measures, rest, and massage. In a few cases, mechanical support of the skeleton by plaster jackets, may be necessary.

Ophthalmotuberculin Reaction.—Rosenbach has tried the Calmette ophthalmotuberculin test in children suffering from various surgical affections. Of the twenty-eight cases with surgical affections other than tuberculosis, none gave a positive reaction; of five suspicious cases, two gave a positive reaction and three did not react. Sixteen of the nineteen children with tuberculosis clinically diagnosed gave a positive reaction, while three did not react. Two of the latter were in very bad condition; the third had a small tuberculous focus in the patella. In one case, the test resulted in a severe conjunctivitis which lasted over four weeks. Rosenbach concludes that positive test speaks for the presence of tuberculosis, while negative test does not exclude it.

Münchener medizinische Wochenschrift, April 21 and 28, 1908.

Pneumonia Caused by Friedländer's Bacillus Pneumoniæ.—Apelt does not share the opinion of A. Fränkel, that croupous pneumonia is caused only by the *Micrococcus lanceolatus*. He gives the histories of ten cases of pneumonia, in three of which Friedländer's *Bacillus pneumoniæ* was demonstrated in the sputum and in the blood during the life of the patient; in two cases it was recovered from an abscess of the lung complicating a pneumonia; eight cases came to autopsy, and all showed the presence of the organism in the blood or the organs. The author thinks that such pneumonias differ from the type due to the pneumococcus, by the usual absence of the initial chill and of herpes labialis and by higher mortality. The diagnosis may be made by the sputum, which is mucous in character and contains the characteristic diplobacillus.

Serotherapy in Infections with the Streptococcus.—Zangemeister says that the antistreptococcus sera obtained from horses and found protective for many other animals are completely useless in the experimental infections of apes, which can be rendered immune only by the use of sera obtained from closely related species. Therefore, the action of various horse sera may be successfully tried on apes because this animal, standing closest to man biologically, is just as refractive to such sera as the human being. In addition, the author has found that in several cases the use of horse serum has hastened the death of the apes experimented upon; it is to be remembered, therefore, that the damage done by the introduction of strange sera into human blood may outweigh the advantages due to their immunizing property.

Improvement and Simplification of Disinfection of the Skin.—V. Brünn says that the new principle in the disinfection of the skin consists in trying to prevent the transference of the organisms found on the skin to the operation field and not in the attempts to kill them by antiseptics. From this standpoint too much mechanical cleansing of the hands is to be condemned: it cannot remove the organisms, and only helps their transfer to the operation field by bringing them out of the deeper layers of the skin. Rubber gloves ought to be used to protect the field from the organisms on the operator's hand. The patient's skin is best treated by long application of alcohol, which shrinks the skin and attaches the organisms more closely to the tissues that harbor them. Ninety-six per cent. alcohol is used by the author, being applied by means of a sterile swab to the operator's hands and to the skin of the operation field. The results after three months' trial of this method compared very well with previous disinfection technique. The only disadvantage, the drying effect of alcohol upon the operator's hands, is overcome by the use of emollient preparations after the operation.

Deutsche medizinische Wochenschrift, April 16 and 23, 1908.

Pathogenesis and Operative Treatment of Prolapsus Recti.—Rotter says that prolapse of the rectum is due to the loosening of the structures which normally hold this portion of the intestine in place. These structures are the bony pelvis, the muscular pelvic floor, and the pelvic fasciæ. In prolapse the anal canal is widened, the pelvic floor takes on the position and shape which it normally has in the act of defecation, and the intro-abdominal pressure acts upon the sphincter ani independent of this act. In some cases the prolapse is predisposed by abnormal depth of the pouch of Douglas. In treatment of the condition the author has had most satisfaction with the operation of Rehn-Delorme, the technique of which he summarizes in the article. Of the three patients operated by him according to this method, two remained cured seven and eight months after the operation, one showed a tendency to recurrence of the prolapse.

The Practical Significance of Barberio's Sperm Reaction.—Fraenckel says that Barberio's reaction, which consists of the precipitation of microscopical yellow crystals when semen is mixed with saturated solution of picric acid, is not sufficient for the positive identification of human sperm. Similar crystals, though not in such abundance, may be obtained with other substances. Clinically, however, the appearance of numerous yellow, ovoid, or needle-shaped, strongly refracting crystals may serve for the identification of prostatic secretion and of human semen, especially in cases of azoospermia, where the diagnostic spermatozoa are absent. For forensic purposes the reaction has no value, and in any case a negative outcome does not exclude the possibility that the liquid under examination may contain human seminal fluid.

A New Operation for Old Fractures of the Patella.—Rotter says that in operating upon old patellar fractures it is often impossible to bring together the displaced fragments, because the quadriceps muscle has lost its elasticity. To overcome this difficulty he makes use of a long flap made out of the aponeurosis of the quadriceps muscle, the apex of the flap being above, while its base lies at the upper patellar fragment. This flap is turned down, so that its former anterior surface comes to lie upon the fragments and the patellar ligament. It is then sutured to the patellar ligament by numerous catgut sutures. Thus the contractions of the quadriceps can take effect upon the lower patellar fragment and extension at the kneejoint again becomes possible. A patient treated in this manner showed satisfactory result nine months after the operation.

The Movement of Tissue Fluids in Bier's Hyperemia.—Joseph and Schliep have studied the effect of Bier's hyperemia upon the movements of colored particles introduced into the tissues or into the blood. They say that such elements, if placed in the interstitial tissue, are normally transported to the spaces lying further in the lymph stream. The bandage used in hyperemia, on the other hand, stops this movement; any such elements in the hyperemic zone are forced to stop in the dilated lymph channels of the region. The edema caused by the hyperemia stands in close relation to the blood serum; substances introduced into the blood at any place and in any fashion appear in the fluid of the hyperemic edema. The elements that are found in the neighboring lymph channels are transported to the edematous region and are distributed uniformly and thoroughly through the tissues of the region. After a prolonged hyperemia the increased tissue fluids change the direction of their flow and send the particles contained in them towards the periphery, where they may appear in fresh wounds, if such are present. After the bandage is loosened, the particles are carried away with the tissue fluids. They are not to be found in the connective tissue spaces lying more centrally; indeed, the stream from the hyperemic area carries away with it other particles that have been placed into the connective tissue spaces at some distance from that area. In inflammation, the flow of tissue fluids is quickened from the beginning, and it carries the small elements very rapidly out of the inflamed area.

Treatment of Metritis by the Use of Cups Placed Over the Cervix, after Bier's Method.—F. Jaule and Robert Loewy recommend the use of a sort of speculum which is placed over the cervix and the contained air exhausted by means of a syringe, so as to produce congestion of the cervix after Bier's method. When the apparatus is in place the cervix becomes violet color and ulcerations blackish. If there is pus or mucous in the cavity of the uterus it is aspirated into the speculum, and a small amount of blood will flow from any ulceration. The sittings are given daily, or when much pain is caused every second or third day. Pain of a heavy character is experienced such as is experienced at the menstrual period, but it is not usually severe. The hypogastric region remains sensitive for some hours after the application. The method is recommended by the authors as applicable to all cases of metritis, whether simple or complicated with para-metritis or pelvic peritonitis. It removes all retained secretions. After several sittings have been given the pelvic congestion is lessened. Ulcerations are healed and entirely disappear and the progress of epithelialization may be followed.—*La Presse Médicale.*

Book Reviews.

Bier's Hyperemic Treatment in Surgery, Medicine, and the Specialties. A Manual of Its Practical Application. By Willy Meyer, M.D., Professor of Surgery at the New York Post-Graduate Medical School and Hospital; Attending Surgeon to the German Hospital; Consulting Surgeon to the New York Skin and Cancer Hospital, and to the New York Infirmary; and Professor Victor Schmieden, Assistant to Professor Bier, University of Berlin, Germany. Philadelphia and London: W. B. Saunders Co., 1908.

The Bier method of treating disease by artificial hyperemia has assumed a place of such importance in modern therapeutics that a work on this subject in the English language has become an absolute necessity. This book omits all theories on the subject, being practical in every sense of the word. In the short General Part the authors discuss the advantages of hyperemic treatment over other methods. Then they describe the two kinds of hyperemia—the passive or venous, produced by an elastic bandage or suction cup, and the active or arterial, produced by hot air. In the Special Part they mention all the diseases (surgical, medical, and those of the specialties) which can be treated by Bier's hyperemia, as well as the technique of applying the latter in each case. Excellent illustrations aid in the understanding of the text, so that one cannot fail to use the method correctly. The writers discuss at length those conditions in which sufficient experience has been collected to warrant a recommendation of the method, a short description only being given of those in which the treatment promises good results but has not yet been fully tested. Throughout the book the authors constantly emphasize the first underlying principle of Bier's method: "The blood must continue to circulate." This is a wise warning, as most beginners tend to overdo.

Outlines of Psychiatry. By William A. White, M.D., Superintendent Government Hospital for the Insane, Washington, D. C.; Professor of Nervous and Mental Diseases, Georgetown University; Professor of Mental Diseases, George Washington University; and Lecturer on Insanity, U. S. Army and U. S. Navy Medical Schools. New York: Journal of Nervous and Mental Disease Publishing Company, 1907.

The writer is one of our younger and up-to-date superintendents who stands for things "germanized" in the new psychiatry. The present volume is the first of a series of monographs, translations and minor text-books relating to nervous and mental diseases, to be brought out by the same publishers, and is in the nature of a text-book intended for the medical student. As such it answers a good purpose. The writer makes no claims to exhaustiveness, completeness or originality. Extended case-histories are omitted and there are no references whatever to other authorities who may have been consulted. On account of the very incompleteness of the work, such references would have been of assistance in looking up more extensively any particular subjects. The book opens with a rudimentary discussion of fundamental psychological processes. A chapter is devoted to defining insanity; and a chapter each to classification, etiology, treatment, general symptomatology and examination of the insane. The classification is essentially Kraeplinian. The chapter on examination is very suggestive in its completeness and based on the methods of some of the Germans. Paranoia and paranoid states, manic depressive psychoses, paresis, dementia præcox, involution melancholia, the senile psychoses, the infection exhaustion psychoses, the toxic psychoses, psychoses associated with other diseases, borderland and episodic states, and idiocy and imbecility, are discussed, each in a chapter, in the above order.

Étude Histo-Chimique et Cytologique des Crachats. Par le Dr. S. Israels de Jong, Ancien Interne Lauréat des Hôpitaux de Paris. Paris: G. Steinheil, 1907.

This brochure is a study on the examination of the sputum, and in it the author discusses in some detail each of the component parts, viz., mucus, sero-albuminous exudate, and the cells. The bacteriological study of the sputum and also its microscopical characteristics have received ample recognition at the hands of writers on the subject; but the study of the cells and exudate has often been neglected. The present work is an attempt to supply this omission.

The Blind-Deaf. A Monograph. Being a Reprint of the Deaf-Blind, with Revisions and Additions, by William Wade. Printed for Private Circulation. Indianapolis: Herker Brothers, 1904.

This is a book full of encouragement to those interested in any unfortunate deprived of the faculties of sight and hearing. The book is made up of a list of blind-deaf persons in this country and Canada, and a long list it is, who have been brought through the cultivation of the sense of touch into relation with the world and those in it. The degree of education to which these children attained varied, of course, with their natural abilities and with the ability of the instructor, but in the case of all, the progress made was astounding to those who do not know what can be done by patience and perseverance. The human mind is a wonderful thing, and this record of its triumphs over the loss of its instruments for communication with the external world is a most interesting and inspiring document.

Metabolism and Practical Medicine. By Carl von Noorden, Professor of the First University Medical Clinic, Vienna.

Vol. III.—The Pathology of Metabolism. By Carl von Noorden, H. Salomon, A. Schmidt, A. Czerney, H. Steinitz, C. Dapper, M. Matthes, C. Neuberg, O. Loewi, and L. Mohr. Anglo-American Issue under the Editorship of I. Walker Hall, Professor of Pathology, University College, Bristol, Pathologist to the Bristol Royal Infirmary. Chicago: W. T. Keener and Company, 1907.

The general character and scope of this treatise have already been indicated in the notes in these columns on the German original and on the first and second volumes of the translation. The present large volume of one thousand three hundred pages, corresponding to the second of the original, closes the work. It deals with metabolism as affected by the following conditions and agents: diabetes mellitus, gout, obesity, rarer derangements of carbohydrate metabolism, skin diseases, cancer, children's diseases, mineral waters, baths, disorders of the ductless glands, the rarer disturbances of protein metabolism, oxaluria, phosphaturia, drugs and poisons, light, Röntgen and radium rays, nervous and mental diseases, bone and joint diseases, and diabetes insipidus. In an appendix the analysis and caloric value of the commoner foods in the cooked and uncooked condition have been conveniently tabulated. The volume also contains the index to the second volume. The translators of the various sections have for the most part performed their tasks with judgment and have rendered the oftentimes very difficult language of the original text into smoothly reading English. The references to the literature have been brought more fully to date by the addition of recent contributions, particularly those of English and American writers. It is hardly necessary to say more than that the translation is the full equivalent of the original text, and that the editor and his collaborators deserve the greatest gratitude for having made this monumental work of reference accessible to English and American readers.

Anatomy of the Brain and Spinal Cord; with special reference to Mechanism and Function. For Students and Practitioners. By Harris E. Santee M.D., Ph.D., Professor of Anatomy in the College of Physicians and Surgeons, Medical Department, University of Illinois; Professor of Anatomy in Jenner Medical College, Chicago; Member of Association of American Anatomists. Fourth edition, revised and enlarged. With 128 illustrations, 33 of which are printed in colors. Philadelphia: P. Blakiston's Son & Co., 1907.

In this handsome volume the author sets forth the present status of the anatomy of the human brain and spinal cord. As stated in the preface "The special objects held in view throughout the book are the location of functional centers and the tracing of their afferent, associative and efferent connections. Particular emphasis is laid upon the origin, course, termination, and function of conduction paths as they are met in the regular study, and the more important and better known of these paths are summed up in a final chapter on the tracing of impulses. Function is everywhere correlated with structure; and so far as present knowledge permits, the function of each group of neurones is given in connection with its anatomical description." The book is divided into eight chapters, the first of which discusses the meninges of the brain; the second, is a general consideration of the brain. Chapter three is a dissertation of about two hundred pages on the cerebrum, with subdivisions on the forebrain, the midbrain, and the structure of the cerebrum; this is followed by a chapter on the cerebellum, pons, medulla, and the fourth ventricle. The next two chapters deal respectively with the spinal meninges and the spinal cord. The seventh chapter is on the tracing of impulses, and takes up in turn the efferent paths, afferent paths, and reex paths; and the volume concludes with a short chapter on the embryology of the brain and spinal cord. The book is well arranged, and conducts the reader by easy stages and in a pleasing way over a road that is too often made arduous and repellent. The illustrations are excellent, the table of contents and index are unusually complete and helpful, and the general get up of the book is all that can be desired. Readers and students in need of a work on this important subject are advised to inspect this volume.

Society Reports.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, Held April 27, 1908.

THE PRESIDENT, DR. J. RIDDLE GOFFE, IN THE CHAIR.

Optometry Bill.—The following letter was ordered sent to Governor Hughes: "Notwithstanding the protest of the Medical Society of the County of New York, whose membership amounts to about 2,200 practising physicians in the County of New York, and the protests of other medical societies and of the Opticians' League of New York State, Senate Bill No. 1033, introductory No. 320, has passed both Houses of the Legislature and is now presented to you for executive action. We, the members of the Medical Society of the County of New York, assembled this evening at our regular meeting, respectfully beg to enter again our protest against this bill becoming a law, believing it to be class legislation which would work an injury to the people of this State. The treatment of the eyes by glasses is unquestionably a part of the practice of medicine, and should these gentlemen desire to be licensed to this special work, we feel that the public should be protected by compelling them to conform to the laws now governing the licensing of all physicians of this State."

State Farm for Women.—Dr. E. ELIOT HARRIS, Chairman of the Committee on Legislation, offered the following resolution, which was seconded and passed: "Resolved, That the Medical Society of the County of New York petitions His Excellency, Charles E. Hughes, Governor of the State of New York, for his favorable action on the bill which has passed both branches of the Legislature, entitled: 'An Act to Establish a State Farm for Women' and making an appropriation therefor."

Custodial Asylum.—Dr. E. ELIOT HARRIS, Chairman of the Committee on Legislation, offered the following resolution, which was seconded and passed: "Resolved, That the Medical Society of the County of New York hereby petitions His Excellency, Charles E. Hughes, Governor of this State, to sign the bill which has passed the Senate and Assembly, entitled: 'An Act Making an Appropriation for the Purchase of a Site for the Eastern New York State Custodial Asylum.'"

Members and Dues.—The President announced that members whose dues or assessments for the current year were unpaid May 1, or who were under suspension, would not be eligible for nomination or election, or appointment for any official position in the Society, nor would they be entitled to vote or to receive the notices, publications, or privileges of the Society until their dues were paid. Any member whose dues or assessments for the current year were not paid before December 31 would thereupon cease to be a member of the Society. This was in accordance with the action of the Comitia Minora.

The scientific session was devoted to a symposium on obstetric prophylaxis.

The Hygiene and Management of Pregnancy, Including the Examination of the Urine.—Dr. AUSTIN FLINT, Jr., read this paper, and said that he would take up this subject in a general way from the standpoint of the general practitioner and try to emphasize those points which, in his experience, were often neglected. In recent years many important advances had been made in the management of pregnancy which were far-reaching in their results, for the welfare of both the mother and child. It was not too much to say that most of the complications of labor and the puerperium could be forestalled and the dangers materially lessened by proper prophylaxis. The management of pregnancy he divided into three periods of three months each. During the first period the ordinary rules of health should be followed and, under ordinary conditions, she should be allowed to lead her usual life without restrictions. Slight vomiting required no treatment as a rule; but if it was marked and persistent, the cause should be sought for. He recognized three distinct types of vomiting, the neurotic, the reflex, and the toxemic, the first being the most frequent type met with. This began, as a rule, about the sixth week and continued until the beginning of the fourth month. Regulation of the diet, removing constipation, and the administration of oxalate of cerium would ordinarily improve the condition. If the vomiting persisted, a pelvic examination, as well as an examination of the urine, should be made. The reflex type of vomiting was due to some pathological change of the pelvic organs, a backward displacement of the uterus being the most common. The toxemic type was more properly called pernicious vomiting, and often began as an ordinary neurotic or hysterical vomiting, the toxemic condition being secondary. The diagnosis was made by a chemical examination of the twenty-four hours' urine. Williams had shown that the ammonia coefficient in the first half of pregnancy varied between four and five per cent., but in toxemic vomiting it rose to ten, twenty, or even thirty per cent. So soon as the diagnosis of toxemic vomiting was made the uterus should be promptly emptied. The change in the nitrogen distribution in the urine was an absolute indication for an early abortion. A regular systematic examination of the urine should be made during the second period; this should be done every second week up to the last month, when the interval should be a week. The danger of the occurrence of eclampsia increased as pregnancy advanced, and the only way to be forewarned of danger was to insist upon regular examinations. Prophylaxis was productive of the best results during the third period, and pelvic mensuration should be the routine practice, being the only way that a diagnosis of pelvic contraction could be made. The importance of this could be appreciated only when one remembered that contraction occurred in from twelve to fourteen per cent. of all cases. About six weeks before the date of confinement, the patient should be examined; if the pelvic measurements were small, six weeks allowed ample time for interference. The size of the uterus, the quantity of amniotic fluid, and the size of the child's head should be estimated. Dr. Flint called attention to the work of Prochownik who applied the principles of dieting which he had previously used for the reduction of weight in adults, for the purpose of reducing weight of children born at term. The results were very favorable. This diet eliminated as far as was possible all fluids and carbohydrates, allowing proteids and green vegetables, but these only in limited amounts. Dr. Flint said he could speak well of the value of this measure to prevent oversized children, and so far he had never seen any ill effects from the use of this diet. An abundance of fresh air and walking exercises were of the greatest value, and nothing favored preliminary softening of the lower uterine segment and allowed the head to sink down through the pelvic brim as well as these daily walks. The patient should be instructed in regard to proper clothing. An abdominal binder or corset should be worn so as to hold the uterus up, and hold the long axis of the child in the axis of the pelvic inlet. Nursing was an ordeal which was justly dreaded by the mother when no attention was paid to the preparation of the nipples. The nipples should be painted over with a solution of tannic acid in glycerine every night, beginning about six weeks before the expected confinement. The clothing should be worn so as not to press upon the nipples. A regular examination of the urine should always be made, at least once a week for the first six weeks.

The Management of the States of Labor to Prevent Dystocia.—Dr. RICHARD C. NORRIS of Philadelphia said that the prevention of inertia, hemorrhage, and lacera-

tions were, in some respects, antithetical. For the first, the labor should be hastened; to avoid the second, it should be neither too rapid nor too slow; for the third the termination of labor should be retarded. Women differed so in strength, endurance, and quality of tissue that the actual duration of the first and second stages of labor had a very wide variation. When the amniotic sac was unruptured, a delay beyond twelve hours in the first stage of labor, associated with inefficient pains, was best treated by narcotics; this produced a sleep and allayed irritability. He had but little faith in quinine in the treatment of uterine inertia. Ergot he never used during the first or second stages of labor. When an edematous cervix was nipped between the head and symphysis a sterilized glycerine tampon should be held in contact with the lip of the cervix; this would cause the obstruction to disappear. Spasm, rigidity, hypertrophy, or cicatricial contraction, might be the underlying causes in a prolonged first stage and, once recognized, should be treated. If it was necessary to make Dührrsen's incisions, they should be made free enough to avoid uncontrollable lacerations when the presenting part passed through the cervix. It was his experience that next to a disregard of aseptic technique, the early application of the forceps before complete dilatation was the general practitioner's greatest obstetric sin of commission. When a forceps delivery was likely to follow, he chose the Pomeroy bag for primiparæ, for its efficient dilatation of the lower birth canal surpassed other means for that purpose, and the only drawback was the necessity for an anesthetic. As a rule, it might be stated that in primiparæ four, in multiparæ two, hours should be the maximum limit of the second stage of labor. He avoided the induction of deep anesthesia at the approach of the third stage of labor, preferring always to conduct the placental delivery with the patient fully returned to consciousness, the proper management of the third stage really consisting in the prevention of hemorrhage. When uterine inertia had characterized the labor, or when there was given a history of bleeding, a hypodermic injection of an aseptic preparation of ergot should be given just prior to the delivery of the infant. Immediately thereafter the hand should be placed on the fundus, but no attempt should be made to deliver the placenta for fifteen to thirty minutes, so long as there was a tendency to relaxation and hemorrhage. Manipulation predisposed to bleeding by dislodging clots. If hemorrhage occurred and persisted after the too early or unsuccessful resort to the Credé expression, aseptic ergot should be injected into the thigh, and the uterus at once invaded by the gloved hand to remove clots and placental masses, and to separate completely a partially adherent placenta. While a hot, sterile douche and appliances for the intrauterine pack were forthcoming, the vaginal hand should grasp the cervix, occlude it, and push it upward to forcibly make traction on the blood-vessels; the abdominal hand should force the fundus downward and forward over the symphysis to angulate the canal and further stretch and occlude the vessels supplying the uterus with blood. At the same time the ulnar surface of the abdominal hand might compress the aorta and vena cava through the abdominal wall. As a last resort the uterus might be packed with a large quantity of sterilized gauze, the tampon reaching from fundus to vulva. Inversion of the uterus he believed to be always preventable. The cardinal principle underlying every means to prevent lacerations of the birth canal might be expressed in the one word, dilatation. The prevention of uterine rupture that occurred during pregnancy from anomalies in the shape of musculature of that organ, so far as his knowledge went, was impossible. It was the neglected cases of obstruction that brought them their spontaneous ruptures; the unskilled operator, especially when he attempted a foolhardy version, was the cause of violent ruptures. Lacerations of the cervix were best prevented by securing naturally or through artificial means, complete dilatation. The application of the forceps before complete dilatation and its dynamic use to complete dilatation was only permissible to the operator of wide experience who knew the time required and the dangers incident to this method. Manual efforts at dilatation could not be compared to the efficiency of Pomeroy's bag. The tendency of its vaginal portion to be spontaneously extruded from the vagina and to drag downward the cervix, could be prevented only by holding it within the vagina during the distention of its vaginal compartment.

The Prevention of Maternal Infection.—Dr. Edwin B. Cragin read this paper, dividing his subject naturally into three periods of time, pregnancy, labor, the puerperium. The avenues of infection concerned the genital tract on the one hand, and the breasts on the other. Three possibilities of infection demanded careful attention, the use of vaginal douches with unclean nozzles by the patient, marital relations during the last weeks of pregnancy with husband unclean but not infected, and marital relations during the last weeks of pregnancy with husband infected with gonorrhea. Patients should be instructed not to take vaginal douches during pregnancy except by special order of the obstetrician and with special precautions. From many a case of infection following labor could the history be obtained that marital relations had been practised within forty-eight hours preceding labor. The three essentials to a clean vulvar field were an empty rectum, a closely clipped or shaven vulva, and a vulva cleansed with clean soap and water, the direction of the cleansing being from mons to anus. Sterile rubber gloves should always be worn by the doctor to safeguard against infection. Vaginal examinations should be made as infrequently as possible. Care should especially be taken not to carry infection by contact with the vulva not sterile to a sterile vagina. The presence of organic material, such as portions of placenta, membranes, and blood clots within the uterus so favored the development of a sapremia and perhaps a septicemia that Dr. Cragin said he desired to emphasize the importance of determining first, that the placenta and membranes had been completely expelled and, second, that the uterus remained so contracted that blood clots could not accumulate within it. The first object was gained by waiting a sufficient length of time for the uterus to regain tone before expressing the placenta, and this time was usually fixed at twenty minutes from the birth of the child. During this time the fundus of the uterus was gently held with just manipulation enough to prevent ballooning. If an examination showed the absence of any large portions of either placenta or membranes, infection would be avoided by carefully entering the uterus with the sterile gloved hand and removing the retained portion. Greater safety lay in the avoidance of the postpartum douche; there were two indications for its use, however, to check hemorrhage, and washing away débris that had been loosened by the finger. He believed the use of ergot had a special value as a supplement to, but not a substitute for, the holding of the fundus to maintain the contraction of the uterus. It was a good rule to suture a lacerated cervix immediately after labor only where there was excessive hemorrhage. The only way to use the catheter in the female was, with labia separated and meatus well exposed and cleansed, to pass the catheter directly into the meatus without touching the surrounding parts. The nipples should be bathed night and morning with a fifty per cent. solution of borax in alcohol. If the nipples were retracted, easy nursing and ready emptying of the ducts were favored by having the patient, during the last weeks of pregnancy, gently draw out the nipples with clean fingers at the time she bathed with the borax and alcohol solution. The care of the breasts and nipples during the puerperium implied cleanliness, support, and free drainage. To prevent abrasions the baby should not be allowed at the breast longer than

five minutes every four hours and only in the day time, until the milk was secreted. For the healing of cracks and abrasions the application of an eight per cent. nitrate of silver solution, followed for a short time by the use of a sterile nipple shield, had proven valuable in his hands. If the nipple continued to be tender and nursing painful, applications of glycerole of tannin would usually give relief. If mastitis threatened, the breasts should be emptied, the bowels moved, and ice applied to the breasts.

The Prevention of Fetal Infection; Eyes, Mouth, Umbilicus.—Dr. J. Clifton Edgar presented this communication. He said that cleansing of the infant's mouth immediately after delivery was especially called for after delayed or tedious labor and in cases of gonococcus infection in the mother. He did not believe there was any especial value in chemical antiseptics in mouth cleansing: the aim should be to remove mechanically any foreign substances as thoroughly and as gently as possible. Immediately after delivery of the head, the lips and nose were wiped free from mucus and foreign substances, and then the little finger was wrapped with a piece of gauze, dipped in boric acid solution or plain water, was passed into the child's mouth and any accumulated mucus, blood, or meconium removed by an outward sweep of the finger in each cheek. Each eyelid should be carefully cleansed by means of a piece of old linen and sterile water, or boric acid solution. Ophthalmia neonatorum caused from seven to ten per cent. of the existing blindness to-day. The midwife was mainly responsible for this condition. The gonococcus was found to be the cause of the infection in sixty per cent. of the cases. If at the time of birth, and before the eyes were opened, the lids were carefully and gently cleansed from within outward with gauze or absorbent cotton moistened in sterile water, and a separate wipe used for each eye, and if subsequently no pyrogenic germs were carried from the body to the eyes, ophthalmia neonatorum would be reduced to a very small percentage. If this was supplemented with a drop of a solution of one of the silver salts dropped on the cornea of each eye, the chances of the eyes escaping infection would be raised to the highest point. Which silver salt to use was still a debatable question. The early death of the infant without assignable cause should always make one suspect infection through the umbilical vessels. The cord should be handled as gently as possible and with clean hands. Sterile ligatures and scissors only should be used in ligating and cutting the cord. The raw stump should be covered immediately with a piece of sterile gauze and the infant wrapped in a sterile towel until the completion of the third or placental stage. A lubricant, and not a tub bath, should be used for the first cleansing of the child. The subsequent cleansing of the infant should be by sponging, and not by tubbing, until the umbilical wound had healed. In the tenement house service it was the routine practice to tie the cord with as little traumatism as possible, and after the baby had been greased with sterile lanolin and the vernix caseosa removed as thoroughly as possible, the stump of the umbilical cord was placed in a split-gauze dressing and the latter folded carefully over the stump; the binder was then applied and held in place by two safety pins. Unless the binder became soiled, it was left in place until the fifth day. In a series of 1,600 infants in hospital, including 1,000 cases in the East Side tenement houses and 600 in the hospital building, treated by this method, so far as known there had not been a single case of umbilical infection.

Dr. William S. Stone said that consultation in obstetrics was largely emergency work, limited to the latter part of labor, or for puerperal sepsis. A few years ago Dr. Stone had devoted much attention to a study of the relative size of the fetal head and the pelvis, a subject that had been treated with great indifference by his colleagues. He believed it to be worthy of more consideration.

Dr. Ralph H. Pomeroy of Brooklyn advised the use of the Pomeroy bags with discretion because of their great dynamic force and the consequent danger of lacerating the cervix. He called attention to the fact that detachment of the placenta occurred with uterine contraction; therefore he favored expressing the placenta, not after a wait of half an hour, but after the first reasonable contraction that occurred. In every case in which he had to enter the uterine cavity to extract the placenta, the interference to its expulsion was found to be due to retraction of the contraction ring, and not to any attachment of the placenta.

Dr. George L. Brodhead advised the constant observation of these patients, regulation of their diet, frequent examinations of the urine, and exercise up to the very day of confinement if possible. Many cases of dystocia could have been avoided, especially when it was learned that there was a small pelvis, if the patients had been properly instructed in regard to the diet. He believed the dilating bags should be more often used. There should be more external, and fewer internal examinations made; this would result in much fewer cases of sepsis.

Dr. John O. Polak of Brooklyn said that not sufficient attention was paid to the fetal mortality. He cautioned against tardy management. It was well to recognize early malpositions, especially the occipitoposterior positions, which were so frequently overlooked and so jeopardized the child's life. He never repaired a lacerated cervix immediately after delivery except in cases of hemorrhage. He believed that he had prevented cracked nipples by the use of boroglyceride. He now used ergot because it contracted and retracted the uterus and tended to prevent septic absorption.

Dr. Gill Wylie said that a good obstetrician should be a good gynecologist. Surgical principles should be applied in obstetric work, the same as after important surgical operations.

Dr. A. Ernest Gallant presented a method to keep the umbilicus aseptic, a method he had successfully employed during the past fifteen years. In a series of cases experimented on, not one developed jaundice or infection when the dressing was applied.

Dr. J. Milton Mabott said that the woman should be instructed to keep her hands away from the vulva after delivery. He reported the case of a woman who examined herself within twenty-four hours after delivery; she became pyemic and died as the result.

Dr. Richard C. Norris, Dr. Edwin B. Cragin, Dr. Austin Flint, Jr., and Dr. Johannes Pfannenstiel, Professor of Obstetrics and Gynecology, Kiel, Germany, discussed the papers.

THE PRACTITIONERS' SOCIETY OF NEW YORK.

Two Hundred and Seventeenth Regular Meeting, Held May 1, 1908.

The President, Dr. Robert Abbe, in the Chair.

Parenchymatous Nephritis, with Recovery.—Dr. Beverley Robinson showed this case. The patient was a longshoreman, 42 years old, a native of Ireland, married. He was a moderate drinker in the past. On October 5, 1907, he had a sudden and severe pain in the right side, which was made worse by deep inspiration and by coughing. That afternoon he was seen by Dr. Stanley D. Curran, who recognized the case as one of acute dry pleurisy. The pain subsided in a few days, and was succeeded by an effusion in the right pleural cavity. On October 20, 1907, he was sent to Bellevue Hospital, where he came under the care of Dr. Le Fevre. At this time the patient was suffering from shortness of breath, he was very weak and pale, with bluish lips and rapid and feeble pulse. The apex beat was displaced to the left. His feet, legs, thighs, scrotum, and abdominal tissues were markedly edematous, and his face

patient was a girl, nine years old, whose parents were strong and healthy, but the mother had been exceedingly and hands were also swollen. He was tapped at the hospital, 33 ounces of clear serum being withdrawn; the rest of the fluid was rapidly absorbed. He left the hospital on November 10 and returned to Dr. Curran's care. At this time the chest was clear, but there was still some edema. He was kept in bed on a restricted diet consisting of dry toast, zwieback, easily digested cereals, a raw egg now and then, and a little milk. Salt was restricted. His heart action was such that the use of digitalis was not indicated. The only drugs given were rhubarb and soda, and a diuretic mixture. Under this treatment the patient improved steadily. By November 25 his edema had entirely disappeared, and a week later he returned to his work as longshoreman. Up to the present time he had remained well, with the exception of a mild attack of lumbago. When his urine was last examined by Dr. Curran, on March 16, 1908, it was clear in color and contained but a trace of albumin; no casts. Formerly, it boiled solid, and there were numerous casts of all varieties. His lungs were free, but the vocal resonance and breathing sounds on the right side were diminished, due to the thickened pleura resulting from his former pleurisy. When the patient was last examined by Dr. Robinson, on April 26, 1908, the urine was acid and clear, amber in color, no deposit, no albumin. The breathing sounds were fairly good, and the heart was not perceptibly enlarged. There was a slight systolic murmur at the apex. Pulse, 84; regular. Blood pressure, 125 mm., taken by Dr. Norman Ditman. Dr. Robinson said he regarded this case as one of parenchymatous nephritis, probably of long standing, with interstitial changes in the kidneys. The case was remarkable in that the patient showed such rapid and decided improvement under adverse circumstances.

The Use of the Perforated Zinc Inhaler in Pulmonary Tuberculosis.—Dr. Beverley Robinson presented a man, 25 years old, who had been under his care for the past two years for pulmonary tuberculosis. When the patient first came under observation, there was consolidation of the upper left lung, and tubercle bacilli were found in the sputum. In addition to proper hygienic measures, and a sojourn during the past winter at Asheville, N. C., this patient, during the past year, had regularly worn at night a perforated zinc inhaler containing a mixture of spirits of chloroform, alcohol, and creosote, in equal parts. Under this treatment he had steadily improved. No tubercle bacilli could be demonstrated in his sputum at present, and an examination of his chest showed that his pulmonary lesion had apparently been arrested. Dr. Robinson said he was convinced that in this, as well as in other cases he had in mind, the inhaler was a very important adjunct to the treatment. He also called attention to the fact that a localized congestion of one or both vocal cords, associated with pronounced anemia of the rest of the larynx, was a very significant sign in the early recognition of tuberculosis. This condition may exist without symptoms, occasionally indicating laryngeal trouble, and may be evident when the tuberculin test is unreliable, as well as the *x*-ray. In his judgment every case of pulmonary tuberculosis should be examined with the laryngeal mirror and in many cases, whether the larynx was visibly affected or not, the perforated zinc inhaler should be worn almost continually at night, or day and night, for a long while. It took time to accustom some patients to its proper and efficient use.

Occlusion of the Inferior Vena Cava.—Dr. Walter B. James showed a man whose previous history was unimportant. His occupation was that of a stationary engineer, often working in damp cellars. About five years ago he began to have symptoms pointing to a femoral thrombosis of the left leg; subsequently, the right leg became similarly affected, and when he came under Dr. James' care at Roosevelt Hospital, both legs were swollen, and the patient complained of a good deal of pain in the deep muscles of the back. The superficial veins of the scrotum were markedly swollen, and there were huge varicosities covering the lower abdomen. The thrombotic condition in this case, Dr. James said, had apparently extended upward from the femorals into the iliacs, and occluded the inferior vena cava. In other respects the man was perfectly well, and was able to do his work. The case was of special interest when compared with the one which Dr. James showed at the previous meeting of the Practitioners' Society, a case of total occlusion of the superior cava resulting from pulmonary tuberculosis. It was a matter of great interest to notice that the individual veins which were enlarged were exactly the same in both cases; in other words, the same collateral circulation was developed in both patients through enlargement of the superficial epigastric and the internal mammary veins. In the first case, occlusion of the superior cava, the blood flow was all downward, while in the second case, occlusion of the inferior cava, the blood flow was all upward. In both cases the general visceral circulation was perfectly good. In the superior cava obstruction there was no edema of the lower extremities, while in this latter case the only troublesome feature which brought the patient to the hospital was very marked edema of both legs, with chronic persistent ulcers.

Melanotic Tumor of the Eye and Liver, with Symptoms of Acromegaly.—Dr. Lewis A. Conner showed this case. The patient was a man, 37 years old, who up to ten years ago had been unusually healthy and vigorous. He then developed symptoms suggestive of pulmonary tuberculosis, which lasted for seven years, and then ceased. Three years ago he began to have severe pains in left eye, and about the same time it was noticed that the left lobe of his liver was moderately enlarged. Since then there had been a slowly increasing exophthalmos of the left eye, and a steady growth in the size of the liver, which now was of enormous size, and almost completely filled the abdomen. The eye changes (which have been studied by Dr. C. W. Cutler) had been chiefly those of a retrobulbar growth, but there had been also a slightly elevated pigmented patch in the choroid suggestive of a beginning neoplasm, which had, however, shown little or no disposition to increase. During this time there had been a distinct increase in the size of his head, hands, and feet. This increase was altogether in the bony structure. The nose also had the characteristic appearance of acromegaly, and the lips were thick and prominent. The urine, upon the addition of some oxidizing agent, became black from the presence of melanin. An enlarged, hard lymph node removed from the neck showed the microscopic picture of typical endothelioma, but without pigmentation. Up to very recently the patient's general condition had remained good, although the disease had existed for three years, but at present he was losing weight rapidly and had frequent, profuse sweats, but no temperature. The association of the eye tumor, the enormous liver and the melanuria made it appear almost certain that the growth was a melanoma. This view was supported by the histological findings of the growth, since most of the so-called melanosarcomata were now believed to be of endothelial origin. The fact that no pigment was found in the gland metastasis did not negative such a view, as pigment was frequently lacking in such metastases. It was difficult to say whether the growth was primarily in the choroid, as was usual, or in the episcleral tissue behind the bulb, where normally pigmented cells were to be found. The condition of the eye suggested the latter as the more probable source of the tumor. (One such case had been reported by Achenbach.) As to the cause of the symptoms of acromegaly, one could only conjecture. The bitemporal hemianopsia so often seen in tumors of the pituitary gland was lacking in this case.

A Case of Extensive Myositis Ossificans and Osteochondroma.—Dr. Robert Abbe showed this case. The

nervous and disturbed during her pregnancy. The child was fed on modified milk (Holt's formula), and had suffered from frequent attacks of colic, with constipation, necessitating the use of repeated enemas. During her infancy it was noticed that bumps from striking her head on the crib always left hard ridges remaining for weeks, and that mosquito bites resulted in large swellings and blisters. As a baby, she had excellent muscular control of her head. She was late in learning to walk, about 20 months of age, and it was then noticed that she held her head forward and had an unusual number of falls and forehead bumps. It was also noticed about that time that she could not raise her head to look at the ceiling. When she was two years old, she had massage for the stiffened neck muscles, and a frame corset, with back pressure and a chin rest to hold the head erect. When she was four and a half years old, an orthopedist was consulted, who applied braces, and advised cod liver oil and hypophosphites. She developed a number of hard muscular swellings on the arms and neck, which came and went. In May, 1904, the movements of one arm became rapidly restricted; then the other was similarly affected. Her symptoms at this time were apparently more acute, and she suffered a good deal of discomfort. The muscular swelling, which had formerly been transient in character, now refused to disappear, and became hard and bony in consistence. When she was six years old the braces were discarded.. These hard swellings now involved the back, neck, and arms, and at infrequent intervals a small, new swelling appeared, but for the past two years the disease had shown but little activity. The child lived in the country; her surroundings were all that could be desired, and her general health was apparently excellent. About a year ago, Dr. Abbe said, he began the use of liquor ammonii acetatis and bicarbonate of sodium in the hope of inducing a solution of the excess of phosphate and lime deposits. More recently he had reversed his tactics, and given dilute mineral acids. At his suggestion, Dr. Russell H. Chittenden, who had taken a great deal of interest in the case, had conducted some interesting experiments in connection with it. He first tried withdrawal of the red meats and other foods rich in lime and phosphates, avoiding milk, and using cream, rice, sugar, fruit, and vegetables. After some weeks of this diet he made elaborate studies of the excretions, and found the nitrogen excretion low, with a large output of lime; fully as much as an adult man would excrete. The diet had apparently produced a noticeable elimination of calcium. He then tried a diet without carbohydrate food, using beefsteak, eggs, lettuce, fish, beef broth, spinach, etc. Under this, the output of nitrogen was very large, but at the same time there was a large increase in the output of calcium and phosphoric acid, and he called attention to the fact that the acidosis which resulted from a carbohydrate free diet carried off with it a fairly large amount of calcium. Dr. Abbe said he was inclined to regard this as a case of infectious myositis ossificans, originally starting in infancy in the deep cervical muscles, and after five years wearing itself out, after attacking successively at least twenty muscles, confined chiefly to the neck, back, and sides. The child had now apparently outgrown the active stage of the disease. Incidentally, the chondroosteal changes in muscle and cellular tissues were interesting. At this date it was probably now safe to operate if gain could be planned, without further advance in the disease.

Dr. Charles L. Dana said he recalled one case, in a man of 35 to 40, in whom exostoses, similar to those in the patient shown by Dr. Abbe, developed all over the body in early childhood and had remained unchanged. They were immovable and attached to the bones. He thought that some of those in the present case seemed like real exostoses.

Dr. Virgil P. Gibney said he had seen a number of cases similar to the one shown by Dr. Abbe, and he recalled one case in particular which he studied together with Dr. Janeway and the late Dr. Frank Hamilton. In that case, a typical one of myositis ossificans in a girl about ten years of age, the arms were practically useless until the ossified latissimus dorsi was resected. The scaleni were also involved. The case was reported at length in the *American Journal of the Medical Sciences*. Operation afforded decided relief, and did not cause any recurrence, as did removal of extensive exostoses in the case of osteoarthritis of the hip in a young woman under his care some eight or ten years ago. Brisement forcé aggravated the case, and growth of bone was most marked after every attempt to secure motion. Finally, an operation for complete removal was performed, and the joint was liberated. Within a few months thereafter great bony plates again formed, and the joint was again ankylosed, notwithstanding primary healing after so extensive an operation. Since then, in dealing with cases of osteoarthritis, he had learned to leave these bony growths alone, particularly when they were located about the hip joint. In cases of multiple exostoses, the tibia and upper end of the humerus and the clavicle were favorite sites for their development, especially in the region where the tendons were inserted. In the German army, cases had been reported which were attributed to the carrying of heavy muskets, and in some instances they were associated with a striking history of heredity. In the case presented by Dr. Abbe there was apparently a combination of multiple exostoses and mysositis ossificans.

Bronchoscopy.—Dr. Walter B. James reported the case of a boy, seven years old, who came under observation a week ago suffering from chronic bronchitis and asthma, which was intermittent in character. Upon subsequent examination, the physical signs of obstruction to the entrance of air into the left lung were made out, and upon questioning the boy's mother she stated that last Thanksgiving's Day he had bought a penny trumpet, and while playing upon the same he had accidentally inhaled the reed, and for several days after this occurrence the sound of the whistle in the chest could be distinctly heard. Upon receiving this information from the mother an *x*-ray was taken of the boy's chest, which plainly showed a foreign body, evidently metallic, lying in the median line, opposite the fourth dorsal vertebra, and pointing down to the left bronchus. Dr. Emil Mayer was thereupon asked to see the case in consultation, and he succeeded in removing the foreign body with the bronchoscope. The operation was completed in 13 minutes, without the slightest hemorrhage or any trauma. The foreign body was found lying at the bifurcation of the trachea, and after it had been caught by the clutch of the instrument it was found to be so large that it would not enter the bronchoscopic tube, and it was thereupon withdrawn together with the tube. The operation was done under chloroform, with the child's head thrown back, so as to straighten the trachea, and the straight bronchoscopic tube was then inserted between the vocal cords under the guidance of the light thrown into the tube. The boy, after five months of complete invalidism, was practically well 24 hours after the operation, and after a couple of days more went home cured, without either signs or symptoms of disease.

Melæna Neonatorum, with Report of a Case Cured by Transfusion.—Dr. Samuel W. Lambert reported this case. (See page 885.)

Philadelphia Neurological Society.

At a stated meeting, held April 24, Dr. Alfred Gordon demonstrated "A Case of Unilateral Descending Paralysis." The patient was a girl, about twenty-two years old, who, five years previously, had been seized with pain shooting down the right upper extremity, followed by gradually increasing weakness and wasting of muscles in the same member. Later, weakness and wasting developed in the right lower extremity also. The reflexes were increased

in both extremities on the right side and in the left lower extremity. There was, besides, difficulty in swallowing liquids, which when ingested returned through the nose. Further, the eyes exhibited nystagmic movements, principally in the lateral direction. There were no sensory changes and no disorder of coordination. The case was looked upon as one of anomalous multiple sclerosis. Dr. Francis X. Dercum demonstrated "A Case of Combined Brachial Palsy Associated with the Klumpke Symptom-Group." The patient was a woman, sixty-seven years old, who presented evidences of intrathoracic neoplasm, and who complained of intense pain in the right upper extremity, associated with weakness, and wasting, and marked reddish discoloration. There was also narrowing of the palpebral fissure and of the pupil, and an absence of sweating about the face on the same side. The case was believed to be one of secondary neoplasm of the spinal cord. Dr. J. H. W. Rhein reported "A Case of Exhibiting Agnosia Confined to the Left Hand." Tactile, painful, thermic sensibility, the sense of position and of location, were preserved, as well as the recognition of size, shape, dimension, and density, but there was loss of the power of determining the identity of the object by touch. There was no sign of paralysis, ataxia, apkasia, or spasticity. Dr. T. H. Weisenburg exhibited for W. J. McConnell a young man about twenty-seven years old, with a history of syphilis, who showed an ability to rotate either eye outward independently of the other eye, with the development of diplopia. Dr. M. D. Bloomfield exhibited a man, about thirty-five years old, who presented a somewhat irregular clonic convulsive movement of the right upper extremity, which had been present for a period of eight years, shortly after singing before a group of persons. The movement ceased during sleep, and returned in the morning as soon as the patient began to think of it. He was able, in spite of his disability, to play pool, to swim, to shoot, and to do other things requiring good coordination. The manifestation was looked upon as an hysterical one. Dr. Bloomfield exhibited also a man who had been successfully operated on for carcinoma of the stomach, recognized from a study of the so-called Head's lines and zones, although other methods of diagnosis had failed to establish the existence of the morbid condition. Dr. W. B. Cadwalader presented a communication, entitled, "The Pathology of Acute Anterior Poliomyelitis." From his studies, he reached the conclusion that poliomyelitis was merely a variety of myelitis in which especially the ganglion cells and the gray matter of the anterior horns were involved, although the white matter did not escape, and sometimes the posterior horns also were involved. Dr. Charles W. Burr reported "A Case of Prefrontal Tumor," and presented the specimen. The case was remarkable on account of the short duration, lasting in all eight weeks from the initial loss of consciousness, which ushered in the acute symptoms, although dull headache had been complained of for a short time previously. The patient was a woman, thirty-eight years old, found unconscious upon the street and taken to a hospital, where soon she recovered. In the course of five weeks acute bilateral choked disc developed, and death took place suddenly in an attack of loss of consciousness, without premonition. There were no motor, sensory, or mental symptoms during life. Autopsy disclosed a large tumor in the prefrontal region, displacing but not invading the brain structure. Dr. J. Hendrie Lloyd exhibited "A Tumor of the Parietal Region." The patient was an old Russian woman, presenting symptoms of left spastic hemiplegia. On account of the difficulty of communication, no history could be obtained. After death, an easily enucleable tumor was found situated in the fissure of Rolando, and exerting pressure on the ascending frontal and ascending parietal convolutions. Removal could readily have been effected during life. Dr. Tom A. Williams reported "A Case of Partial Crossed Hemiasynergia." Dr. M. D. Bloomfield presented a communication, entitled, "Epicritic and Protopathic Sensory Pathways." He recited several cases in which a diagnosis was reached from a careful study of Head's lines and zones; that is, areas of hyperesthesia on the surface of the skin that have been found to correspond with the distribution of nerves related to the intra-abdominal and intrathoracic viscera.

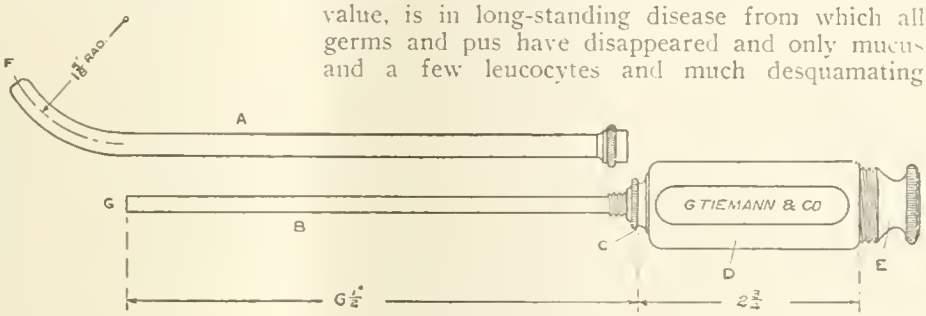
AN OINTMENT-APPLICATING SOUND FOR THE MALE URETHRA.

By VICTOR C. PEDERSEN, A.M., M.D.,

NEW YORK.

GENITOURINARY SURGEON TO THE OUT-PATIENT DEPARTMENT OF THE NEW YORK HOSPITAL AND HOUSE OF RELIEF, HUDSON STREET HOSPITAL.

The use of ointments in the various passages of the body is not a highly successful procedure and yet there are cases occasionally met with where a salve is an excellent means of temporarily changing the treatment, which sometimes will result in great benefit. The only type of urethral case in the writer's observation in which salves are of value, is in long-standing disease from which all germs and pus have disappeared and only mucus and a few leucocytes and much desquamating epithelium make up the shreds. It will not succeed in all of these but it is worth the trial.



The Ointment-Applicating Sound.

The type of salve used is of next importance. It must be thin enough not to constitute a foreign body of resistant or irritating elements. As the foregoing condition is purely catarrhal, glycerin must be one important constituent and ichthyol seems to be another desideratum. For absorption, lanoline is a good base thinned down with alboline. The salves which the writer is employing are as follows: For purely catarrhal cases, ichthyol 1-5 part, glycerin 10 parts, liquid alboline 10 parts, lanoline 40 parts. Instead of the ichthyol, 2 parts of argyrol or 6 parts of argyrol may be substituted if astringency seems desirable. The ichthyol salve in various strengths seems to be the best of the three.

The first desideratum of the applicating ointment sound must be that the salve be deposited thinly and evenly in the urethra without any injury to the mucous membrane. For this reason the ointment-applicating sound which my late colleague, Dr. Walter D. Trenwith devised and was about to publish just before his death was faulty. It consisted in a sound with a small opening, so small that it was impossible to press the salve out without having the deep urethra bleed by the irregular motions of the tip of the sound in the effort. A

salve thin enough to correct this difficulty was practically a fluid and lost the characteristics of an ointment.

The writer has taken a standard type of sound size 20 F. (see A in the diagram) with a beak of standard curve but shortened by one inch. The edge of the tube is rolled in a little at the beak to make the instrument painless in passing. At the other end of the sound is a hub and female screw to permit fastening the sound to the rest of the instrument.

The next detail is the inner or delivery tube (see B of the diagram), consisting of a straight smaller tube passing through the hub to the base of the curve of the sound, thus permitting the salve to be delivered only into the curve of the sound itself. This is important because it permits more readily the cleansing of the sound and also changing of the salve with the smallest amount of waste. A hub is attached to the base of this inner tube bearing a male thread on each side of a knurled flange. On the sound side of the knurled flange the thread passes into the hub of the sound as just described; while at the other side of the flange the ointment carrier is attached. The length of the straight part of the shaft of the sound (A) and of the delivery tube (B) is 6½ inches. The hub of the delivery tube is indicated at (C) of the diagram. The ointment carrier (D) is made of hard rubber 2¾ inches long over all, hollowed out into a cavity 1 inch in diameter and containing, roughly speaking, 1½ ounces of salve.

Instead of a plunger worked with the thumb like a syringe, which was the type of ointment carrier devised by the late Dr. Trenwith, the writer has used the screw form of plunger borrowed from the Allingham pile pipe. The purpose in making the ointment carrier as large as it is has been to permit it to be grasped firmly in the whole hand of the operator, thus preventing the very irregular movement of other types of sound, which as previously stated, irritates the deep urethra and prevents the use of any but a very thin ointment. A few turns of the screw may be gently given, after the tip of the sound is in the deep urethra, thus pressing out the required application. In order to reach the deep urethra the shaft of the sound must be held vertical. The shortness of the beak then provides that its tip is in the forepart of the deep urethra; a longer beak, such as the standard, would usually result in depositing the salve within the bladder, which is not a desirable thing to have occur.

In order to free the beak of the sound from the form of salve used so as to change to another salve, the writer adopts the following steps: After withdrawing the sound he thoroughly washes and scrubs the beak and immerses it for a few minutes in a 5 per cent. carbolic acid solution; he then squeezes out a small quantity of the salve and with a sterile piece of gauze wipes it away, then by reversing the screw the small quantity of salve in the beak of the instrument between the tip of the sound and the tip of the delivery tube is sucked into the delivery tube, thus leaving the beak of the sound empty; it may then be boiled, if desired, and transferred to another ointment receptacle with its delivery tube.

The writer is indebted to Messrs. George Tiemann & Co. of this city for assistance in perfecting this rather serviceable apparatus, and offers it to the medical profession as an aid in the treatment of chronic urethral lesions of purely desquamative and catarrhal types.

Medical Items.

Contagious Diseases, Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending May 23, 1908:

	Cases	Deaths
Tuberculosis Pulmonalis	420	201
Diphtheria	397	37
Measles	1555	33
Scarlet Fever	1053	40
Smallpox	—	—

A NEW DUTY OF THE MEDICAL PROFESSION: THE EDUCATION OF THE PUBLIC IN SCIENTIFIC MEDICINE.*

BY HERBERT L. BURRELL, M.D.,

BOSTON, MASS.

THE welcome that is extended to us this year by this great metropolis is peculiarly grateful, for Chicago is the home station of this national association. This great city should serve as an inspiration to us all, for it personifies the zest of the American spirit—vigor, enterprise, and stability of purpose. This city, during the year, has lost one of its most gifted citizens, one whose name was honored in all countries, an ex-president of the association. All honor to the memory of Nicholas Senn, surgeon, writer, investigator, publicist, a man who did pioneer work in surgery and who was always ready to promote the interests of the medical profession.

The coming together of men of mutual aims must always be a subject of public interest. What is the meaning of this gathering of medical men from the length and breadth of this great country?

First: That individually they may be better able to care for the sick. Second: That they may collectively be better fitted to prevent disease. Third: That they may know men and their ways and by social intercourse may live fuller and broader lives. This association is a great power for good or for evil. May its acts be guided by motives that are directed toward the health and prosperity of the people.

There are many subjects of which I should be glad to speak. Some of them have been considered by the association in previous years. Medical education, medical legislation; the desirability and the question of the advisability of the medical profession taking an active interest in practical politics; the establishment of a national bureau of health; the abuse of medical charity, and the work of the Council on Pharmacy and Chemistry; all are subjects of vital interest. To-day I invite your attention to what I believe is a relatively new duty of the medical profession, that of judiciously educating the public in the present position of medical knowledge and in the advances that are being made in scientific medicine.

Until recently medicine has observed a silence as to its position and accomplishments that has made it unique among its sister sciences. A veil of mystery has surrounded it. Born, as medicine was, of fear, nurtured by superstition, it went through the centuries in twilight until it grasped the torch of science, which is beginning to illuminate its way. For long years medicine was only a handmaiden to theology. Faith, that inestimable gift to man, was the guiding star of medicine. Faith in "simples," in fetiches, in amulets, in poisons, in all the forces of Nature and in all the dread legion of phantasms that may be formulated by the mind, all these at times have held sway in medicine. Theories, hypotheses and "fads" ingenious and often containing a grain of truth have in turn dominated medical practice.

The profession has properly been conservative, because the truth in reference to health and disease has not been known. When the vital processes are looked at in the abstract, they are so marvelous and still so far from being entirely understood that it is little wonder they are surrounded by an air of mystery. The family practitioner of our grandfathers' days was a man who was greatly respected. He was discreet and silent. When he entered the sick-room he held his counsel. He appreciated the fact that he was in the presence of a human being afflicted with disease. Frequently he realized that he did not know either the natural processes of health or the natural history of the disease that he was facing; therefore, he was silent. The satirists have always pictured the practitioner of medicine as a venerable old gentleman who discreetly nodded his head in acquiescence or disapproval, who said vague things, and who encouraged his patient and the household to hope for the best and to prepare for the worst. I believe it is generally accepted that our profession has been deemed one that has been filled with charity and love of man, but it has not been conspicuous for its scientific methods.

During my lifetime I have seen, as have many of you, the development of scientific medicine. But medicine to-day, although a science, is still in part an art. Yet the sum of scientific knowledge in medicine is already very large, and as a science medicine has changed from the position in which it haltingly progressed until now it is advancing steadily along many lines.

The art of the practitioner during the past few years has not progressed so rapidly as the science of medicine. Rightly, the attention of the profession has been directed to ascertaining the causes of disease; hence the natural history of disease and its diagnosis have in large measure occupied the attention of the profession. The lack of training in scientific methods led men to reach conclusions from insufficient data; and when these men found that they were mistaken they were frequently swept to the other extreme—that of failing to accept anything of value unless it could be absolutely proved.

Meantime the art of the practitioner has languished. Proprietary medicines and nostrums have been too frequently used by practitioners, feeling as they have that "they may help and the patient wants them." Fortunately, experimental pharmacology at last has come to give us the truth, for by

*President's address at the Fifty-ninth Annual Session of the American Medical Association, at Chicago, June 2-5, 1908. From advance proofs, through the courtesy of the Editor of the *Journal of the American Medical Association.*

its findings we now know what really follows when a drug is given.

At present I believe that physicians are too conventional in their methods of treating disease. They have not paid sufficient attention to the alleviation of the suffering that accompanies some of the incurable maladies. Hydrotherapy, massage, electrotherapy, and particularly psychotherapy, as measures of relief, are permitted to rest in the hands of empirical practitioners, who but slightly understand the forces with which they are dealing. Human beings cling hard and fast to hope. They, fortunately, will rarely accept defeat. They constantly hope when in distress that aid will come by some intervention, physical, psychic or divine. This insistent demand for relief must be remembered by practitioners, but they should also recognize, as Louis did, that there is a natural course of disease.

Progress in science is always haltingly made. In medicine, which is but applied biology, the movement now is steadily forward; for through chemistry, biology, and physics has come some knowledge that enables us to comprehend more clearly many of the vital phenomena of life. To-day we are in possession of certain irrefutable facts. It is unnecessary for me to catalogue to you the advances that have been made in medicine during this last generation; suffice it to say that it has caused a revolution. The application by Lord Lister of Pasteur's work in biology has made a new era in surgery. Chemistry and biology have made sanitation a science. Physics has enabled us to comprehend some of the vital processes. These contemporary sciences have illuminated medicine, but have medicine and surgery in themselves properly advanced? I think not. The field for advance is still open in clinical medicine and surgery. The human being, particularly when sick, has not been scientifically observed as thoroughly as he should. Valuable scientific facts may be obtained by the clinician in the outpatient department and wards of a hospital, or, for that matter, wherever he meets disease. The reason that more of these observations have not been made in hospitals is due primarily, I believe, to the lack of adequate training of men in scientific methods, but perhaps more largely to the general belief that scientific work in medicine must be done in a laboratory. It will be granted, I think, that in science the closer one can observe a problem the better. Should not the wards of a hospital be the real laboratories of medicine? To-day there is in the wards of hospitals a wealth of facts that is not recorded even when recognized. When the opportunities that are really within our grasp are utilized, then there will be still greater progress in medicine.

The three great professions, theology, law, and medicine, have ever been the custodians of the spiritual, the material, and the physical welfare of man. Medicine has been until recently in the background. The principle of theology has always been and always will be a matter of faith. The law has been a series of rules of action based on precedent and intended to secure equity and justice between human beings. Medicine, however, from being an art that ministered to the physical distress of man, has come into a broader field of activity. Intelligent men and women now recognize that faith is dependent in large measure on the physical condition of the individual. Our criminal classes, it is now known, are frequently physical degenerates. Moral obliquities are often caused by physical conditions. The material welfare of man is no longer in the hands of the law alone; for great epidemics, which destroy scores of people and invalid thousands, and which often paralyze the commerce of a part of the world, may to-day be controlled by a knowledge of contagious diseases.

The leech which served in the Crusades was a camp follower, a servant retainer. To-day the medical man who is responsible for the health of troops in the field has as high a responsibility in gaining success as the commander-in-chief of the army. The balance of power between the nations of the earth is maintained, in part at least, by the fitness of troops for service. This statement I make as applicable to every civilized nation. Its truth has been demonstrated in every modern war; never more strikingly than in the Spanish-American War.

A singular and unprecedented apathy, to be charitable, prevented the chairman of the Committee on Rules of the House of Representatives of the United States Congress from permitting the United States Army Reorganization Bill to come before that body. And this notwithstanding the fact that the bill was favored by the President of the United States, the Secretary of War, and the United States Senate, while a careful canvass demonstrated the fact that the bill was favored by a majority in the House of Representatives. But within a few weeks the chairman of the House has seen the truth and has allowed the bill to be passed and it has now received the signature of the President. We are at last in a position to meet, in part at least, the exigencies of a modern war.

No man, woman, or child in the civilized world can be so situated, in labor, in travel, in attending schools or churches, in fact in existing, without being a debtor to the knowledge that has come from scientific medicine. This new phase of development in our profession adds greatly to its responsibilities. We are no longer a group of men and women who only soothe the brows of the afflicted and alleviate human suffering. Intelligent physicians or surgeons to-day know the natural history of some of the diseases with which they come in contact. Science has placed in their hands knowledge with which to control these diseases. They are public servants and their duty demands that they protect the individual against the ravages of disease as well as alleviate or cure. We, as the medical profession, are now in possession of truths that can help our fellow man. Is it not our duty to tell our fellow man? For we are told that "the gospel must first be published to all nations" (Mark 13:10).

Education has been, and I sincerely trust always will be, the cornerstone of our civilization in this country. No permanent advance will ever be made unless the people are educated to the truth. Laws are never effective unless the people want them to be enforced. I cannot recall any great or permanent advance that has been made by force alone; and even when force has apparently succeeded, it usually leaves an unjust and more or less complex, unstable condition. Our Civil War blotted out a great evil, but it left a race problem that has not been satisfactorily settled. The "flare-back" of force usually defeats itself. I have an abiding faith in the public. I believe in it. When made to think, it reaches a wise solution of a problem. Observe—the key to safe public opinion is to make the public think. Unthinking people are less to be depended on than animals. If it is true, that the medical profession now has accepted facts that bear on the welfare of the people, is it not our duty to make them known? Judicious publicity is, I believe, a new duty of the medical profession to the laity. How can this be accomplished? There has already been established

a Board of Public Instruction in this association. This board, as well as all committees, should be answerable to the Board of Trustees; it should be representative and eminently judicial in character, and should have as advisors the experts in the profession.

In what medical subjects should the public be educated? It will be better to teach thoroughly a few important subjects than to attempt to cover too large a field. Let us not be blind to the fact that our scope of usefulness as physicians in dealing with the large disease problems depends in great measure on the cooperation of the public. We must have intelligent cooperation to make our work as effective as may be. Tuberculosis is still the most pertinent subject on which information should be given. The public should be informed that at present an early, thorough operation is the most certain way of curing cancer. The work already accomplished by the public in cooperation with physicians in controlling tuberculosis, ophthalmia neonatorum, and scarlet fever comes to everyone's mind. The work that has been done in controlling yellow fever in Louisiana by the public and the medical profession is a striking example of educating the people as to the facts concerning disease. The various infectious diseases are obviously ones concerning which the public should be informed. The people should be educated as to the necessity of pure air, pure water, and pure food; they should know the hygienic value of bathing. They should know that hospitals are provided not alone for the care of the sick poor but that knowledge of disease may be advanced. Take a familiar example in our social life: When it is recognized and brought home to the public that contagious diseases in children are to a degree unnecessary, that by proper sanitation and medical school inspection they may be in large measure prevented, then people will demand that their little ones in public schools shall be protected against disease, which often leaves them invalided and crippled for life. A child among the better classes to-day, until it begins to go to school, is usually free from contagious diseases, but the moment it enters a school it is subjected to dangers from infection which it rarely escapes. To be consistent in our present method of life we might as well expose our children deliberately, as they did in country districts in former times, when a child was sent to a neighbor's to get the measles, as it was a convenient time for him to be sick. The physical and intellectual development of our children is in the public mind, but the possibility of preventing them, by adequate precautions, from having infectious diseases is not appreciated. The sanitation of churches, places of amusement, vehicles of transportation, so intimately concern the public that the essentials of their proper care should be widely known. When the public is so informed, it will demand a reasonable degree of security from infection. But, it may be said, all the truth is not known regarding these subjects; true, and, therefore, we must be very sure that we tell only the truth.

Commercial houses within a few years have found that it pays to care for their employees. It is true that in some instances a spirit of altruism has led to this action, but practical experience has shown that a higher and a better type of work comes from employees who are intelligently cared for. In one commercial house in Boston a physician gives his professional services to the employees as he might to a hospital clinic. If any salesman falls below in his sales he is directed to appear before this physician. A careful examination usually reveals some adequate physical cause that accounts for the individual's lack of energy. Anemia, indigestion, constipation, incipient tuberculosis are recognized and treated, and the salesman is frequently restored to his full earning capacity. Intelligent merchants recognize that the better care that they take of their employees the better service will be rendered in return. Loyalty is a force the value of which cannot be overestimated, and it is secured and preserved by employers who are really interested in their employees.

The czar-like dictation of labor unions which arbitrarily limits the amount of work that a man or woman is permitted to do is a force that seems necessary to meet the greed of capital, which in the past often cast aside its employees like wornout garments when they were no longer useful. I hope that labor unions in the future will demand not that the number of hours and the productiveness of the individual shall be limited, but that capital and labor shall protect the individual against disease, in order that he may have the highest degree of productiveness. Throughout the world there are cooperative business establishments in which the interests of the employees are protected in a measure, but this protection is usually financial. If the employer and employee could recognize that the preservation of the working capacity of the employee is of even greater importance than a 10 per cent. dividend on a few hundred dollars saved, a great mutual gain would be secured. Business men should see to it that their employees are informed as to the proper methods of life; protection against disease by employers is not alone a duty on their part, but a real financial investment, as recognized in the work of the Welfare Department of the National Civic Federation. The medical profession must recognize that cooperation with business men in these public duties is a new duty of citizenship.

Who among the public should first be educated? Those who are leaders in the community; those who are in positions of responsibility—national, state, city, and town authorities, trustees of hospitals and schools—they should first be informed as to the facts concerning disease. Experience has shown that the lay public takes a keen interest in everything concerning medicine and its progress. The success of nostrum vendors has demonstrated their skill in appealing to the sentiment of the public. The Board of Public Instruction should always appeal to the reason of the people. Great discretion should be used in selecting the subjects in which the public should be educated. Experience would teach such a board what not to do. "Don't" should be the motto for this board when in doubt as to educating the public.

What are the means by which we may reach the public? Newspaper articles on selected subjects, giving facts concerning a given disease, but not the treatment of disease, should be furnished the press. These articles should be signed and published under the authority of the Board of Public Instruction. That these articles should be judiciously edited must be apparent to all. No statement issued by the Board of Public Instruction should fail to be the absolute truth. Irreparable damage to the medical profession and to the public might be done by unwisely exploiting mooted subjects. It would be unfortunate if this new duty of educating the public in medical matters were taken up indiscriminately by the members of the medical profession. It may well be appreciated that this new duty may be con-

sidered a legitimate means of advertising the individual. But self-seeking for the medical profession, or for any individual member of it, would be quickly recognized by the public. Discredit, then, would be brought on the profession and on the individual.

Another means of reaching the public might be by magazine articles. The facts concerning certain diseases might well be given to skilled lay-writers, who should be paid for their services. A lay-writer has the art of presenting a subject to the public in an attractive manner. For example, let the subject of animal experimentation be investigated by one of the magazine writers of this country. Open wide the sources of information to such a writer. Then let a series of articles be published in order that the public may know the truth as to the inestimable benefits that have come from animal experimentation, not to men alone but to animals as well. Reprints of such articles, pamphlets and circulars of information would be a powerful means of educating the public. Let circulars of information regarding the subject of animal experimentation and of vaccination be placed in the hands of every legislator in this country; in fact, in the hands of every citizen who is misinformed as to the truth. In the event of a great epidemic of yellow fever or cholera, let a pamphlet containing the facts concerning the spread of the disease be sent to every householder in the district. Every physician would be then obliged to know the facts. This leads me to call your attention to one of the obvious effects on the medical profession of educating the public. It is to be regretted, but it is true, that there are ignorant practitioners in our profession. If the public is informed as to the facts concerning an individual disease, a physician will be forced to inform himself as to the recent advances in that disease.

To my mind, one of the most important movements in the association is the establishment of county graduate schools in the various States. I can conceive of no better stimulus to this work than the adoption by the county schools of a plan by which one of its members shall inform the public, once a year, as to the facts concerning some selected disease.

The work of the Council on Medical Education is progressing. Dilapidated medical schools are disappearing. Why? Publicity. When the public recognizes that in order to become a well-educated physician certain requirements are absolutely essential, then, and not till then, shall we have true reform in medical education. I commend to your consideration the work of the Council on Medical Education. It is dealing with the tap root of the tree of the medical profession. Its reforms must not be too radical. There are still isolated areas in this great country that cannot support the best educated physician. But the American Medical Association at least can stand firmly for safe, sane, and sound practitioners. To my mind, one of the most important functions of the Council is that it has established a monitorship over medical schools. Let the Council give to the profession, and to the public if necessary, the facts concerning the various medical schools of this country; publicity will do the rest.

Free lectures to the public on selected medical subjects constitute one of the most useful methods of spreading information. These lectures should be given by men who are authorities in their subjects; and the experiment as it has been tried in various parts of the country, particularly in Chicago and at Harvard, has been a success. At Harvard during this last winter the lectures have been so popular that at times a hundred or more people have been turned away, being unable to gain admission. A wide range of subjects has been covered in these lectures. Many factors influenced the attendance: First, the subject selected; second, the individual who gave the lecture; and third, the condition of the weather. Sunday afternoon lectures were better attended than Saturday evening lectures. Inclement weather markedly diminished the attendance. The most conspicuous factor that influenced the attendance at the lectures was the cooperation of the press. For example, when a lecture was given on a subject of great public interest, then if the press devoted from a half column to three columns to noticing it, the stimulus to the attendance at succeeding lectures was marked. Personally I have had nothing to do with these lectures, but I believe that they can be made effective almost in proportion to the cooperation of the press.

The medical profession, and many of the public, are afraid of the press. Whether this position on the part of the public is justified or not need not be discussed. I have never had occasion to appeal to the press for assistance and cooperation in any public measure without receiving hearty, but at times, to my mind, indiscreet assistance. The position of the press, as I understand it, is that it is the judge as to what constitutes news. Newspapers will publish what they think the public wants to know, but not what we think the public ought to know. They assume, quite properly, the right of decision. The greatest power that we can have to diffuse information is the public press. Let us be frank with it, and I believe that it almost invariably will be honest with us. *Collier's Weekly* and the *Ladies' Home Journal* have been wonderful forces in diffusing the truth.

There yet remains, ladies and gentlemen, a means of educating the public which I believe will be the most potent of all. This rests in the hands of the family physician—the man who has the care of the household, who watches the growth of the children, who sees the father and mother bend under the strain of life, react and again assume their work, the counsellor of the family—he it is who can carry into the homes of this country the judicious truth concerning disease. Well-educated people have recognized that the wave of specialism which threatened to obliterate the family practitioner was dangerous for the welfare of the whole. The trouble is that we all consider ourselves, when ill, as peculiar examples of some disease, when, as a matter of fact, all we need is the counsel and advice of a sound-minded family practitioner who has known us and our families for many years. This does not in the least deny the great advantage of having the benefit of special knowledge in reference to a special subject.

There is a distinct reaction, I believe, against the obliteration of the family practitioner. The well-educated family practitioner now has a new duty. He it is who should be the instructor of the family. This is particularly true in relation to the subjects which in medicine cannot with propriety be taught the public in masses; these subjects may be taught most appropriately to the parents and, if need be, to the children by the physical counselor of the family.

A great duty rests on the practitioner of medicine to-day. He must not shirk it; he must rise to his new burden, accept it and bear it. The reward to the medical profession for taking this new burden of judicious publicity in medicine will be a broader

life for the practitioner, a greater consideration for his fellow man, better citizenship and the recognition by the world that the medical profession is a great public benefactor.

22 Newbury Street.

THE CANCER PROBLEM.*

By GEORGE W. CRILE, M.D.,

CLEVELAND, O.

A just presentation of the status of surgery in any subject is as difficult as the honor of presenting it here is high, for the forward movement in research and investigation in the whole field of medicine is world-wide and aggressive, and singularly effective. Events follow each other so swiftly that the profession itself requires an almost daily readjustment. Is there within the past generation in any other department of human endeavor a record of so many basic discoveries as in medicine? Who can read the triumphs of preventive medicine, of biochemistry, of physiology, of pathology, without pride?

Surgery has all but conquered the infections and benign tumors of the pelvic organs, of the kidney, of the appendix, and of the gall-bladder: it has mastered the complications of gastric ulcer, it has cured hernia, removed goiters, and corrected deformities. All these are, or may be, serious operations, and yet in the hands of the present-day masters the average immediate mortality is not more than 1 per cent. What were, or what would have been, the results of such operations a generation ago? Many of these operations were then unknown, while those known were performed with possibly twenty times the present mortality.

Surgery points with pride to its success in combating infections, benign tumors, obstructions, and deformities, but what can be said as to the progress in the treatment of certain malignant tumors, of cancer—a word used here to include all malignant new growths? It has been stated, and I believe truly, that the greatest outstanding obligation of medical science to mankind is the discovery of the cause of cancer, or at least of a cure for it. There is at present a universal movement in this direction. Governments and individuals have provided funds for laboratories and hospitals. Many of the greatest minds of to-day are engaged in an effort to solve this cancer mystery. The biologist, the chemist, the pathologist, the clinician, and the statistician are enlisted. All honor to the men who have the courage to risk a life's work in what may prove to be vain endeavor; but what a victory for him who first reaches the goal—the delivery of mankind from its most dreaded disease!

Although the cause of cancer still remains unknown, many of its phenomena have been carefully studied. Cancer occurs in every climate and among all mankind, savage and civilized; in wild and in domestic animals, the carniverous and the herbivous; in birds, fishes, and reptiles; and even in the lowly oyster. Throughout Nature the histologic picture of cancer of any definite type is the same.

The frequent assertion that cancer is on the increase, as shown by certain mortality tables, may be partly accounted for by the greater number of correct diagnoses, by the general increase in longevity, and by the decrease in infant mortality. Through the natural evolution of medicine one should expect a further fall in the death rate from infectious diseases, and hence a relative rise in the number of cancer and senile deaths. On the contrary, an increasing number of cases of cancer are cured surgically each year. This balancing of conditions will tend further to alter the percentage of cancer incidence. Bashford and Murray have shown that absolute statistics of cancer prevalence is not at this time available. If the rate of cancer prevalence estimated for the British Isles be adopted as accurate for this country, it may be estimated that there are in the United States at this moment approximately 80,000 cases of cancer, and possibly a million cases among the entire population of the world. According to statistics, one woman in eight who reaches her thirty-fifth year dies of cancer. The post-mortem statistics of hospitals show that cancer is found in one in twelve autopsies.

Cancer not only destroys countless lives, but it destroys them by a method of merciless torture. To die from an accident or from an acute infection is a matter of days or weeks; to die from cancer is a matter of months or years, and this is a period not alone of suffering, but of suffering without hope—a horrible species of cellular cannibalism.

The biological characteristic of the cancer cell is its power of limitless division. A single strain, for instance, the Jensen mouse tumor, has been transplanted thousands of times during a period much longer than the natural life of a mouse. In that period a large quantity of tumor tissue is grown, apparently capable of endless cellular division, and showing no evidence of decreasing activity. It seems probable that cancer cells may multiply indefinitely and may, possibly, like the ameba, prove to be immortal.

But few spontaneous cancers have been successfully transplanted from one individual to another of the same species, and no cancer has as yet been transplanted from one species to an individual of another species. Few, if any, cases of cancer transplantation have occurred between human beings. A surgeon's immunity from cancer infection during operations is apparently complete. Gaylord and Clowes have shown that in the transplanted cancer of the mouse an immunity may be established in the recipient. This immunity is produced by the growth of the transplanted tumor, and is made obvious by its complete regression and the impossibility of again successfully planting such a tumor in the same animal. Natural immunity to cancer has been found in some animals. Ewing and Beebe have observed similar immunity in a strain of transplantable sarcoma of dogs.

Although the primary cause of cancer is not known, many of the predisposing causes and precancer states are known and can be recognized. In sarcoma of bone there is a history of trauma, usually severe, in not less than one in three cases. The growth of carcinoma rarely follows a single traumatism, but in the visible fields it is frequently preceded by chronic irritations, by scars and ulcers, by hyperplasias, by chronic inflammation, and by preexisting benign growths. Examples are smoker's cancer of the lip, mouth, and tongue; cancer resulting from friction of clothing; from the picking of warts and moles; from the irritation of nails in the mouths of lathers; from the irritation of a broken tooth or tooth plate; from the soot irritation of the chimney sweep; from fissures and cuts of the lip; from senile warts or scales of the face; and from irritation of foreign bodies, such as calculi in the gall-bladder, the kidney, and the urinary bladder.

*Address on Surgery at the Fifty-ninth Annual Session of the American Medical Association, June 2-5, 1908. From advance sheets through the courtesy of the Editor of the *Journal of the American Medical Association.*

There is, in fact, scarcely an instance of a complete account of a case of visible cancer that does not give a clear precancer history—a history of chronic irritation, ulcer, scar, hyperplasia, innocent tumor, or a combination of these factors.

Cancer notably follows fixed laws. Is the inception and growth of cancer of the face, lip, or tongue different from the inception and growth of cancer of the stomach? Were the stomach as exposed to view as is the lip and tongue, is it not probable that just as well defined precancer stages would be observed? Or, were the lip and tongue hidden, as is the stomach, what should we know of the inception phenomena of cancer of the lip or tongue?

Among the benign growths predisposing to cancer, let us note fibromata, papillomata, adenomata, and cysts; such as papillomata of the larynx and bladder, adenomata of the uterus, breast, and intestine; cysts of the ovary and breast; and the hypertrophy of the thyroid.

Among the benign tumors of the uterus, one in thirty becomes sarcomatous; and in one in fifty cases the uterus becomes carcinomatous. Most innocent tumors of the parotid gland ultimately become sarcomata. Many irritated moles freely metatasize as deadly melanomata. Warren, Cathcart, and others have pointed out the frequency of the transformation of benign and malignant tumors. Indeed, as Bland-Sutton has well said: "The more carefully the histology of tumors is investigated, the more obvious does it become that the borderland between innocent and malignant species becomes less easily definable."

We may conclude, then, that chronic irritations, ulcers, and benign tumors are potential cancers, and should be considered in that light. The precancer stage is the prophylactic stage.

While the treatment of precancer states and benign tumors is effective, easy, and safe, the treatment of developed cancer is to-day perhaps the most difficult problem of surgery. Has there been progress? Has the limit of operative measures been reached? Inasmuch as excision is still the only reliable means of cure, what has excision accomplished?

Twenty-one years ago Butlin collected statistics of 364 operations for cancer of the larynx, esophagus, kidney, thyroid, and pylorus. Two-thirds of the patients died of the operation, and of the 126 survivors only one was known to be alive and free from the disease three years later. Butlin characterizes this result as ghastly. Halsted quotes the elder Gross—and Gross was the first surgeon of his day—as stating that he had never cured a case of cancer of the breast. Halsted, however, developed this field by applying a perfected technique to a correct pathological conception, and his work serves as a general model for cancer operations.

In the Johns Hopkins clinic 47 per cent. of all cases of breast cancer operated on have remained well for three years or more. Considering only the cases that seemed at the time of operation to be clinically favorable, seventy-five out of every hundred were cured. A group of cases still more impressive is that consisting of those in which a clinical diagnosis of cancer could not be made prior to operation. Of these, 96 per cent. remained well for three years or more. The operative mortality in the representative clinics to-day is less than 1 per cent.

In cancer of the head and neck there has been a similar evolution, resulting in an improvement so extraordinary that to-day the mortality rate of the major operations in this field is no greater than that of tracheotomy or herniotomy a generation ago.

Little or no improvement is seen in the results in cancer of the esophagus or of the thyroid. Neither has there been any progress noted in the purely surgical treatment of round-cell sarcomata, especially of the bones and lymphatic glands.

The surgical possibilities in some of the well-developed cancer fields may be best displayed by arbitrarily dividing the cases into three clinical groups; those favorable to operation, those unfavorable, and those suitable for palliative operation.

In the favorable group are included all cases that prior to operation gave no evidence of the involvement of any other tissue than that originally attacked; for example, in cancer of the breast, those cases in which no glands are palpable and the growth has not sensibly involved the skin, the muscles, or other structures.

In the unfavorable group are included the cases presenting demonstrable extension beyond the tissue of primary lesion. Among these there are relatively few cures.

In the group of cases suitable for palliative operations are included those on which operations, such as gastroenterostomy, colostomy, and visceral anastomosis for extensive visceral cancer are performed without hope of cure, but to relieve symptoms.

When operated on according to the highest standards of the present day, the favorable group of cancer cases of the skin, lip, tongue, breast, larynx, and certain viscera show a three-year cure in approximately eighty out of every hundred cases. When the disease, even in the favorable group, is so situated, for example, in the tonsil or esophagus, that the surgeon is hampered in the application of the principles governing operations for malignant disease, the probability of cure is greatly reduced.

From the aggregate results of operative treatment, then, it may be concluded that great progress has been made. Why? Because certain fundamental principles have governed the technique. These principles are block excision of the entire cancer field, including the area of lymphatic distribution and drainage, and extreme care in handling the cancer tissue to prevent the spread of cancer cells beyond the operative field. The knife must never touch cancer tissue. Rough surgery constantly defeats itself. Pathological thoroughness and gentleness, added to a perfected surgical technique, have been rewarded by so many cures that first the profession and then the public gained confidence in the surgical treatment of cancer. Hence, patients applied earlier and better results followed, thereby increasing public confidence—a species of beneficent circle constantly leading to still earlier, hence more effective, operations. It is axiomatic to state that the earlier the operation the more certain is the cure. The chance of failure, as Andrews has emphasized, rises in geometric ratio with the lapse of time from the onset of the disease.

Has the limit of operative measures been reached? An answer to this question demands that the obstacles in the way of better results first be known. Many, perhaps the majority, of cancer patients are seen too late. Why? When the growth is in a visible field the patient may not suspect the changes in a wart, a mole, an ulcer, or a scar; or suspecting, even knowing the truth, he may not believe in the efficacy of an early operation. Education is here needed. The family physician may delay because he wishes to be sure of the diagnosis; he may wish to try local treatment, or a course of

specific treatment, whereby, he argues, he is giving the patient a chance; but, as Butlin has remarked, the physician has thus too often robbed the patient of his only chance and has allowed the cancer to gain a mortal grip. Again, some physicians question the diagnosis until there appears glandular enlargement, general emaciation, and cachexia. I have often thought that, pending a more general enlightenment, it would be a great boon to mankind if the words "glandular enlargement and cachexia" as denoting symptoms of cancer were stricken from every textbook of medicine. These are terminal symptoms, and indicate that the surgical opportunity is forever lost. Were the result not so tragic, such professional simple-mindedness would be ludicrous. Finally, some physicians make a diagnosis, but yield to their natural inertia and drift with the disease. Such men need an awakened conscience. While the early and hence curable stage is easily recognized in the external field, what possibility is there by our present inadequate means of diagnosis of recognizing internal cancer in its curable stage? It is in these cases of internal cancer that advanced disease only is recognized, and in these that surgery appears at its worst. All clinicians acknowledge the inadequacy of present methods of diagnosis of concealed cancer. Ewald has well said: "Exploratory incision in suspected cases is all well enough, but one cannot expect the whole community of possible suspects to submit to being opened for inspection in order that the occasional case may receive early operation."

By analogy and from actual experience we believe that operations for incipient cancer of the stomach and intestines yield as good results as operations at a like stage for external cancer. Is there in internal cancers a warning precancer stage? Boas, Ewald, Hauser, Rosenheim, Lebert, and many others recognize the fact that simple ulcer may become transformed into cancer, and they estimate the frequency of such transformation as 5 per cent. or more. Of cancers of the stomach, Mayo, Moynihan, Rodman, and others find in over 50 per cent. a history of previous ulcer. Ewald has recently declared that such cancerous transformation is far more frequent than has hitherto been assumed.

The study of the living pathology at the operating table is daily convincing surgeons that gastric cancer, like cancer of the skin, tongue, the mouth, and the lip, has frequently a precancer stage, and that stage is usually ulcer. Ulcer, then, may have a sinister meaning. As Park has emphasized, cancer itself has no symptomatology. Kelling has interestingly opened the problem for a biological test for cancer. Basing my inferences on the work by Beebe, Clowes, and others, on the chemistry of cancer, and on the general work on hemolysis by many men in recent years, I was able to interpret the hemolysis in one of my early cases of direct transfusion of blood in a hopeless cancer case. Wile and Beebe have found hemolysins in transplantable sarcoma of dogs. My clinical case suggested the investigation of the hemolytic property of cancer blood as a possible aid to the diagnosis of cancer.

I am indebted to Dr. Beebe and Dr. Macleod for many suggestions. An assistant trained in this work has tested for me all available cancer material during the past eight months. The technique is exacting, requiring close attention, and unless precisely executed will not justify practical interpretation.

The reaction is the following: The blood serum of a cancer patient may hemolyze normal corpuscles, but normal blood serum usually does not hemolyze the red corpuscles of a cancer patient. In some patients—thus far only those with inoperable cancer—there was reverse hemolysis. The cancer corpuscles were hemolyzed by normal serum. In some cases there was no reaction. If this reaction is to be of diagnostic value, then it must occur in cancer cases only or in diseases not readily confused with cancer.

In one hundred and twenty-five normal individuals tested there was hemolysis in no instance. Among 80 patients with cancer, 82 per cent. showed hemolysis, while those with benign tumors showed no reaction. In the cases of tuberculosis those showing hemolysis showed a much greater autolysis than hemolysis, thus giving a characteristic reaction. In chronic suppurations and acute infections no hemolysis occurred.

Hemolytic tests of the extracts of cancers and benign tumors were also made. We were able to corroborate Beebe's observations that the extract from cancer tissue caused active hemolysis, while the extract from benign tumors showed no hemolysis. This suggests the origin of hemolysins in the blood of cancer cases. No hemolysis, then, has been observed in normal individuals, none in the victims of benign tumors, and none in those of pyogenic infections. Hemolysis occurred in 82 per cent. of cancer cases and in a considerable percentage of tuberculous cases, which, however, can be differentiated by the autolytic reaction.

Of the 20 per cent. of cancer cases that did not show hemolysis, all but one were either inoperable or very advanced. There was but one negative reaction in the early cases. In cases of suspected cancer giving negative tests the chances have been twenty to one that the cases were either in a late stage or nonmalignant. Cured cases showed no hemolysis.

In a myxoma of the breast of long duration, which had recently enlarged, the clinical diagnosis was "cancer transformation." Hemolysis was negative. The case proved benign.

A bone tumor gradually enlarging during six months was clinically diagnosed as sarcoma; hemolysis was negative; osteomyelitis was demonstrated. A similar result was observed in a case of tumor of the clavicle. A solitary tumor in a large breast of a woman of 46 was clinically diagnosed carcinoma; hemolysis was negative. The tumor proved to be a small cyst surrounded by hyperplasia.

A case of secondary anemia with a history of indigestion without symptoms of cancer showed hemolytis; two months later a tumor of the epigastrium became palpable and a fragment in the vomitus showed carcinoma.

A case of luetic stricture of the sigmoid under treatment for ten years showed hemolysis. The patient was operated on and an early stage of "cancer transformation" was found.

In a uterine fibroid without suspicion of malignancy a routine hemolysis test was made. Hemolysis occurred and at operation sarcomatous transformation in the center of the tumor was disclosed.

Although in its present state of development the hemolytic test for malignancy is not specific, the reaction may be a valuable aid in diagnosis, and has more than once been the only positive evidence. The entire subject is a promising field for investigation. The limit of resources in making an early diagnosis, hence, an early operation, even in internal cancer, has, therefore, by no means been reached. It has frequently been stated that the limit of operative possibilities has been attained. Have the minimum of operative mortality and the maximum of

safe incision been reached? The principal operative risk may be expressed as the sum total of shock, hemorrhage, and infection. Even if it is assumed that operators cannot be more gentle, more precise, and more dextrous, thereby still further minimizing shock and hemorrhage, newer methods of avoiding and of treating these complications are at hand.

In cases in which the blood of a cancer patient has not been so altered as to render the mixing of normal blood with it unsafe, hemorrhage and shock may be successfully controlled by the direct transfusion of blood. Cancer patients rendered poor surgical risks by hemorrhage may, by the means of direct transfusion of blood, become good risks and safely undergo operation. In like manner, a dangerous degree of shock following operation may be relieved almost with certainty by transfusion. The direct transfusion of blood, when properly employed, has proved almost a specific treatment for both shock and hemorrhage. Neither shock nor hemorrhage can cause death except by anemia. There cannot be a fatal anemia if a sufficient amount of blood is in the circulation. The only exceptions to this statement are cases of certain organic lesions. Cancer patients reduced by hemorrhage, or otherwise, may be operated on with safety by uniting the vascular systems of the donor and the patient just prior to the administration of anesthesia. Enough blood is transferred from the donor to the patient to give sufficient stability to the latter's circulation and to warrant etherization. An assistant is detailed to take charge of the transfusion, regulating the flow at the discretion of the surgeon. If the patient's blood pressure falls during the operation, or if his pulse quickens, sufficient blood is transferred to regain a stable circulation. At the completion of the operation the patient's circulation is usually greatly improved over its condition at the beginning.

In every case of cancer it is necessary to make preliminary hemolytic tests. If the patient's serum hemolyzes the proposed donor's corpuscles but little harm will be done. The serum of the donor's blood will in itself answer the purpose of filling the patient's relaxed vessels. Should there be a reverse hemolysis, that is, should the donor's serum hemolyze the patient's corpuscles, then a transfusion is strictly contraindicated, but the cases of reverse hemolysis thus far observed have been inoperable.

The following is illustrative: A case of papilloma of the bladder which had degenerated into carcinoma had been reduced by long-continued and progressive hemorrhage to the following condition: Hemoglobin 25, red count 1,900,000, blood pressure 110, pulse rate 132. The patient was clearly unable to withstand a resection of a large portion of the bladder, together with excision of a large tumor, but an operation was performed as above outlined, with the patient's son as donor. About one-fourth of the bladder was excised and an extensive plastic operation on the ureter was made. At the end of the operation the patient's shrunken, anemic face was full and pink, and his circulation was markedly better than before the operation. He made a splendid recovery. Other cases have been equally successful.

In the prevention and control of infections, especially in operations on the head and neck, much more may be accomplished. The mediastinum may be protected by developing a preliminary granulation barrier, which is done by making a preliminary dissection into the deep planes of the neck and packing with iodoform gauze five days prior to the operation; blood inhalation may be prevented and anesthesia simplified by nasopharyngeal tubage and packing. Better protection of patients from chilling, the employment of skilled anesthetists, and other similar means are constantly decreasing the number of infections and pneumonias. In my last 72 major operations in this field there was but one fatality.

The *x*-ray and radium have a curative effect on certain superficial cancers. In doubtful cases the skin flaps after operation may be retracted and the *x*-rays applied directly. In this manner the deep field, and therefore the cancer cells, may become superficial, and hence amenable to the *x*-ray influence. A number of cases of sarcoma have been cured with Coley's toxins. According to Coley, the postoperative use of mixed toxins is an aid.

Truly, the attainment of the limits of surgical possibilities is still far removed; the operative sphere may be still further extended, and surgical risks may be further diminished. Although surgery has accomplished much and holds out bright hope of accomplishing more, is there not evidence that other methods also may cure cancer? The work of Gaylord and Clowes, Beebe and Ewing, Ehrlich, Loeb, and others, demonstrating a not infrequent immunity against cancer, was utilized by Beebe and myself in an attempt to cure transplantable sarcoma in dogs by maximum bleeding of the "tumor dog" and heavy overtransfusion from an immune dog. By this method we have cured of sarcoma nine out of eleven dogs, some of which were cachectic and had metastases. The cured animals in turn became immune and were successfully employed for curing and immunizing other dogs. These animals since have been repeatedly inoculated with sarcoma, but have remained not only well but immune for more than a year.

Arguing from this work and from the fact that among the lower animals certain ones are naturally immune, we have transfused normal blood into six human subjects having sarcoma, their tumors having been removed previous to transfusion. Sixteen months have now elapsed since the first case was so treated. Although the cases were of the round-cell and spindle-cell types, presenting an exceedingly bad prognosis if excision alone were done, and although they are at this time apparently free from the disease and show no hemolysis, they will be available, as arguments on which to form a final judgment, only after three or more years. Should these patients be cured and become immune, it is likely that they may be available for curing others, so that eventually a group of immunes may be established. The whole matter of immunizing against sarcoma is at this time wholly experimental, and my statements are presented with that understanding.

SUMMARY AND CONCLUSION.

Cancer is widely distributed in Nature; is slightly, if at all, communicable; is not yet proved to be increasing or hereditary; and is rarely transplantable. Its biological characteristic is the power of endless division of its cells. The natural prognosis is death. Frequently there are well-defined predisposing causes and precancer states. The precancer stage is the preventable or curable stage. It is vastly better to prevent a cancer than to cure it. No specific therapeutic measure exists; the knife is still the most reliable means of treatment. In its beginning cancer is always local and is curable by complete excision. The chances of cure diminish in inverse geometric ratio to the lapse of time since its inception. There is evidence that a reliable blood test for cancer may be established; and there is a

possibility of utilizing for cure the immunity principle through transfusion of blood.

If there is in many cases a recognizable and curable precancer stage, if the disease in its incipiency is local and curable by excision, if the magnitude of the necessary operation increases in a direct geometric ratio and the chance for cure diminishes in a reverse geometric ratio with the lapse of time since inception, what is the duty of the profession, especially in its organized function and in its altruistic aim, toward the hundreds of thousands of fellow creatures who now, without suspicion of the dreadful truth, are in the precancer or early curable stage of cancer? What is the duty of the profession toward hundreds of thousands who will be stricken next year and each year to follow? This duty is to undertake a campaign of cancer education. The public is entitled to receive from the profession all the enlightenment required for self-preservation. It may be difficult to persuade a man to change his political tenet or his religious creed. Sentiment here may bind him closely. There is no tie of sentiment between a man and his cancer. Enlightenment ought to be easy and effective.

Finally, a careful consideration of the progress made in cancer research and in treatment should banish despair, give new hope, and urge all to put forth still greater endeavor to conquer in the end.

COMMENTS UPON AN UNUSUAL CASE REQUIRING CESAREAN SECTION.*

By WALTER T. DANNREUTHER, M.D.,

NEW YORK SITY.

ASSISTANT SURGEON, ST. BARTHOLOMEWS CLINIC; ASSISTANT GYNECOLOGIST, WEST SIDE GERMAN DISPENSARY.

Cesarean section is an operation frequently resorted to to-day. Considering our present aseptic methods and modern technique, our textbooks tell us that our case records should show no mortality as a result of the operation. This, unfortunately, is not true, although, except for instances in which the operation is performed to obtain a living child from a dying mother, it should be. There are six prerequisites absolutely essential to the ultimate success of cesarean section; and by success, I mean a living mother and child. Firstly, and most important, a surgeon who possesses at least as much common sense and good judgment as manual dexterity and operative skill; secondly, a sufficient number of well-trained assistants who understand what is required of them, and do it accurately and unhesitatingly; thirdly, an expert anesthetist; fourthly, a perfectly aseptic technique; fifthly, the best possibly attainable condition of the mother; and sixthly, a viable child, *in utero*, in the ninth month of its development, before the onset of labor. "The time, the place, and the girl," are indeed important factors. The following case presents some features of unusual interest.

L. St. C., age eighteen, single, a member of a troupe of "midgets," was admitted by me, as House Surgeon, to the Gynecological service of Dr. J. J. Mooney, in the Jersey City Hospital, March 15.

Family History.—Negative. Father and mother were large-boned, well-nourished, and well-developed individuals. Patient does not know whether they are living or not. She has two sisters and a brother, all living, also of normal size and development. No tuberculosis, syphilis, malignancy, rheumatism, or deformities in the family.

*Read before the Tri-Professional Medical Society, New York City, March 17, 1908.

The woman had rickets when six months old. Otherwise her general health has always been excellent. Menstruation occurred at the age of thirteen, and has always been regular as to time of occurrence, duration, and amount; she never had any dysmenorrhea. Last menstruation on the 26th of the preceding May. Breast changes, morning nausea, etc., appeared during the first three months following. Patient now presents all the symptoms of pregnancy. Date of labor calculated to be April 2.

Physical Examination.—The patient is well nourished, and apparently in excellent general health; somewhat excited by the examination. Height three feet eight inches. Has no perceptible enlargement of the thyroid gland, and no pressure symptoms. Abdomen measures three feet six inches in circumference. No cardiac murmurs. Lungs clear. The diaphyses of the long bones are underdeveloped, while the epiphyses seem almost normal in size. There is no kyphosis or other deformity of the spinal column. The fundus uteri extends almost to the ensiform cartilage. Fetal heart sounds are audible just below and to the left of the umbilicus. The vaginal orifice and cervix appear to be normal.

Fig. 1.—Before operation.

Pelvic Measurements.—Interspinous, 17cm. (7 inches); intercristal, 20.5 cm. (8½ inches); external anteroposterior, 14.5 cm. (5½ inches); right external oblique, 17 cm. (6¾ inches); left external oblique, 17 cm. (6½ inches); internal conjugate, 3 cm. (1¼ inches); internal anteroposterior, 4 cm. (1½ inches).

Operation.—March 31, by Drs. Mooney and Dannreuther. Anesthesia by Dr. M. E. Flaherty, of the House Staff. All aseptic and antiseptic precautions observed. Incision through the abdominal wall in the linea alba, extending from 1½ inches below the ensiform cartilage to the symphysis pubis. Second incision through the uterus, *in situ*, in the middle third of the median line. Time, 13 sec-

onds. No attempt was made to control the bleeding from the abdominal wound, which was inconsiderable. The child was quickly seized, the cord being clamped and cut, and was taken to another room by Dr. C. A. Plume, Assistant House Surgeon. Artificial respiration was unnecessary, as

Fig. 2.—Before operation.

the child cried lustily immediately after extraction. The child delivered, a nurse began pouring a continuous stream of normal saline solution, at a temperature of 120° F., directly upon the uterus. This promoted rhythmical contractions, facilitating the removal of the secundines, and controlling hemorrhage. Three layers of continuous catgut sutures were introduced into the uterine wound: two into the musculature, and one into the peritoneum. One operator completed the first suture while the other began the second, etc. This procedure is a valuable time saver. No attempt was made to sponge out the abdomen, the saline solution being purposely allowed to remain. The abdominal wound was closed by a continuous through-and-through chromic catgut suture, reinforced by silkworm-gut interrupted skin sutures. Time, from the first incision to the late suture, 13 minutes.

The anesthetic used was chloroform, followed by ether, which the patient took well. The pulse did not rise above 88, and was of good quality throughout.

Post-operative History.—The baby was well nourished and developed in all respects. Weight, seven and one-half pounds. Mother rallied well after operation. Recovery was uneventful, the abdominal wound healing by first intention. Sutures were removed on the tenth day. The cervical canal being well open, dilatation for drainage was unnecessary. Lochia normal. The mother secreted but a minimum quantity of milk, so the baby had to be fed artificially. Both were discharged from the hospital in excellent condition four weeks after the operation.

Unfortunately, we do not always see the woman requiring cesarean section early enough to operate under the most favorable circumstances. But I am fully convinced that most of the cases comprising the admittedly small mortality that some obstetricians' case records show, are due to errors in judgment on their part. In an instance where the indication for this operation is absolute, as it is with an internal conjugate diameter of 7 cm., or less, or where there is equivalent disproportion between the fetal head and pelvic space, and the patient is seen early enough to allow of satisfactory arrangements for operation being made, before the onset of labor, death of the mother as a result is inexcusable. The chances for the child should be as good as, or better than, in spontaneous births. It is not subjected to the slightest traumatism, such as version, forceps application, etc., nor any of the possible accidents, as in a delivery *per vias naturales*. In lesser degrees of obstruction, whether due to dystocia, tumors, or other pathological conditions, the indication for cesarean section is relative. That is, it may be selected in preference to symphyseotomy, pubiotomy, difficult version, difficult forceps applications, induced premature labor, and embryotomy. Whitridge Williams believes that it would be better to advance the absolute indication to 7.5 cm. in simple flat pelves, and to 9 cm. in generally contracted pelves. Personally, provided we have a living child, I should prefer cesarean section to any of the above procedures. In symphyseotomy and pubiotomy, there is special susceptibility to infection, and the remote results are uncertain and unsatisfactory. The other manipulations endanger the life of the child, with the exception of embryotomy, which means its death. In the case here reported, the indication for cesarean section was absolute, the mother in good condition, and the operation performed three days previous to the cal-

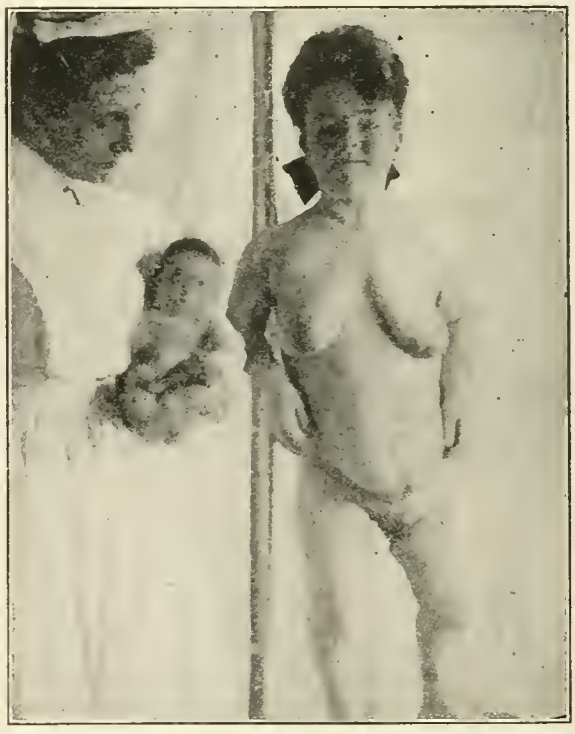

Fig. 3.—Twenty-one days after operation

culated date of labor. The practice of waiting for the inception of labor pains cannot be too strongly condemned. True, the uterus is awakened to active rhythmic contractions, the cervix is more patulous, and will perhaps permit the delivery of the placenta by the natural route. But the uterus re-

tracts equally as well in operation as in labor, especially if stimulated by a hot irrigation, and the drainage is sufficient, or can be made so. I can see no advantage in allowing the placenta to remain. Besides, after labor has begun, we are running the risk of the mother becoming exhausted. Operation a few days before labor permits better preparation, the patient is not in any danger of becoming exhausted, and it is certainly to our advantage to operate before rupture of the membranes, as there is less traumatism and extraction is easier. I should ascribe the majority of maternal deaths to imperfect pelvimetry, ignorance of the necessity for operation, infection carried by dirty fingers or instrumentation, attempts at other methods of delivery, and other varieties of obstetrical tinkering.

This patient must have presented a very rare and exaggerated type of rachitis in infancy. There are many things peculiar about the resulting deformities. What an enormous amount of reabsorption must have occurred in the diaphyses of the long bones. And why should the flat bones of the pelvis be subjected to such extreme distortion, while those of the cranium are not abnormal in any respect? We also would expect to find some deformity in the bony walls of the chest, especially those known as funnel-breast and pigeon-breast, or a kyphosis of the spinal column. In Fig. 2 it will be noticed that there is a slight apparent lumbar lordosis, but this was compensatory for the abdominal enlargement rather than for a kyphosis higher up, and was not evident after operation. Such an individual affords a layman amusement, but the true physician feels only pity and compassion for her misfortune. Incidentally, I might mention that this was the bravest and best patient that I have ever had.

I believe in performing cesarean section as rapidly as possible, without endangering life. But I do not believe in foolhardy operating for the sake of saving time or establishing a record. Have the instruments laid out in the order in which they are to be used, and have them handled by a competent nurse. Always make two incisions: one through the abdominal wall, and one through the uterus. Uterine incisions other than the median longitudinal, such as the Cohenstein, Kehrer, Fritsch, etc., in my estimation do not possess the supposed advantages claimed by their originators. In most cases it may be taken for granted that there is no loop of intestine between the uterus and parietal peritoneum. Nevertheless, I have seen one of the best gynecological surgeons in New York completely sever the intestine trying to save a few seconds by making but one incision. The slight hemorrhage from the abdominal wound requires no controlling. Pay particular attention to the peritoneum, by *leaving it alone*. For this reason, I believe it is better to allow the uterus to remain *in situ* than to deliver it outside the abdomen, which also predisposes to hernia and adhesions. The incision being so large, there is plenty of space to work entirely within the abdomen. Most operators adjust a loop of a constrictor around the cervix to control the uterine hemorrhage. This wastes time, and is unnecessary if a hot irrigation is used, as described above. Should the hemorrhage be profuse in spite of this measure, manual compression will easily control it. The constrictor also may cause fetal asphyxiation, and has a tendency to produce partial uterine paralysis. The irrigation serves two purposes, besides promoting retraction: It washes out most of the liquor amnii, and being absorbed by the peritoneum, acts as a stimulant. It should be poured in a continuous stream, directly upon the fundus, from the time the child is extracted until the uterus is closed by sutures. Have two clamps and a pair of scissors ready for the umbilical cord. The child and secundines should be delivered as rapidly as possible, and the baby taken in charge by a physician, prepared to administer artificial respiration. The method of closure of the uterine and abdominal wounds should be that which seems best in the judgment of the operator. Unless particularly indicated, buried sutures are unnecessary.

The post-operative treatment should be that following any other laparotomy.

The child in the case here reported being illegitimate, and the mother healthy and capable of bearing more children, there was no reason for doing the Porro operation. I see no reason why a second successful cesarean section should not be performed on this patient in a like manner. A concomitant hysterectomy or extirpation of the ovaries and tubes should not be done unless warranted by circumstances.

2030 Broadway.

A REPORT OF THREE CASES OPERATED UPON FOR LARGE ABDOMINAL TUMORS.*

By W. P. HARBIN, A.B., M.D.,

ROME, GEORGIA.

EX-A. A. SURGEON, U. S. A., EX-VICE PRESIDENT OF TRI STATE MEDICAL ASSOCIATION OF ALABAMA, GEORGIA, AND TENNESSEE.

Case I.—Nora, colored, was operated upon on November 16, 1906, for a large ovarian cyst. She is twenty-nine years old, and had all the diseases of childhood. She gave birth to a full-term child when she was fifteen years old. She had no illness of importance until five years ago, when she noticed a swelling in the lower part of the abdomen, on the left side, which increased in size very rapidly. On the morning of October 15, 1906, she rode eleven miles in a buggy, from her home to Rome, and I saw her for the first time in the afternoon of the same day. She was then able to be up and walk around, but with great difficulty. She had the typical facies ovariana and was extremely emaciated. Her face and body were covered with psoriasis; the skin at this time was covered with the scales characteristic of this disease, and the skin of the abdomen was especially thick with these scales. The peritoneal cavity was enormously distended, and presented a more or less spherical appearance. Consequently the ribs were spreading out to a marked degree, owing to the pressure from the tumor. The breathing was difficult and fast. She was unable to lie down in any comfort, on account of dyspnea. For several years she suffered greatly, especially at her menstruation. Her pulse varied from 120 to 130. The temperature, lungs, and heart were normal. The urine was free from sugar and albumin. There was no unusual difficulty in emptying the bladder or moving the bowels. There was a considerable amount of edema in the lower limbs and vulva.

The night before operation one-half ounce of Epsom salts was given. Several hours previous to operation the nurse scrubbed the abdomen with tincture of green soap and hot water. While the anesthetic was being given the abdomen was

*Read at a meeting of the Seventh Congressional District (Georgia) Medical Society, March 11, 1908.

scrubbed again in the same way, and afterwards disinfected with bichloride of mercury solution.

An incision six inches long was made between the symphysis pubis and the umbilicus. The cyst was evacuated, after which the adhesions to the abdominal wall and viscera were separated: some

Fig. 1.—Ovarian cyst. Case I

of these adhesions were dense and extensive. After freeing the sack, it was delivered through the incision in the abdominal wall. The pedicle was tied with fine silk, and severed external to the ligatures. The wound was closed with interrupted silkworm-gut sutures. Shortly after coming out from under the anesthetic, she sat up on the side of the bed, while the nurse was out of the room. She said she felt faint while sitting up, and lay down again.

There was no difficulty experienced in taking the ether, and she was under the anesthetic about one hour and twenty minutes. The day after the operation the maximum temperature was 101° F. After this there was practically no rise of temperature. The pulse varied for several days from 120 to 130. She slept seven hours the night after operation, without an opiate. No medicine was given afterwards except magnesium sulphate. The cyst wall, with its contents, weighed eighty-five pounds. The woman, after operation, probably did not weigh more than eighty or eighty-five pounds. On February 24, 1908, I saw her and weighed her. At this time she weighed 153 pounds, and said she was perfectly well.

Case II.—Jennie, colored, was operated upon in November, 1906, for a large fibrocystic tumor of the uterus, which weighed about sixty pounds. She is forty-four years old, and had all the diseases of childhood, and no other illness of importance. She gave birth to a full-term child when she was sixteen years old. Her menstruation had always been regular, and began to be painful about sixteen years ago, and continued so until she was operated upon. About sixteen years ago she noticed a lump in her right side, and for nine months the tumor mass grew very fast, reaching its height of growth in this time. After this period of time she was in bed eight months. During the eight months most of her pain was in the upper part of the abdomen. For the next fourteen years after this the abdominal distention seemed to get slightly less. I first saw her in November, 1906. At this time she was very much emaciated and weak. The abdomen was enormously distended. The tumor was flattened in front, in contrast to the spherical appearance of the ovarian cyst. On palpation there was more resistance to pressure than in cases of ovarian cyst. A vaginal examination did not materially aid in the diagnosis. There was no edema of the vulva or of the lower limbs. The heart and lungs were normal. An examination of the urine showed an absence of albumin and sugar.

An incision eight inches long was made, beginning about two inches above the symphysis pubis, and extending upward in the median line. After getting into the peritoneal cavity, a long curved trocar was inserted with difficulty. The wall of the tumor was very resisting, being about one and a half inches thick, and fibrous. After several attempts, the trocar was inserted, and then several gallons of foul smelling pus evacuated. At first it was thought that the trocar had entered some part of the digestive tract, and that the odor was due to gases from this source, but this was not the case. After evacuation it was discovered that the entire surface of the tumor was more or less attached by dense adhesions to the belly wall and viscera. This made it very dangerous to separate the adhesions by blunt dissection. These adhesions in some instances were ligated with catgut, then severed. Parts of the omentum were tied, then cut off and taken away with the tumor. After finding so many adhesions,

Fig. 2.—Fibrosystic Tumor of the Uterus. Case II.

and seeing that the tumor wall was composed of dense fibroid tissue, and that the liquid content was disintegrating fibroid tissue, it was decided best to do a hysterectomy. Consequently the ovarian arteries, broad ligaments, and uterine arteries were

ligated with fine silk. Then a ligature was placed around the lower part of the cervix, and the tumor mass taken away. The incision was sewed up with interrupted silkworm-gut sutures, and a drainage tube left in the lower angle of the wound. The wound was dressed with sterilized gauze and absorbent cotton. The drainage tube was removed the next day, but there had been no drainage through the tube.

She had a rise of temperature from 100° to 102° F., for several days, and suffered enough pain to require the use of morphine. There was no suppuration about the incision. About the third day after the operation, it was discovered that there was a hard, round lump, about the size of a cocoanut, in the pelvic cavity. This mass was very tender and painful. It remained for two months, and then gradually disappeared. The supposition is that this was a large blood clot which came from an oozing blood-vessel or vessels.

About six weeks after operation the patient began to cook. She has gained, since the operation, about thirty pounds. On February 24, 1908, she weighed 148 pounds, and is now perfectly well.

These two negro women were staying with relatives at the time of operation. These relatives had their usual house work and washing to do, consequently could not look after the patients very much, after they were operated upon. These negro houses were as dirty and filthy as any negro hut could be. In both of the above cases a trained nurse was present, to prepare for and assist in the operation, but after this they had very inefficient nursing.

Case III.—Mrs. ——, operated upon June 15, 1906, for ovarian cyst which weighed thirty pounds. She is forty-four years old and the mother of seven children. The youngest is fourteen years old. For several years previous to operation the abdomen began to be distended more and more. The distention produced no pain or discomfort. There was considerable loss of flesh. Menstruation has always been regular and painless. The operation was performed in the usual way. There were no adhesions and it took only about twenty minutes to complete the operation.

This patient had a comfortable home, clean surroundings, and a trained nurse; consequently, an uneventful recovery could be expected. She was in bed two weeks. Four weeks after operation she weighed ninety pounds. She weighs now 127 pounds and is in perfect health.

Cases No. I and No. II had very favorable surroundings for septic peritonitis. Case No. 1 was very favorable for infection, on account of the scales of psoriasis. From the success in these instances we conclude that such cases are not to be abandoned in the absence of hospital facilities.

The photograph in Figure 1 (this being of the patient—Case I) illustrates that ovarian cysts are roughly spherical, while Figure 2 shows that fibrocystic tumors are more or less flattened in outline. In cases of ovarian cysts, the sack is thin and yields to the pressure of the fluid, while the walls of fibrocystic tumors are less yielding and flattened. These two photographs illustrate an important point in diagnosis.

Consumption of Tobacco in France.—The total sum expended in France for tobacco in 1907 was nearly $100,000,000. This is 12.66 francs, or about $2.53, a head of population. Of this the treasury gains 92 per cent. The sale of cigarettes has risen from $200,000 in 1872 to $14,400,000 in 1907.

THE ART OF SURGICAL KNOT TYING.

By CHARLES H. DUNCAN, M.D.,
NEW YORK.
VISITING SURGEON, ST. GREGORY'S HOSPITAL.

Anything that hastens an operation and at the same time adds to its technique grace and precision, is worthy of serious consideration.

A new system of knot tying is here presented.

Fig. 1.—Reef knot.

It is of German origin and has never been used in this country as a system, though one of the single knots has been used to some extent. This system is being taught at the New York Polyclinic in Dr.

Fig. 2.—Granny knot.

John A. Bodine's Operative Course on the cadaver by his assistant, Dr. Robert E. Brennan, who introduced it in America, and when the writer, who is associated with him in the polyclinic, observed its

Fig. 3.—Surgeon's knot.

beauty, facility, and simplicity, and its superiority over the methods now advocated in textbooks, it was decided to illustrate and give it to the profession as a complete system of surgical knot tying.

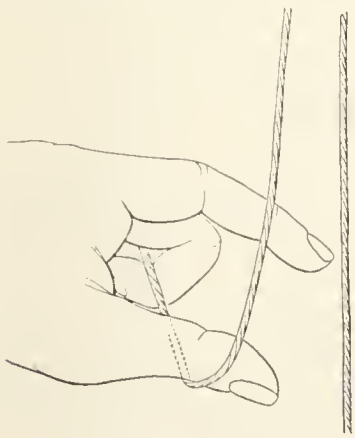

Fig. 4.—Knot No. 1, first movement.

It comprises two different single knots, each of which may be tied with either hand, the square, sailor's or reef knot (Fig. 1), and the double surgeon's knot (Fig. 3).

All single knots are tied with one hand, one end of the ligature being held passive while the other end is turned round it in the form of a loop.

Knot No. 1 (Figs. 4-8), a single knot, may be

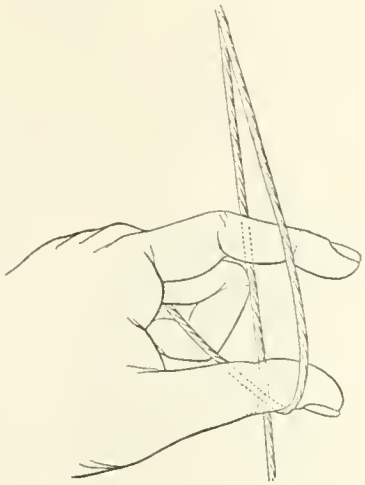

Fig. 5.—Knot No. 1; second movement.

used whenever such is necessary. It may be tied with either hand. Thus it adapts itself to the emergency of one short end of the ligature, since it may be tied with the long end, by manipulation of the

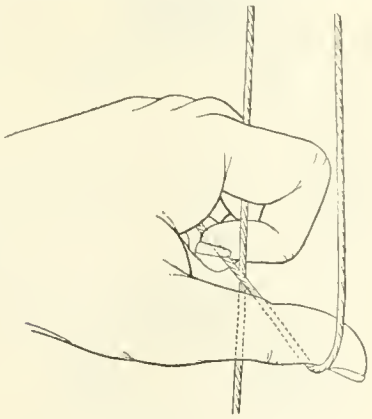

Fig. 6.—Knot No. 1; third movement.

fingers, the long end making one complete turn around the short end, forming a loop. It is recommended that it be tied with each hand with equal dexterity, for reasons that will be apparent later.

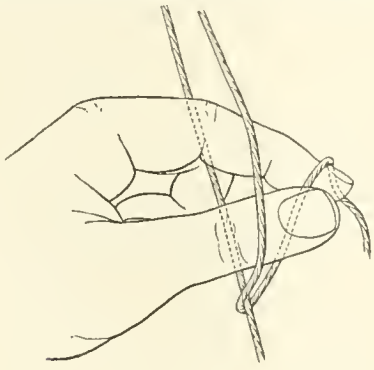

Fig. 7.—Knot No. 1; fourth movement.

If No. 1 knot is tied with the left hand, we will for the sake of referring to it, call it L. 1; if it is tied with the right hand, R. 1.

In L. 1 the manipulating end of the ligature travels around the stationary end, in a direction opposite to the hands of the clock (see Fig. 8). In R. 1 the manipulating end travels in the direction of the hands of the clock, for a right handed knot is the reverse of a left-handed knot. Since the traveling end in R. 1 travels in the opposite direction to the traveling end of L. 1, it follows that

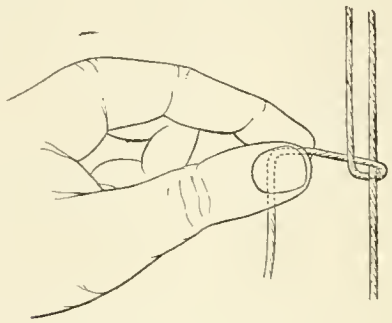

Fig. 8.—Knot No 1; final movement.

if L. 1 be followed by R. 1, it makes a square (sailor's or reef) knot, as may be easily seen by picking the knots apart.

Knot No. 4 (Figs. 9-12) is so called because the

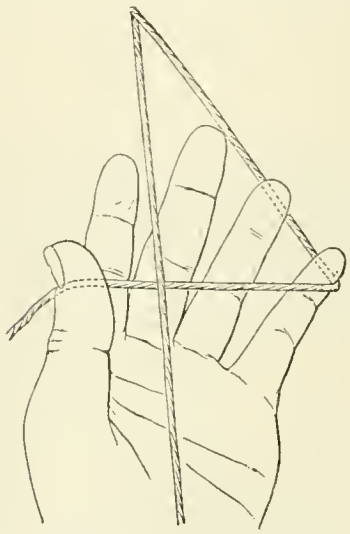

Fig. 9.—Knot No. 4; first movement.

shape the ligature assumes on the fingers before tying is that of a figure four. With the ligature spread out on the fingers as in Fig. 9, it is evident the manipulating end in L. 4 travels in the direction

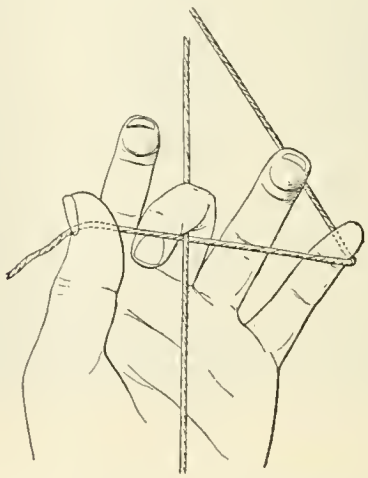

Fig. 10.—Knot No. 4; second movement.

of the hands of the clock, then L. 4 could follow L. 1 in making a square knot. This is tying a square knot with the left hand. The same thing may be done with the right hand, and it is just as

easy and simple to tie it with one hand as the other.

Now if knot No. 4 be tied with the right hand

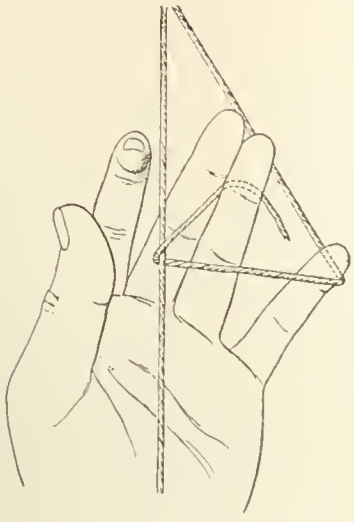

Fig. 11.—Knot No. 4, third movement.

(called R. 4), we see the manipulating end travels in a direction opposite to the hands of the clock, or in the same direction as the manipulating end in

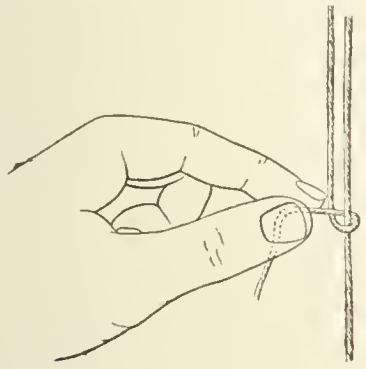

Fig. 12.—Knot No. 4; final movement.

L. 1 travels, and if it followed L. 1, would tie a granny knot; this is just what we do not wish to do.

To recapitulate for the sake of clearness:

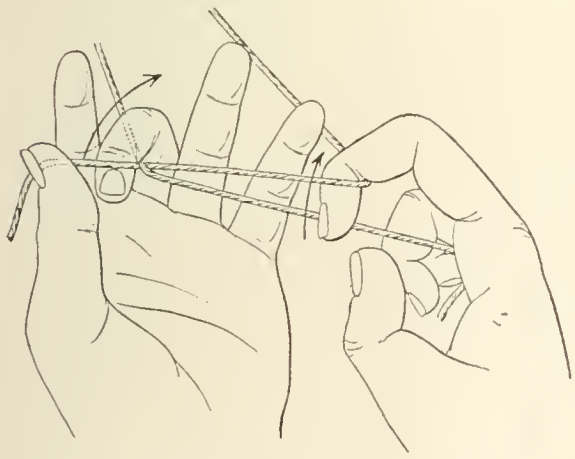

Fig. 13.—The Double or Surgeon's Knot; first movement.

L. 1 followed by R. 1 = a square knot
L. 1 followed by L. 4 = a square knot tied with the left hand
R. 1 followed by L. 1 = a square knot
R. 1 followed by R. 4 = a square knot tied with the right hand

For all practical purposes these four knots are all that are desired or needed, but if for the sake of investigation or experiment we wish to follow this system to the limit of possibilities of reef-knot tying, we will discover that there are four more square knots that can be tied equally as easy as the four given above, the only difference being that we start with No. 4 knot instead of No. 1.

L. 4 (clock-wise) followed by R. 4 (anti-clock-wise) = a square knot.
L. 4 (clock-wise) followed by L. 1 (anti-clock-wise) = a square knot tied with the left hand.
R. 4 (anti-clock-wise) followed by L. 4 (clock-wise) = a square knot.

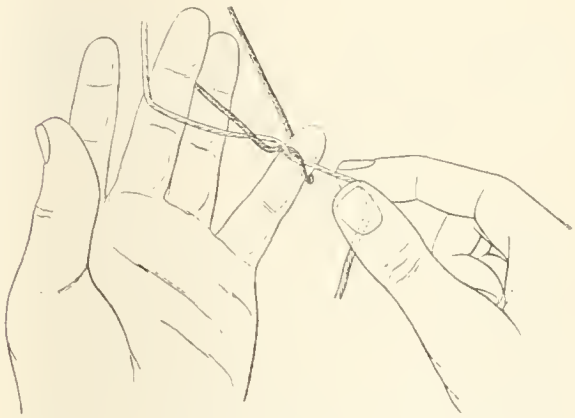

Fig. 14.—The Double or Surgeon's Knot; second movement.

R. 4 (anti-clock-wise) followed by R. 1 (clock-wise = a square knot tied with the right hand

The general rule for square, or reef-knot tying, may be stated as follows:

Never tie two knots whose traveling ends travel in the same direction, or conversely,

Always follow a knot by a knot whose traveling end travels in the opposite direction to the knot first tied.

For general surgical work it is recommended that L. 1 be used followed by R. 1 on all occasions where a square knot is desired, but with one short end of the ligature, follow L. 1 by L. 4. The reason these knots are recommended in this order is apparent when we come to the double or surgeon's knot.

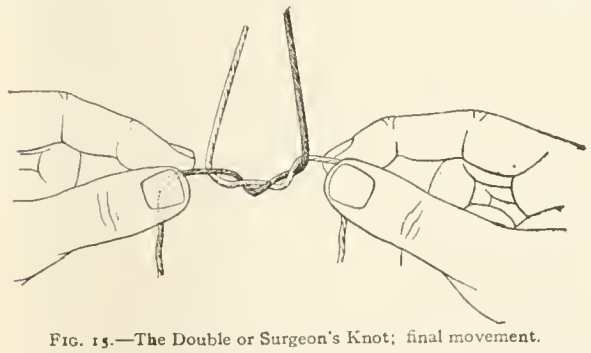

Fig. 15.—The Double or Surgeon's Knot; final movement.

This double or surgeon's knot is a combination of L. 4 and R. 1 (see Figs. 13-15). L. 4 is tied here exactly as the single L. 4 knot is tied, and the index finger of the right hand is manipulated in getting the double knot in a manner similar to the manipulation of tying the R. 1 knot. They are both tied at the same time giving the double surgeon's knot.

After the technique of knot tying is once acquired, the only thing needed to get up speed and dexterity is practice. Much can be accomplished in this direction with large gloves and fine thread. One student tied twenty-four L. 1 knots in thirty

seconds, and another twelve surgeon's knots in the same time.

By carefully studying the illustrations but little difficulty will be experienced in mastering the simple technique of this system of tying knots.

There is one error that most students seem prone to make and about which it is well to warn the beginner, and that is in regard to knot No. 1. Be sure to cross the thumb and forefinger (Fig. 5) over the passive end before attempting to bring down the revolving end of the ligature, and as soon as it is possible grasp the ligature with the thumb and forefinger and pull it through the loop (Fig. 7).

233 Lexington Avenue.

URTICARIA FOLLOWING THE SECOND ADMINISTRATION OF DIPHTHERIA ANTITOXIN.*

By ALEXANDER W. BLAIN, Jr., M.D.,
DETROIT, MICH.
SENIOR RESIDENT PHYSICIAN, HARPER HOSPITAL.

The old adage, "there is no rose without a thorn," is well exemplified by the administration of diphtheria antitoxin. It is not my object here to subtract from the value of, or your confidence in, one of the greatest therapeutic triumphs of the century just passed, but to throw some possible light upon a phenomenon following its administration, which at times becomes very annoying, if not of a serious nature—and with the further hope that extended investigation may eliminate this most distressing condition.

In my paper this evening I have not attempted to deviate from a purely clinical aspect of the phenomenon, leaving to the toxicologist or the bacteriochemist an explanation from the chemico-physiological point of view. My observations extending over the past few years have been with the products of three of our leading pharmaceutical houses, and mainly with the antidiphtheritic serum, and not the "globulins" now becoming more widely used. Our experience with the latter is as yet too limited to speak in comparison with the original "nonconcentrated" product.

The term urticaria, as used by the dermatologist, covers too broad a field. The nomenclature of the dermatologist elaborates upon the lesion, which in reality, is at most undoubtedly only a symptom and not upon the various forms of the disease. Thus, the original deviation of the word is misleading in so far as the following cases are concerned. It has seemed to me that the purely local effect of the nettle or the stings of insects should not be classed with the constitutional condition, with its gastrointestinal, renal, pulmonary, and other lesions. The condition is an angioneurosis—a constitutional and not a local disease, in which the vasomotor system is accountable for most of the lesions.

The disease so far as the following cases are concerned should be separated and placed in a different category than urticaria or hives—at least, in the restricted sense of the latter term. The angioneurotic phase of the phenomenon has long been considered, but the edema as well as gastrointestinal symptoms without autointoxication or direct irritation has not been sufficiently dwelt upon, but as I have already said, it is my purpose here to present only a clinical report.

The following records on seven cases are selected to show the etiology, conditions surrounding, and symptoms of the disease which, for lack of a better term, we would class as urticaria.

Case I. Miss A., age twenty-four, Canadian, trained nurse. Family history negative. Patient a well nourished individual, inclined to the blonde type, has always enjoyed good health, aside from a few of the infectious diseases of childhood, and four attacks of tonsillitis during the past few years. During the winter of 1905 she entered the diphtheria ward, and was given 1,000 units of antitoxin on two different occasions six weeks apart. The first caused no reaction—a slight irritation formed around the point of the second injection.

On January 24, 1907, the patient developed a sore throat. The following day a membrane appeared on the tonsils and some spots on the peritonsillar structures. A culture of the throat was taken and the patient isolated and given 3,000 units of antitoxin in the gluteal region at 6 P.M. The culture was later reported negative as regards the presence of the Klebs-Loeffler bacillus. Within twenty minutes following the administration of the serum a profuse urticaria appeared over the entire body. The edema of the periorbital tissue completely closed the eyes. The patient was greatly prostrated, respiration sighing, absence of radial pulse, complained of feeling faint and chilly, also of fullness in the throat. The bowels moved freely at 8:45 P.M., the patient complaining of cramps in the bowels and soreness in the stomach. At 9 P.M. the radial pulse became perceptible, but was thready and intermittent; 10:30 P.M., pulse low in tension and irregular; 11 P.M., pulse somewhat improved, respiration still sighing, patient very restless; 12 midnight, bowels again moved freely; 3:30 to 5 A.M. the patient slept, but was restless during sleep, urinated ounces xxv at 5:30. At 7 A.M. the pulse was 88; the patient coughing a great deal from bronchial irritation, at 6 o'clock was able to retain small amount of nourishment. Temperature went from normal to 100° F. shortly after the injection of the antitoxin, but otherwise did not go above 99. The urine contained albumin and hyaline and granular casts for several days. After a few days in bed the patient gradually recovered.

Case II. Miss G., aged twenty-three, brunette, Canadian, trained nurse. Father, mother, and seven children, all living and healthy except father, who has diabetes. Patient had scarlet fever, measles, and diphtheria during childhood.

When the patient entered the diphtheria ward she was given 1,000 units as an immunizing dose. Seven weeks later a small membrane developed on the throat, and 3,000 units of antitoxin were administered. Within five minutes following this injection a profuse urticaria covered the whole body. The tongue became very swollen, abdomen very sore, and the patient complained of extreme nausea. This condition continued for three days, when it gradually subsided. On the fourth day an inflammatory arthritis developed in all the joints of the body, including the fingers and the inferior maxilla. This painful rheumatic condition lasted three days, and then gradually subsided. During this time the patient became exceedingly cyanosed at times, and has ever since had a more or less irregular heart-beat with occasional palpitations. The urinary findings in this case were negative.

Case III. Miss H., aged twenty-three, Canadian, blonde. The patient, a well-nourished individual, had most of the diseases of childhood, but never had diphtheria. Family history negative; brother had diphtheria two years previous, at which time the present patient was given 500 units of antitoxin

*Read at the meeting of Resident House Physicians, Harper Hospital, February 11, 1908; and at a meeting of the Michigan Academy of Science, Ann Arbor, April 2, 1908.

as an immunizing dose. Upon entering the diphtheria ward she received 3,000 units of serum. This is a much larger dose than is usually given for immunizing purposes, but was given with the usual feeling that it was at least harmless, there being no 1,000-unit tubes on hand at the time. This proved to be one of the most distressing cases which I have seen in the practice of medicine.

Three days following the injection an urticaria developed insidiously, starting on the face and later covering the whole body. The eyes were swollen and shut, the tear ducts were closed and could not drain. The mouth, tongue, throat, and bronchi were also the seat of lesions. The patient had a cough and could not speak above a whisper. The rash, which completely covered the body, would respond to no treatment. Morphine, gr. ¼, and hyocine hydrobromate, gr. 1/100, were given and repeated in one hour, but failed to produce sleep or give much relief from the intense itching.

The urinary symptoms were negative. The condition subsided completely on the fourth day for about twelve hours, only to recur for two more days, when it again completely subsided. The case was truly disheartening, and consulting dermatologists failed to offer any suggestions for its relief, other than those that were tried.

Case IV. Miss R., age twenty-three, American, nurse, blonde. Family history negative. Patient had scarlet fever when a child, and has had considerable throat trouble all her life, tonsillitis every year for several years, but no diphtheria. Three years ago in February upon entering the diphtheria ward she was given 500 units. Last November she developed a sore throat with membrane, and was given 3,000 units of serum, and 4,000 more units were administered on the second day of the disease. Culture of throat later proved negative. On the following day profuse urticaria appeared, first on the legs, and gradually spread over the body. This was continuous for three days and three nights, failing to respond to all treatment. Patient complained of terrible backache, the feet were swollen and edematous. Pulse at times very rapid and again very slow. Patient was cyanosed considerably at times. Urinary findings negative.

Case V. Miss B., Canadian, nurse. Family history, negative. Except for diseases of childhood she has always been healthy. Never had diphtheria, well nourished, and inclined to blonde type. Patient had 2,000 units as an immunizing dose three years previous, with no reaction. On January 24, 1908, the patient again entered diphtheria ward, and was given 1,000 units of the "globulins." On the evening of the 30th, about a week later, a rash appeared, beginning around the eyes, soon extending over the entire body. Patient had a feeling of approaching death. This all lasted about fifteen minutes, when the symptoms completely disappeared. Four hours later they returned in a less aggravated form, lasting about one hour. Following this, pronounced rheumatic pains in the muscles, described as "growing pains," persisted for a few days.

Case VI. Miss D., aged twenty-two, blonde, American. Had measles during childhood, typhoid fever two years ago, congestion of one lung three years ago, and tonsillitis last May. During the latter illness she received 3,000 units of antitoxin. In November she received 1,000 units of serum, owing to a supposed exposure to diphtheria. A short time afterwards a slight urticaria appeared on the lower limbs. This continued until January 17, when the symptoms became more aggravated, necessitating the patient going to bed with rash over her whole body, especially the chest and abdomen, vomiting, and general abdominal tenderness and tympanites. Frequent examinations of the blood-pressure during the next few days showed that it varied from 98 to 110 mm. Daily examinations of the urine failed to reveal any casts; on January 20, however, there was a partial suppression, the patient passing only four ounces in twenty-four hours. The pulse during the following week varied from 80 to 112, and the temperature from 97° to 101° F. The pulse and temperature became normal after January 19; constipation has been a marked symptom. An examination of the blood showed the following: Polymorphonuclears, 71.75 per cent.; large lymphocytes, 7.75 per cent.; small lymphocytes, 20.25 per cent.; eosinophiles, 0.25 per cent.

The patient (April 2, 1908) is still under observation, and while the digestive disturbances and skin lesions are not so pronounced, the patient is still suffering from slight daily outbreaks of the eruption and abdominal tenderness, incapacitating her from duty.

Case VII. Dr. O., aged twenty-five, American, house physician, blond. During the previous year patient received two immunizing doses of 1,000 units in the gluteal muscles. Each time a slight rash developed about three days later around the point of injection, spreading over an area of about three inches in diameter. The area was simply a diffuse, elevated blotch with a definite outline, some parts of which were raised a little more than others, but contained no fluid. The conditions were more pronounced by irritation. This lasted a few days each time and then disappeared. The patient had never suffered from diphtheria, but had frequent attacks of tonsillitis. It was during one of these latter attacks, a supposed diphtheritic infection, that 3,000 units of serum was given on the second day of the disease. The injection was made in the abdominal muscles of the left inguinal region. Three days later a macular rash appeared in this region, first around the point of injection, and rapidly spreading over the abdomen and chest. This, together with the angina, was diagnosed as scarlet fever, and the patient was transferred from the general hospital to the scarlet fever ward. The rash itched and burned and became more intense on irritation. Two days later the sore throat had entirely disappeared, and the rash subsided to a small area around the point of injection.

The patient then got up and felt perfectly well for four days, being detained for the desquamation. Suddenly at the end of this time patient again took sick with nausea, vomiting, sore throat, rapid pulse, and appearance of a scarlatina rash within twenty-four hours. There was a marked conjunctivitis, with excessive lacrymal secretion suggestive of measles. A day following the scarlatina rash the symptoms of the serum rash again appeared in an extremely aggravating form. In the course of three days the rashes gradually disappeared, but last of all from around the area where the antitoxin was administered. Desquamation was complete, and except for a nephritis which persisted for a couple of months, the patient has not been troubled since.

It will be noted that in the above cases the conditions surrounding were all virtually the same, *i.e.* the injection of antitoxin for immunizing purposes, and the second injection for a supposed Klebs-Loeffler infection, which later proved to be only a tonsillitis with membrane or exudate; or simply as a second immunizing dose.

The majority of serum rashes coming under observation have been of an urticarial character,

though the rash is sometimes scarlatinoid in character, giving suspicions of a possible scarlatinal infection. In fact, in the latter case the differential diagnosis becomes an important issue, especially in the larger municipal contagious hospitals.

We have not had facilities for recording the percentage of rashes in our patients, since they are discharged as cured in several instances before the time of appearance. But 20 per cent. would be a conservative estimate of all those receiving the antitoxin. The rashes occurring in post-diphtheritic cases have all been of a very mild type and free from the alarming symptoms as noted in some of the above cases, except in one instance. Miss C, aged nineteen, developed diphtheria (positive bacterial examination); she was given 6,000 units on the second day of the disease, and 4,000 more units on the third day. The patient did nicely, and the symptoms gradually subsided; the membrane on the throat disappeared. The physician, who was leaving the city two days later, telephoned to give the patient 3,000 more units as a further precaution. In about six hours following the last injection the body became covered with an erythematous rash without any constitutional symptoms except for a slight rise of temperature. An exceedingly painful arthralgia developed in a few days, and paralysis of some of the muscles of the throat in about a week (the latter, of course, bears no relation to the serum). In a recent talk with the patient, over a year from the attack of diphtheria, she still complained of a severe, almost constant arthralgia affecting most of the larger joints. I simply mention this case in passing as one of possible overtreatment. At least the indications were not such as would warrant the last injection, though it is impossible to lay the blame upon the extra 3,000 units.

The problem we are dealing with here is with the second dose of the serum given some time after the first. The prevalence of blonds in the above series may be a coincidence, but we are inclined to the opinion of their extrasusceptibility. It has been claimed that the deleterious effects of antitoxin are due to the foreign animal serum and not to the antibodies contained therein. From a clinical point of view this is immaterial. The term serum as used above must be taken in its collective sense. The cases of sudden death, recently reported, appear to conform to the above Cases I. and II.

In my opinion, at least some of the deaths are due to the angioneurotic edema, and not to *status lymphaticus*, paralysis of the respiratory center, diseases of the thymus gland, etc. The histories here do not conform to those in the fatal cases. It is quite probable, however, that the blood was rendered much the same in those cases by some previous agent, thus making the individual susceptible to the antitoxin.

Conclusions.—(1) The *second* immunizing dose of antitoxin should be given with caution, especially to individuals of the blond type, regardless of how long previous the first was administered. Should an individual who has at some previous time received antitoxin become exposed to diphtheria, it is better, in my opinion, if facilities are such that the exposed person can be kept under observation, to delay the administration until symptoms of diphtheria appear. Diphtheria taken early and properly treated would be accompanied by as little danger and far less suffering than were some of the cases cited above. Further, in cases of direct exposure to diphtheria, the possibility of contracting the disease is comparatively small.

(2) In persons in whom an immunizing dose of antitoxin has been given, and who later contract diphtheria, an attempt should be made to regulate the dosage in comparison with the severity of the infection, and not to push the serum too far, and thus overneutralize the toxin, possibly producing this distressing condition.

A positive clinical diagnosis of diphtheria is often utterly impossible, regardless of the amount of experience possessed by the clinician, and consequently all suspicious cases should be treated as diphtheria, and as diphtheria by antitoxin, until proved otherwise, since the possibility of trouble caused by the antitoxin is not to be compared with that of the danger from diphtheria.

THE CONVALESCENT PERIOD, AND ITS SUCCESSFUL MANAGEMENT.

By W. PARKER WORSTER, A.M., M.D.,

NEW YORK.

INSTRUCTOR IN ELECTROTHERAPEUTICS NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.

In the early convalescent period from any disease where the case has almost terminated fatally when death seemes imminent from heart failure, and when free stimulation from drugs had been made, and the patient gains resistance very slowly, and the muscles are lax and flabby and unable to perform their duty in aiding the heart to send out the normal diastolic wave, nothing in the materia medica will act so promptly as judicious and properly applied hydrotherapy.

The muscles must aid and support the heart or else the heart must positively fail. If in the convalescence there are any head symptoms of delirium, active or low muttering, affusions are most effective, no matter what the temperature, pulse, or respirations may be. This may be done by placing the patient in a tub with water at 100°, enough to cover the hips in a sitting posture, and the operator standing on a chair pours several basins of water at 70° or lower over his head and shoulders. Nothing will arouse the dormant functions so quickly; respiration is deepened, cardiac action gains in force, and each heart beat is deeper, fuller, and firmer. The sudden impingement of a considerable volume of water with decided force intensifies the mechanical and thermic effects, and draws from the central nervous system reflex stimulus to cardiac action, assimilation, and respiration, which are of decided and unmistakable value. The rapid pulse is not due to a disordered heart, but to a disturbed vasomotor system, and although the pulse may be small and thread-like at the beginning, it will be found to have gained in force by each one of these affusions, and will continue to gain more force after each one.

Cold applied to the peripheral nerve terminals of the skin is refreshing because the stimulus is conveyed to the central nervous system by means of the shock, and thence reflected by means of the nerve centers governing them to the functions of respiration, circulation, digestion, tissue-building, and excretion upon whose functionating capacity the organs depend. Therefore, in the convalescent period the affusions are most applicable because of their flexibility of temperature, duration, and pressure. For instance, in old persons we would begin with affusions at a high temperature between 88° and 92°, and in all weakly persons the same, and brief, commencing with a single basin, and as the pulse increases in force and diminishes in frequency, increasing to two or three basins, as the case may be. The patients get so attached to them

that they look for the approaching time to take the next one.

The trunk compress at night is also a very useful method of stimulation. It consists of three thicknesses of butcher's linen, to go completely around the body from the armpits to the navel or a little below it, wet with water at 70°, and one thickness of white flannel over it pinned in front with four safety pins, tight above and tight below, causing total exclusion of air from without the flannel covering. The wet linen becomes heated by the patient's own temperature, a vapor forms under the wet compress in an effort to equalize the temperature between the body and the compress, and together with the movements of the chest in respiration, thus keeping up a certain amount of friction upon the capillaries and dilating them; the right heart is relieved, not by *vis a tergo*, but by a *vis a fronte* formed by broadening the blood stream in the capillaries, whose enhanced tonicity propels the blood onward. This is hydrotherapy in a nutshell. Arterial tension is increased. The right heart being relieved of its fullness, on account of there being more room in the arteries, is able to contract further, and each contraction is fuller and firmer. The most important effect of cold is the aid and support it furnishes the central nervous system, which bears the whole brunt of the fight. To show how cold will stimulate the function of assimilation, it is a well-known fact that patients convalescing from pneumonia, typhoid fever, or other infectious diseases, after the water treatment acquire immediately a ravenous appetite, in contradistinction to those convalescing after the expectant plan. In the latter the functions may take months or even years to resume their normal condition, if they ever do.

Still another good mode of applying water when the patient is in bed and too weak to be handled roughly is what is called the "ablution." The patient's feet and legs to the knees are wrapped up snugly in a thick blanket, and the patient is rapidly washed down with water at 70° to 80°, chest, and back, and arms to elbows, and thighs to the knees with the flat of the hand or a piece of gauze, going over the parts several times and squeezing water freely and rubbing with hand or gauze; he is then rapidly or partly dried, given a cup of warm liquid food or milk, and left to sleep, which he generally does for a couple of hours. In order that the effect upon the heart be continuous it is necessary to repeat the application every three hours in desperate cases. In many cases, as in fever and other depressed conditions, when the pulse is rapid and small a rapid ablution at 70° would be of better service on account of its brevity and minimum of disturbance to the patient, when a prolonged Brand bath would be harmful.

The reactive capacity of the patient must be studied to establish his ability to withstand the proper gradation of cold. This may be obtained by passing the back of the nail of the forefinger of the right hand across the abdomen or chest and increasing the pressure on the second stroke made parallel to the first. According to the deep reddening of the skin and the celerity of the blood in following the nail, after a little practice the reactive capacity of the patient may be readily judged. In the eruptive fevers, such as scarlatina, brief affusions at 70° every hour are most useful—no full baths, no friction, on account of the tender skin and eruption. It is dangerous to give stimulants or any other drugs in the convalescent period unless the circulation and blood-pressure are thoroughly established. They only make the enfeebled heart work away in these desperate conditions like the locomotive which has lost its resistance by slippery tracks. The thing to do is to put sand on the track and restore the resistance. The cold bath with friction, or the ablution with the hand, or the affusion with a good impact of water, or any other hydriatic procedure, according to the patient's reactive capacity, properly given, by the enhancement of the contraction and subsequent dilatation of the capillary vessels, and the filling of them, restores the normal tone and resistance to the heart, and thus reinstates lost blood-pressure. Shock, by cold to the peripheral nerve terminals and reflex stimulus to the cutaneous vessels, is the only object in view, and not the heart.

Success or failure depends upon the exact execution of any hydriatic procedure, and familiarity with technical detail is just as essential for the judicious and effective application of any form of water as is the technique of a surgical procedure to the surgeon. The heart's action can be stimulated and awakened more promptly by cold applied to the peripheral nerve terminals of the skin than by any other means, because the shock of the cold (and the colder the water the more pronounced is the reaction) is always conveyed to the central nervous system and thence reflected to the three chief blood-pressures, (*a*) the pressure behind the column—the heart; (*b*) the pressure on the sides of the column—the muscular coats of the arteries and the elastic fibers of the arterioles, and (*c*) the pressure in front of the column—the normal elasticity of the capillaries. In this manner is blood-pressure maintained.

As an illustration of the power of cold for good I may mention how red and warm the hands get in making snowballs and packing the snow hard with the hands. The warmth and ruddy hue of the hands demonstrates the fullness and dilatation of the capillary vessels with arterial blood, consequently the heart is relieved of its fullness and invigorated. In the convalescent period all these methods of management are useful if carried out as technically correct as possible. They increase oxygenation and promote hematosis more rapidly than any other means, and no matter how small and thread-like the pulse may be, it has always gained a little in force and diminished a little in frequency after each application.

621 West One Hundred and Seventy-ninth Street.

Uterine Infection in the Course of Pregnancy and the Puerperal State.—F. Menod studies infection from the beginning of pregnancy to the end of delivery. It may result from a fault of technique, or may extend secondarily to the uterus. First the author considers criminal abortion. Curettage is often not advisable as a remedy. We should first determine the extent of infection, and should be guided by the general and local conditions. When the membranes are not ruptured and there is little flow, conservative measures should be adopted and the pregnancy may continue. Curettage would create a source of entrance for infection by producing a wound. The epoch of interference is generally at the time of pregnancy when hemorrhage would be greatest and most difficult to control. The temperature curve will be an important guide. When the membranes have ruptured curettage is more necessary, but is better done after the symptoms of infection have passed. In noncriminal abortion the cause is generally inflammation of the adnexa. The indication is to aid nature and not be too quick to operate. Puerperal infection may result from faulty technique or infection from without, as the adnexa. Any vaginal source of infection must be sought, retention of placental remains looked for, and the condition of the uterus examined. Quinine, ergotine, and cafeine are useful. Large intrauterine douches are valuable after being sure that the uterus is empty.—*Journal de Médecine et de Chirurgie.*

MEDICAL RECORD.

A Weekly Journal of Medicine and Surgery.

THOMAS L. STEDMAN, A.M., M.D., EDITOR.

WM. WOOD & CO., 51 FIFTH AVENUE.

New York, June 6, 1908.

THE CANCER PROBLEM.

CANCER is recognized as the second great scourge of civilized man after tuberculosis, if indeed it is not the chief and worst of the ills of human flesh. Its terrible prevalence is shown by the facts that every eighth woman who has passed the age of thirty-five years is doomed to perish from this disease, and that malignant growths are found in one of every twelve hospital autopsies. Tuberculosis, there is every reason to hope, is on the road to extinction, though the way is still long before that goal will be reached; its cause is known—at least in a general way, although the exact mode of invasion is not yet absolutely determined, its prevention is almost within reach, and it is, if taken in time, curable. But cancer remains a mystery in its causation, and its prevention and definite cure are as yet obtainable only by mutilation, and even then in only a small proportion of cases. This is not because the study of the disease is neglected, for there is no physical ill that is the subject of more earnest study by skilled investigators all over the world than this, but none that has as yet rewarded its students less. That the day will come, however, when cancer shall be conquered no one can doubt who believes in the final success of human endeavor, and that this day is even now dawning is the hope aroused by the inspiriting address delivered by Dr. Crile of Cleveland before the American Medical Association at the annual session in Chicago this week.

Until the cause or causes of malignant growths, both sarcoma and carcinoma, shall have been discovered the treatment must remain surgical, which, even though occasionally successful, is painfully uncertain and only accidentally curative, since it only removes the local manifestation of the disease, and does not alter the constitutional defect, upon which the possibility of such growth depends. It is like the accidental deflection of a bullet by the button of a soldier's coat or the watch or wallet in his pocket; the lucky chance saves him from death by that particular bullet, but offers only a superstitious hope of immunity from a second missile. The fact of natural or acquired immunity, of which Dr. Crile speaks, disproves the theory of the local origin of cancer and strengthens the almost universal belief of the laity, shared by a large proportion of the profession, that operation, while necessary, indeed offering the only hope of life, is but a makeshift and a confession of therapeutic impotence. But the discovery of immunity does infinitely more than disprove a theory; it opens up the possibility of eventual success in the treatment of cancer, the mere thought of which is pulse-quickening. Cancer immunity in mice has long been recognized, but the experimental cure of sarcoma in dogs by transfusion of the blood of immune dogs, as obtained in nine out of eleven cases by Crile and Beebe, is a practical therapeutic application of wonderful promise. The trials of the method on man are too recent to warrant any certain deductions, yet the fact of freedom from recurrence for sixteen months in one case with exceedingly bad prognosis is significant, at least.

The diagnostic application of hemolysis, to which Crile refers, is another very important and interesting fact. The entire article, indeed, is worthy of the most careful study, and must be regarded as one of the most valuable contributions to the literature of cancer that has yet appeared. It can but inspire other workers to fresh efforts, and the possibility it suggests of the eventual treatment of malignant disease without mutilation and with a reasonable hope of actual cure is full of comfort for the future. It has at least cast a faint ray of light into a region which has hitherto been one of almost abysmal gloom.

THE SPECIFICITY OF VON PIRQUET'S CUTANEOUS TUBERCULIN REACTION.

ON the assumption that the body is sensitized by the first injection of a toxin, reacting more quickly to a second injection (the principle of "allergie"), v. Pirquet laid great stress on the diagnostic value of the skin reaction to tuberculin. He claimed that the body which had once been in combat with the tubercle bacillus, and therefore contained a tubercle toxin, responded with a typical skin papule on being vaccinated with tuberculin. For practical purposes, however, he restricted this test to children, admitting that it was of little value in adults, as ninety per cent. of them gave a positive reaction. Most investigators agree with v. Pirquet in that it is of diagnostic value in children. To test its specificity further, R. Entz (*Wiener klinische Wochenschrift*, March 19, 1908) tried the effect of various other toxins in adults, using diphtheria, typhoid, paratyphoid, and pyocyaneus toxins. In 110 adults he obtained seventy-five per cent. positive reactions with tuberculin, both in those who were tuberculous and in those who revealed no tuberculosis clinically. The tuberculous and nontuberculous patients also reacted alike to the other toxins, giving a positive reaction in fifty per cent. The reaction caused by the tuberculin lasted a little longer, but the resulting papule could not be differentiated microscopically from the one caused by the other toxins. Entz also vaccinated 126 children, from a few months to fourteen years old, with tuberculin, diphtheria, typhoid, paratyphoid, cholera, and symptomatic anthrax toxin. Sixty-eight per cent. of those clinically tuberculous, and forty-five per cent. of the others, gave a positive reaction with tuberculin. The other toxins, however, gave as many positive reactions as the tuberculin, and the papules again all looked alike. Seventy-five per cent. of the children who had diphtheria, or who had received an immunizing dose of diphtheria antitoxin, showed a positive reaction, as did

also thirty-one per cent. of those who never had diphtheria or an antitoxin injection. Those who reacted positively to the cholera and symptomatic anthrax toxins had certainly never been infected with the cholera or symptomatic anthrax bacillus, so that the positive reactions with these and the other toxins cannot be explained on the principle of "allergie," on which v. Pirquet explains the positive reaction after vaccination with tuberculin. From these findings Entz argues that the tuberculin reaction is similar to the others, and is probably nothing else than an expression of an individual local sensitiveness to the toxin.

Schläpfer (*Beiträge zur Klinik der Tuberkulose*, Vol. IX., No. 2) vaccinated patients in two places with tuberculin. In one place the skin was normal, in the other he had caused a hyperemia with a mustard plaster applied for twenty minutes. He found that in those patients in whom the hyperemia lasted twenty-four to forty-eight hours, the tuberculin caused no reaction over the hyperemic area though it caused one on the normal skin of the same patient. When the hyperemia lasted only six to ten hours, the mustard plaster having been left on the same length of time, a mild reaction was found in both places, which goes to show that the activity of the skin plays a rôle in the outcome of the vaccination. Entz's observations and the influence of hyperemia on the reaction, bring up the question whether a positive reaction after vaccination with tuberculin is possibly nothing else than a local process, in no way related to the immunizing processes in the body, and one that cannot be called specific in the sense that v. Pirquet claims. At any rate, some doubt is thrown on the diagnostic value of this test, even in children.

DIRECT TRANSFUSION AS A THERAPEUTIC MEASURE.

In 1666 Jean Denis first attempted blood transfusion in a human being. In the following years it was tried everywhere, usually by the indirect method, though at times by the direct from vessel to vessel by means of a cannula. Some successes were reported, but after numerous fatalities the procedure was dropped, in fact forbidden by the French government. In the beginning of the nineteenth century it was again taken up. Investigators proved that nondefibrinated blood was dangerous, causing multiple thrombosis, that the blood of one species injected into an animal of another species caused hemolysis, and that blood might functionate normally if transfused into an animal of the same species. Finally, in 1883, it was agreed that only direct transfusion from artery to vein was permissible. On account of the uncertain and cumbersome methods of anastomosis, however, transfusion was not practised.

With the recent development of practical means of blood-vessel anastomosis, direct arteriovenous transfusion again came within the realm of possibility. In 1898 Crile proved experimentally and to some extent clinically that transfusion is the best treatment for illuminating gas poisoning and for every degree of hemorrhage. Recently R. Ottenberg (*Annals of Surgery*, April, 1908) tried it in two cases of secondary anemia with good immediate results. The transfusion lasted thirty-five minutes, during which time the condition of the patient improved visibly. The pallid lips became red, breathing became easier, the mental condition changed from semi-stupor to almost exhilaration. The percentage of hemoglobin rose from fifteen to thirty-five, the red cells from 600,000 to 1,096,000 per cubic millimeter. He used the ring method of anastomosis and describes it in detail. Because of its simplicity he prefers it to Carrel's suture method for temporary anastomosis in direct transfusion. While it is now universally admitted that the blood of one healthy animal is physiologically interchangeable with that of another healthy animal of the same species, Ottenberg reminds us that there are cases on record of fatal hemolysis after transfusion in cases of pernicious anemia. This indicates that in some diseased conditions mixture of blood, even of the same species, is dangerous. In one of his patients he first determined whether hemolysis might occur; his method, however, was cumbersome.

It may be said that in certain cases direct transfusion from artery to vein is a safe and valuable therapeutic measure. However, not until we possess a simple clinical test to determine beforehand whether hemolysis is likely to occur and not until we have a better knowledge of the diseases which contraindicate transfusion, can it be generally recommended.

THE OPERATIVE TREATMENT OF PULMONARY EMPHYSEMA.

Some years ago A. Freund advanced a theory with respect to emphysema of the lungs. He claimed it was due to pathological changes in the costal cartilages which caused the chest to become barrel shaped, giving it the appearance as if it were in a permanent inspiratory position. He held that this position of the bony thorax caused a constant abnormal tugging on the lungs which in turn brought about the emphysema. Most observers consider the barrel-shaped chest as secondary to the emphysema, though some admit that there are children who have a congenital barrel-shaped chest and who develop emphysema early in life, there being a congenital disproportion between the size of the thorax and the lungs. Whether the barrel-shaped chest is primary or secondary, it is dependent, Freund says, on changes in the costal cartilages. The latter gradually become calcified, are pushed forward, and thus give the characteristic rotundity to the thorax, the disease usually beginning in the second or third costal cartilage. On a cadaver with a barrel-shaped chest the latter sinks back into the expiratory position after several costal cartilages have been cut. This observation led Freund to suggest cutting the costal cartilages in patients with emphysema, as in this way the rigid dilated thorax becomes mobilized and the dilated lung is permitted to retract. Recently three cases were reported as relieved by this rather heroic treatment. In the *Semaine Médicale*, No. 45, 1907, F. Lejars again draws attention to this method of treatment. He advises resecting two centimeters of the costal cartilages, taking care not to injure the insertion of the triangularis sterni. He does a subperichondral resection of five or six cartilages on each side. While this treatment mobilizes the thorax it would seem to do but little good in

those cases in which the barrel-shaped chest is secondary to the emphysema, yet it might be of value in cases in which one was certain that the abnormal bony thorax existed a long time before subjective symptoms of emphysema set in.

Starch in the Diet of Infants.

A few years ago the leading pediatrists taught that the addition of starchy food to the diet of infants is contraindicated, this teaching being supported by the alleged absence of the diastatic ferment of the pancreas in young infants. Later researches have disproved the latter assumption and physicians have turned to starchy foods in many difficult feeding problems. Dr. Hans Rietschel (*Deutsche medizinische Wochenschrift,* May 7, 1908) considers that the use of starch is especially indicated in those remarkable cases in which a milk diet is followed by malnutrition with the clinical picture of acidosis. Fat seems to be the badly borne element, and the carbohydrates, both sugar and starches, ought therefore be liberally used for fairly long periods of time. In the acute digestive disturbances, on the other hand, starchy food is to be used simply as a temporary diet, while the digestive tract of the child is regaining its normal tolerance toward proteids and fats. Exclusive starchy food has its evil consequences that range from slight malnutrition to marantic conditions, accompanied by tetany. While, therefore, the use of starchy food under the direction of a physician may be of great value in selected cases, ignorant adherence to a starchy diet, because of the apparent initial success with it in many cases, is to be strongly deprecated.

Operations for Hernia in Infancy.

The general opinion of surgeons is not favorable to early operative interference in cases of hernia of infants. On *à priori* grounds it is usually thought that such serious procedures are not borne as well in the tender age of the first year or two, as at a later period. Writing in the *Münchener medizinishe Wochenschrift* of May 12, 1908, Grossmann combats this opinion and gives instructive statistics of his cases. During a three years' service as surgeon to a children's hospital he performed one hundred and eleven operations for hernia, ninety of which were inguinal and twenty-one umbilical. Twenty-eight of the children were under one year of age, indeed ten of them were younger than three months. Most of the cases had been unsuccessfully treated before the operation by manual reposition, massage, trusses, etc. The results of the operations are quite remarkable: mortality was zero, in no case was there even any local wound disturbance, and all the patients were cured. Dr. Grossmann's results bid fair to change our attitude toward the advisability of operating in cases of hernia in infants. Such interference, with correct technique, appears to be relatively without danger, and, of course, offers much better chance of cure than conservative treatment.

Focal Symptoms in Diffuse Brain Affections.

Focal symptoms are usually looked upon by the surgeons as indications of local disease of the brain; their character and site guide him in choosing the spot for opening the skull in order to reach the portion of the brain involved in the disease. It is, however, to be remembered that focal symptoms may appear in diffuse disease where operation is not indicated. Saenger (*Münchener medizinische Wochenschrift,* May 12, 1908) reports several cases in which a mistaken diagnosis of local disease was thus made. An especially frequent cause for such focal signs seems to have been tuberculous meningitis. Other cases were those of diffuse sarcomatosis, diffuse leptomeningitis, chronic hydrocephalus, and arteriosclerosis of the cerebral vessels. The surgeon must therefore be on his guard against too hasty an assumption that in the presence of focal symptoms local disease of the brain alone exists. In many cases, of course, an exploratory operation is advisable, even when the diagnosis is very doubtful; lumbar puncture, however, ought to be frequently performed, for it may reveal the existence of a general infection of the brain or the meninges and thus contraindicate operative interference.

News of the Week.

Hospital of the Rockefeller Institute.—In the following letter to the Board of Governors of the Rockefeller Institute Mr. John D. Rockefeller, Jr., announces the addition of a hospital to the other departments of the institute: "Understanding that in the judgment of your board a hospital building is desirable in order to facilitate the work of research for which the institute was founded, my father will provide for the purchase of land and the erection and equipment of a suitable hospital building, whatever amount may be necessary, up to a total of $500,000, payments to be made as the work progresses. My father thus enlarges the scope and possibilities of the institute in grateful recognition of the services of Dr. Simon Flexner, as director, rendered in those orderly and progressive scientific investigations, which, sanctioned and encouraged by your board and aided by learned associates and assistants, led him at length to the discovery of a cure for epidemic cerebrospinal meningitis."

Endowment of the Massachusetts College of Pharmacy.—At the commencement exercises of this institution, held on May 14, it was announced that the college had acquired an endowment fund amounting to $150,000 by the terms of the will of Warren D. Potter. Mr. Potter, who was a wholesale druggist, died a number of years ago, and by the provisions of his will a residue of his estate reverted to the college two years after the death of his wife.

A Donation to the King Edward Hospital Fund.—Lord Mountstephen has given 5,000 shares of the Great Northern Railroad to the King Edward Hospital Fund in London. At the present quotations this gift is valued at about $600,000. Lord Mountstephen had already given securities to the value of $2,000,000 to the same fund.

Pensions to the Widows of Medical Investigators.—Congress has granted a pension of $1,500 a year to the widow of Dr. Jesse W. Lazear, who died of yellow fever experimentally induced, and the same amount to the widow of Major James Carroll, who died of heart disease, resulting from an attack of yellow fever also experimentally induced. It will be remembered that both of these men were members of the Army Commission, under the late Major Reed, which studied yellow fever in Cuba and confirmed Finlay's theory that the disease is spread through the agency of mosquitos.

"Zeitschrift fuer Laryngologie, Rhinologie und ihre Grenzgebiete."—This is the title of a new nose and throat journal edited by Dr. Felix Blumen-

thal of Wiesbaden and published by Curt Kabitzsch of Würzburg. The departments consist of original articles, abstracts, bibliography, book reviews, society reports, etc. The initial number contains some ten original contributions, and if these are examples of what are to follow the new publication will attain an enviable reputation. We would make special mention of "A Case of Congenital Laryngeal Air-sac in a Child of Sixteen Days," by Kan; "Congenital Membranous Formation in the Larynx," by Hansburg; and "Amputation of the Epiglottis in Tuberculosis of the Larynx," by Möller. The journal is well printed, and of an attractive appearance.

Pneumonia in Chicago.—The City Health Department is gaining in its fight against pneumonia in Chicago. During the first four months of 1908 the number of deaths was 712 less than in the same period of 1907, and of this saving 413 was in pneumonia. Much the largest factor in this decrease of deaths from pneumonia has been better ventilation, especially in homes.

The Control of Tuberculosis in Cattle.—New York State has adopted the Bang system of dealing with tuberculosis in the dairy herds. According to this plan, animals which react to the tuberculin test, but show no physical signs, are placed in herds separate from the healthy animals and used for breeding purposes only. As soon, however, as they develop physical signs they are slaughtered. The stables previously occupied by the diseased animals are thoroughly disinfected before they can be used for cattle again. The healthy calves from the herd of cows reacting to tuberculin, but showing no physical signs, are used to replenish the healthy herd.

Progress of the Prohibition Sentiment.—North Carolina is the latest State to vote in favor of forbidding the sale of liquor. At the election recently held a majority of the counties went dry. The list of prohibition States now includes Maine, Kansas, North Dakota, Georgia, Alabama, Mississippi, North Carolina, and Oklahoma.

Fraudulent Patent Medicine Testimonials.—A young woman of this city has recovered a verdict for $6,000 against a patent medicine company for publishing a picture of her without her consent and a testimonial which she never wrote or signed. The plaintiff testified that she was told a lady admired her appearance so much that she wanted her to have a photograph taken. The lady said she would pay the photographer for the dozen pictures on condition that she might keep one for herself. As for the testimonial of cure of uterine trouble by means of the medicine, that was written and signed by another person, without the plaintiff's knowledge or consent. The publication of the picture and testimonial in the newspapers brought so much ridicule upon the young woman that she was forced to give up her employment.

Dental Clinics for School Children.—A movement is on foot for the establishment of a number of free dental clinics for the benefit of the children of the public schools in this city. The plan originated with the supporters of Greenwich House, the Jones Street settlement organization, though it has been already carried out to a greater or lesser extent in London, Boston, and other cities at home and abroad.

A Scourge of Scorpions.—It is reported from San Cristobal de la Barranca, Mexico, that scorpions have appeared recently in great numbers in the town, and that many persons have been bitten by them, fourteen young children so bitten having died.

Suicide in Russia.—During the past three months 255 suicides have been reported in St. Petersburg, eighteen having occurred in one day the latter part of May. The cause alleged for most of the cases was despondency, due in some to destitution.

Cholera in the Philippines.—During the last four weeks cholera has appeared in the provinces of Pangasinan and Capiz. In the former four cities are infected, and in Capiz there have been 231 cases since the first of the year.

Green Cross Ambulances.—Owing to the protest of the Red Cross Society against the use of its emblem, the ambulances of Bellevue and allied hospitals will hereafter carry a green cross.

A Milk Fed Horse.—A French horse, called Azote, has been entered for the Derby. The horse has no particular pedigree to boast of, but enjoys the distinction of never having tasted oats or corn, having been raised entirely on a dried milk food, of which he eats seventeen pounds a day, with an occasional small allowance of hay. It is claimed by the owner of the animal that a horse so fed is stronger and in better condition every way than one brought up on the ordinary vegetarian diet.

Dr. Baruch at Winternitz's Clinic.—At the closing session of Winternitz's post-graduate course in hydrotherapy at Vienna, Dr. Simon Baruch of this city was introduced to the students by Winternitz, who spoke of him as a former pupil and one who had brought honor upon the Vienna clinic by his propaganda of hydrotherapy in America. Baruch delivered a brief address, giving the history of the spread of this therapeutic measure in the United States.

Dr. John H. McCollum has been appointed to the professorship of infectious diseases at the Harvard Medical School. He was for many years city physician of Boston and superintendent of the department of contagious diseases of the Boston City Hospital.

Dr. Peter E. Hughes of Brooklyn Borough has been appointed medical examiner of the Comptroller's Department of New York, to succeed Dr. C. J. Pflug.

Dr. DeSantos Saxe of New York has been appointed instructor in genitourinary diseases in the New York Post-Graduate Medical School and Hospital. The appointment was made on the basis of a competition, each competing candidate presenting an original thesis.

An International Association for Cancer Research was formed in Berlin May 22. The objects are to promote the care of patients suffering from the disease, to collect and publish statistics, to establish an international center of information on this subject, to publish an international journal, and to organize international congresses.

The American Hospital Association.—The tenth annual conference of this association will be held at Toronto on September 22, 23, 24, and 25, 1908. The program of the convention will cover the varied interests of hospitals, large and small; and besides the papers, which will be presented by members of the association and by the several subdivisions of the Committee on Hospital Progress, there will be addresses and papers by guests who have been invited to participate in the conference.

Missouri State Medical Society.—The annual session of this society was held at Springfield May

20, 21, and 22. The following officers were elected: *President,* Dr. A. R. Kieffer of St. Louis; *Secretary,* Dr. A. W. McAllister, Jr., of Kansas City; *Treasurer,* Dr. J. F. Welsh of Salisbury; *Orator on Medicine,* Dr. R. L. Goodler of Hannibal; *Orator on Surgery,* Dr. F. J. Lutz of St. Louis. Jefferson City was chosen as the place of meeting in May, 1909.

The New Hampshire State Medical Society held its one hundred and seventeenth annual meeting at Concord the third week in May. The following officers were elected: *President,* John M. Gile, Hanover; *Vice-President,* Frank Blaisdell, Goffstown; *Councillors,* Belknap county, A. H. Harriman, Laconia; Grafton county, M. S. Woodman, West Lebanon; *Trustee for three years,* W. T. Smith, Hanover; *Delegate to Dartmouth Medical College* for two years, A. C. Heffenger, Portsmouth; *Anniversary Chairman,* H. N. Kingsford, Hanover; *Necrologist,* E. E. Graves, Penacook.

The Council of the New Brunswick Physicians and Surgeons, which met at Fredericton the third week in May, elected the following officers: *President,* Dr. Murray McLaren; *Registrar,* Dr. Stewart Skinner; *Treasurer,* Dr. Thos. Walker; *Examiners,* Drs. Skinner, Atherton, Inches, T. D. Walker, Geo. A. B. Wills, J. W. Daniel.

The Montana State Medical Association.—The annual meeting of this society was held in Butte during the second week in May. The election of officers resulted in the following choice: *President,* Dr. I. D. Freund of Butte; *First Vice-President,* Dr. A. Hershey of Helena; *Second Vice-President,* Dr. C. W. Jump of Bozeman; *Third Vice-President,* Dr. E. F. Dodds of Missoula; *Secretary,* Dr. Grace Cahoon of Butte; *Treasurer,* Dr. C. T. Pigot of Butte; *Delegate to the American Medical Association,* Dr. Donald Campbell of Butte. The next annual session will be held at Missoula in May, 1909.

The Nebraska State Medical Association.—At the annual meeting of this society, held in Lincoln during the third week in May, the following officers were elected: *President,* Dr. L. M. Shaw of Osceola; *First Vice-President,* Dr. F. E. Coulter of Omaha; *Second Vice-President,* Dr. C. P. Fall of Beatrice; *Delegate to the American Medical Association,* Dr. Harold Gifford of Omaha; *Alternate,* Dr. A. R. Mitchell of Lincoln; *Councillors,* Dr. J. P. Gilligan of O'Neill, Dr. W. J. Birkofer of Gothenburg, Dr. N. T. Johnson of Upland, Dr. D. T. Guigley of North Platte, and Dr. H. H. Bellwood of Alliance.

Iowa State Medical Society.—At the annual meeting of this society, held during the third week in May, the following officers were elected: *President,* E. F. Wahren of Fort Madison; *Vice-President,* Dr. F. G. Murphy of Mason City; *Secretary,* Dr. V. L. Treynor of Council Bluffs; *Treasurer,* Dr. W. B. Small of Waterloo.

The Iowa State Society of Medical Women held its eleventh annual meeting at Des Moines on May 19. The following officers were elected: *President,* Dr. Agnes Eichelberger of Sioux City; *First Vice-President,* Dr. Lily Kinnier of Dubuque; *Second Vice-President,* Dr. Lena L. Means of Des Moines; *Treasurer,* Dr. Frisbie of Des Moines; *Secretary,* Dr. Georgia Stewart.

The North Dakota State Medical Society met in annual session at Grand Forks on May 15 and 16. The following officers were elected: *President,* M. A. Beaudeaux, Fargo; *First Vice-President,* Dr. J. A. Countryman of Grafton; *Second Vice-President,* Dr. John D. Taylor, Grand Forks; *Third Vice-President,* Dr. R. A. Beck of Lakota; *Secretary,* Dr. Rowe, Casselton; *Treasurer,* Dr. John Taylor, Minot; *Councillors,* Dr. H. M. Wheeler, Grand Forks; Dr. F. R. Smyth, Bismarck; Dr. George Carpenter, Fargo.

The Utah State Medical Association.—The fourteenth annual meeting of this society was held at Salt Lake City during the second week in May. The election of officers resulted as follows: *President,* Dr. E. C. Rich of Ogden; *First Vice-President,* Dr. L. W. Snow of Salt Lake City; *Second Vice-President,* Dr. W. W. Woodring of Mount Pleasant; *Third Vice-President,* Dr. G. W. States of Franklin, Ida.; *Secretary,* Dr. W. Browne Ewing; *Treasurer,* Dr. J. W. Harrison; *Delegate to the American Medical Association,* Dr. Baldwin; *Alternate,* Dr. F. W. Taylor of Ogden. The next meeting will be held in Ogden some time during the early part of October, 1909.

The Arkansas State Medical Society held its annual meeting at Little Rock on May 15 and 16. The officers elected for the ensuing year were as follows: *President,* Dr. J. P. Clegg, Siloam Springs; *First Vice-President,* Dr. E. K. Williams, Arkadelphia; *Second Vice-President,* Dr. J. L. Hall, Pocahontas; *Third Vice-President,* Dr. D. D. Luck, Pine Bluff; *Secretary,* Dr. Morgan Smith, Little Rock; *Treasurer,* Dr. J. W. Scales, Pine Bluff; *Councillors,* Second District, Dr. H. O. Walker, Newport; Fourth District, Dr. William Breathitt, Pine Bluff; Sixth District, Dr. J. H. Weaver, Hope; Eighth District, Dr. C. P. Meriwether, Little Rock; Tenth District, Dr. F. B. Young, Springdale; *Delegates to the American Medical Association,* Dr. C. C. Stephenson, Little Rock; *Alternates,* Dr. G. A. Warren, Black Rock; Dr. B. Hackett, Fort Smith. The next meeting will be held at Pine Bluff in May, 1909.

The Louisiana State Medical Society met in annual session at Alexandria on May 12, 13, and 14. The following officers were elected to serve for the ensuing year: *President,* Dr. E. Denegre Martin, New Orleans; *First Vice-President,* Dr. J. B. Hargrove, Natchitoches; *Second Vice-President,* Dr. C. J. Gremillion, Alexandria; *Third Vice-President,* Dr. John Callan, New Orleans; *Secretary,* Dr. E. M. Hummell, New Orleans; *Treasurer,* Dr. C. C. Bass, New Orleans. *Councillors:* First Congressional District, Dr. P. E. Archinard, New Orleans; Second, Dr. E. J. Graner, New Orleans; Third, Dr. Allan Eustis, Abbeville; Fourth, Dr. J. L. Scales, Alden Bridge; Fifth, Dr. E. Dunbar Newell, St. Joseph; Sixth, Dr. C. N. Sitman, Greensburg; Seventh, Dr. R. O. Simmons, Alexandria.

Obituary Notes.—Dr. Colin G. Strong died May 7 at Los Angeles, aged 81 years. He was born in Edinburgh, his father being U. S. Consul there. He served during the Civil War as surgeon of an Iowa regiment of volunteers. For a number of years he had lived in San Francisco.

Dr. G. F. Webber of Fairfield, Me., died on May 11 at the age of 55 years. He was born in Litchfield and was graduated from the Boudoin Medical School in 1879. He practised first at Lisbon Falls, Me., then at Waltham, Mass., and finally at Fairfield, Me.

Dr. A. E. Field died at his home in Barre, Vt., on May 9, at the age of 88 years. He was a graduate of Dartmouth College in 1846.

Dr. Louis L. Hintz died at Marion, Ark., on May 9, at the age of 40 years. He was born in New Orleans and was a graduate of the Memphis Hospital Medical College in 1890. He practised in Memphis a number of years before going to Marion.

Dr. Ernest W. Bennett of Worcester, Mass., died on May 19, at the age of 41 years. He was a graduate of the Medical Department of the University of Vermont in the class of 1897.

Dr. M. S. Corey of Fredonia, N. Y., died May 26, at the age of 81 years. He was born in Islip, L. I., and studied medicine at the University of Buffalo. He retired from practice sixteen years ago.

Dr. R. H. Faunce of Sandwich, Mass., died of apoplexy on May 25, at the age of 49 years. He was a graduate of Harvard Medical School in the class of 1882. He was medical examiner for the Cape Cod District. He was a victim of overwork, as it was said of him that only once during the past twenty-three years had he been away from his office overnight.

Dr. R. B. Struthers of Sudbury, Ont., died suddenly May 14, at the age of 50 years. He was a graduate in medicine of McGill University in 1888.

Dr. Oliver J. Beach of Granby, Conn., died May 15 of tuberculosis, at the age of 35 years. He was a graduate of Jefferson Medical College, Philadelphia, in the class of 1900.

Dr. Charles Carrington of Farmington, Conn., died on May 20, at the age of 69 years. He was a graduate of the College of Physicians and Surgeons, New York City, in the class of 1860.

Correspondence.

GRAPHIC EXPRESSION OF THE PHYSICAL STATE.

To the Editor of The Medical Record:

Sir:—I write to ask if it is possible to express numerically the physical condition of a child under one year of age. My reason in doing so is to determine the feasibility of a chart on which the physical progress of babies brought to milk depots which the New York Milk Committee intends to open June 15 may be graphically expressed. This chart, like a weight chart, would be divided horizontally into weeks and days but would run vertically from zero or death to 100 or perfect health. A baby brought to the depot in a dangerous condition would be placed close to the bottom of the chart, near death. If it improved ever so slightly the line would rise and the mother, taking courage, would renew her efforts in its behalf. On the other hand a sudden drop of the line from good, fair, or perfect would alarm the mother who would thus see, if the fault was one of improper care or feeding, how important was her duty to her child.

I can see no reason why conditions capable of comparison cannot be more accurately expressed by numbers than by words. This fact is recognized when, instead of saying "a pulse is high," "a temperature low," "a man is heavy," or "an arm is long," we express these degrees in figures, thus conveying to hundredths and even thousandths the precise idea in our minds. "Perfect," "splendid," "good," "fair," "poor," "bad," "dangerous," "hopeless," as applied to health are all terms of comparison just as are "high," "low," "heavy," "long" as compared to pulse, temperature, weight, and length. Yet who is able to say absolutely what is meant by "fair health" or "good health," by "bad health" or "very poor health?" The answers to these questions necessarily are lengthy and involved; and they rarely suggest the same thing to different individuals.

I should be greatly interested in knowing whether an infant's score card could not be devised which, by a careful and scientific analysis, arranged in such detail as to minimize the possibility of wrong judgment, would give mothers some definite idea of the position occupied by their babies on the scale ranging from death to perfect health.

Wilbur C. Phillips,
Secretary N. Y. Milk Com. of the New York Association for Improving the Condition of the Poor.

EARLY USE OF TUBERCULIN BY THE NON-FEBRILE METHOD.

To the Editor of the Medical Record:

Sir:—Nearly seventeen years ago I returned from Berlin impressed with the definite value of tuberculin as a curative agent, at the same time satisfied that some error must exist in the method of administration to account for its destructive results in many instances.

Experiments were begun at Alicia Hospital, St. Augustine, January 27, 1891, a few weeks after the announcement of Koch's discovery, and these were reported in the Medical Record on October 17 of the same year. The following conclusions were announced: (1) The dose of tuberculin is a widely varying quantity, to be determined, with its rate of increase for each case, only by direct experiment. (2) The only therapeutic dose is such a quantity as arouses no reactive temperature, every reactive fever being the expression of an overdose, that is, a poisonous dose. (3) Tuberculin, when successful by fever reactive method, is so despite, not by virtue of, reactions. (4) Tuberculin by non-reactive method acts as a powerful upbuilding alterative to the tuberculous subject. (5) Patients in all stages of tuberculosis may be treated by nonreactive method without danger.

Under the title "Radical Change in the Application of Koch's Lymph Attended by Marked Success, Fever Reactions Prevented," I detailed the effects of tuberculin, freed from the results of purposely induced fevers. These experiments may have been the first conducted with a definite plan to employ such dosage as, though rising, would avoid fever reactions. Successful treatment at that time was inaugurated on the only lines which have finally found favor among expert workers, whose conclusions, converging from the paths of bacteriology and clinical study, are now universally accepted. The employment of tuberculin in some of its forms, under safe dosage, guarded by clinical evidence, as originally practised by myself, has in recent years been advocated by Trudeau; guarded by observation of the opsonic index, it has proved of value in the hands of Wright and his pupils.

I quote from the above mentioned article: "Observation of numerous cases in Berlin, and especially a study of those in the wards of Leyden at the Charité, to which free access was granted me at all hours, led me to conclude, first, that when treated with tuberculin some cases, though in proportion few, made a definite and continued improvement in general physical conditions, in character of cough, and amount of expectoration; second, that weak men and nearly all women progressed unfavorably. Those cases which ultimately gained lost weight during the first week or two weeks of treatment. Such cases were usually men of great native vigor. Of women, who are especially susceptible to tuberculin-induced fevers, among fifty cases but one was improving in the wards of Senator, nearly the whole number were rapidly fading away, their reactive fevers tending to become continuous as treatment progressed. At Friedrichshain the one hundred charts examined showed that no women with pulmonary forms were improving. Similar results were obtained in the wards of Gerhardt and von Bergmann, and at Moabit Hospital the successful cases shown were men. Among all these cases earlier stages of the disease were numerically well represented, but the induced fevers were exhausting and ruinous to all alike. Of the disturbing or dangerous effects upon the local lesion, I spoke in my Berlin communication to the Medical Record of January 3. Although small doses have been mentioned by various writers, they have been employed with the full purpose of obtaining fever reactions, and have been increased until these were achieved. American observers who have been unsuccessful and have discontinued the treatment have invariably stated that characteristic reactions were obtained. The entire absence of uniformity in results with incipient cases in the hands of all operators, and the uncertainty manifested by all as to the class among incipient cases in which success might be expected, suggested a possible error, not in the constitution of the remedy, but in its method of administration, which hitherto has not been adapted to obtain the fullest therapeutic effects with the least expenditure of energy. To produce every second day the ultra-physiological action of tuberculin, as exhibited in fever reactions, disturbs the general equilibrium and disarranges nervous, digestive, and secretory functions, upon whose very quietude and uninterrupted activity substantial improvement is of necessity based. To employ any medicinal agent on a plan so irrational as that on which Koch's lymph has been used would condemn our most powerful and valuable drugs, and, as in the case of tuberculin, soon discourage both patient and physician. Since the proportion of improved cases in foreign and American hospitals was too small, the risk of the venture under the usual methods too great, I determined at the commencement of experiments at Alicia Hospital, St. Augustine, on January 27, to adopt a plan, not as I am aware until the present time suggested by any observer; namely, to maintain the doses of tuberculin

uniformly below the fever reaction line, proposing to employ such increasing dosage as may be borne by each individual without fever, its pain, mental depression, loss of appetite, and wasting of flesh; thus, perhaps, to escape renewed congestions in the diseased lung areas, and especially to retain general conditions for the patient as favorable, at least, as previous to treatment. Results of this plan are shown in the following notes of all cases treated at Alicia Hospital, taken from the records of this institution. Incipient and advanced cases have been treated. I have endeavored in every instance, although gradually increasing the dose, to retain normal temperature. Women and delicate men in any stage are especially susceptible to the tuberculin fevers, hence the dose has been adapted to their condition. Individuals in apparently the same stage and physical state vary greatly in their resistance to induced fevers. The decided influence which this remedy has exerted in my hands under the gentle, steady pressure of nonreactive doses, has been analogous to that of the iodides—an alterative of well-established power."

FOREIGN BODY IN THE URETHRA.

To the Editor of the Medical Record:

Sir:—Apropos of a recent article in your journal of impaction of a catheter in urethra, I beg to report another case in which a piece of rubber catheter was retained in the urethra, having broken off about two inches from meatus. The catheter, on account of large size, was thoroughly wedged in the canal and could not be manipulated one way or the other. The tip was in the perineum, but could not be moved by pressure in rectum; after a while I succeeded in grasping the end in the anterior urethra, but the catheter was thoroughly rotten and the end broke off in the bite of the forceps. While debating what would be the next move to accomplish its removal I asked the patient if he had urinated since its impaction. He answered in the negative. I then asked him to see if it was possible. After a few minutes' trial, to the relief of myself and patient the catheter was forcibly ejected from the urethra with the stream of urine. The patient, who was about fifty years of age, said he had passed the catheter on account of enlarged prostate and had frequently done the same before. Including half an inch broken off by the forceps, the original length of the piece of catheter was about 5½ inches.

ROYAL SOCIETY'S CONVERSAZIONE—CANCER RESEARCH—INFLUENCE OF PREGNANCY ON DISEASES—SURGICAL VIEW OF ADVANCES IN SYPHILIS—CURIOUS MYOMATOUS UTERUS—DEFENCE OF RESEARCH—OBITUARY.

London, May 15, 1908.

The Annual Conversazione of the Royal Society was held on Wednesday evening. The exhibits were as numerous and interesting as usual, illustrating the results of the year's scientific researches. Not a few appeal mostly to the pure scientist, though others have an interest for the educated public. First from a medical point of view must be reckoned the collection of the Imperial Cancer Research Fund. A series of drawings, microphotographs, and specimens illustrated the experimental study of cancer in animals which has been specially pursued by the fund during the year, and affords evidence that the course of the disease in animals is parallel to that in man. The identity in character of cancer in the skin was shown by specimens from man, bird, frog, and fish. There were fifty-two items devoted to showing in the mouse the lesions characterizing cancer in man. There were records of excisions of cancerous tumors in mice showing that there may be no recurrence for the remainder of the life of the animals. But other records were also given showing that this event is exceptional and recurrence the general rule. But research seems now to have proved that spontaneous disappearance of cancer in animals may take place. Evidence of this was exhibited as to both primary and secondary growths. Charts of a series of experiments illustrated the development of secondary growths and the possibility of preventing that development, raising the hope that we may soon be able to secure patients against the recurrence. Some of the data obtained from hospitals at home and abroad have been set out in tabular form. Photographs of savages suffering from cancer showed the disease in races remote from the influences of civilization.

Another striking exhibit was a display of 100 different types of the plumage of grouse, the object being to establish types of these birds in order to discover whether one is more liable to "grouse disease" than another. Other exhibits afforded abundant material for comment, did space permit.

The influence of pregnancy on various diseases and of these diseases on pregnancy constituted the subject of the Goulstonian Lectures this year, which were delivered by Dr. Herbert French. As a question which has been much discussed, I take the influence of appendicitis on pregnancy and vice versa as an illustration of the lecturer's views. He considers it would be an excellent subject for collective investigation, as that would take in the milder as well as the more severe cases, whereas at present the most striking ones are reported while the milder ones remain in the background. Consequently the severity of appendicitis during pregnancy may be exaggerated. Nevertheless, those who have seen most of the complication regard it as increasing the danger. It may occur at any period of the pregnancy and may be of all degrees of severity, from transient appendicular colic to acute fulminating attacks, rapidly fatal. In mild, early attacks complete subsidence may occur, but owing to increased blood supply and the congestion of the parts due to pressure of the enlarging uterus an unusually rapid course is general, which, if the pregnancy is advanced, will be likely to go on to suppuration. The danger to the mother does not cease with the opening of the abscess, for even after drainage septic salpingitis or endometritis may come on with liability to extension. When pus forms in the later months a miscarriage is almost certain, whether any operation be performed or not, and even when pus is not proved to have formed a similar result is common. This is not surprising, considering that the uterus is almost sure to be in contact with the inflamed tissues and may even form part of the wall of an abscess. It would therefore appear that operation should be accelerated rather than postponed in these cases. There are, of course, mild cases in which it may be better to wait. But those in the next degree of severity, where in the absence of pregnancy waiting might be advised, should be operated on. The prospect of the child is so poor that the interest of the mother only should be considered and spontaneous miscarriage or premature labor is so likely to take place and with it the rending open of the previously localized inflammation and spread to the general peritoneal cavity that it is dangerous to delay. Further, it is to the last degree undesirable that obstetric measures for terminating the pregnancy should be resorted to for fear of breaking down adhesions that are helping to localize the appendicitis. At the same time it may be said that in case of appendicitis of any severity in a pregnant woman the best chance of saving both mother and child is in early operation.

The Medical Society of London, which, as you know, declined to join in the amalgamation and so become a section in the Royal Society of Medicine, continues its career much as previously. There are a few of the Fellows who rather regret the decision and are ready to reconsider it, but, considering all the circumstances, it is doubtful if the majority are prepared for any change. As the oldest society and one that was a general favorite, its prestige is great. That it still commands excellent papers is obvious enough, and there seems room for its work as well as that of one or two others that continue an independent course.

On Monday, Mr. D'Arcy Power gave us a paper on "Recent Advances in the Surgical Knowledge and Treatment of Syphilis." He pointed out that advances in physics, such as the discovery of the Roentgen rays, had proved of great value in the diagnosis and treatment of bone and joint cases. Then histology has enabled us to classify cases of white swelling as tuberculosis or gummatous. The modern view seems to be that in some cases a gummatous synovotis is really a tuberculous inflammation infecting the joint in a subject of inherited syphilis. It is now necessary to recognize intermediate cases due to microbic infection of tissues which have been modified by the spirochæta pallida, whether acquired or inherited. Pneumococcus and staphylococcus also invade such tissues, and influenza may set up arthritis which has a gummatous character in these patients. The *x*-rays help us distinguish osteitis and arthritis due to syphilis from analogous lesions produced by tubercle or rheumatism. The rays have also taught us that syphilitic inflammation of bones may begin much later than had been supposed.

The advances in treatment have been, firstly, a firm belief in the power of mercury, when properly administered, to cure the disease, not merely disguise symptoms. Secondly, a clear understanding of the use of iodides. The tissues cannot rid themselves of large masses of syphilitic products, and it is best, therefore, to remove them by surgery and not expect them to be absorbed. Iodides may then be given with good results, but should always be followed by a mercurial course.

At the Irish Academy last month Sir W. Smyly showed a myomatous uterus, the interest of it being entirely technical. On examining the patient he could not reach the cervix owing to the extraperitoneal development of the tumor on the right side of the uterus. On operating he took the end of the tumor to be the cervix; there was a depression in it which he took for the os. When he cut into the capsule there came a good deal of blood, which surprised him. When he got it open enough he found he was in the capsule of the tumor and had not opened the vagina at all. He completed the operation—Doyen's—in the usual way. The tumor was in the long axis of the uterus, and there was little wonder he mistook it. Sir A. V. Macan said he was present at the operation and corroborated the difficulty of locating the cervix. Prof. Alfred Smith approved the procedure. With these eminent leaders thus deceived by the unusual conditions, less experienced men may be glad not to have had such a case.

The foundation of the Research Defense Society has produced a panic among the antivivisectionists. That may be a favorable augury. On Tuesday a demonstration was got up against the new society. Sir George Kekewich, M.P., took the chair, and his speech will scarcely add to his reputation. He declared that "vivisection was a horrible and degrading cult, a pseudo-science which the doctors reveled in because they had got inured to that kind of cruelty." Sir George poses as an educationist, and set this example of free speech. I commend to his study the seven abominations enumerated in the sixth chapter of Proverbs.

Dr. C. J. Cullingworth, Consulting Obstetric Physician, St. Thomas' Hospital, died on the 11th inst. in his 67th year. A Leeds student, he qualified in 1865-6. In 1878 he became a member of the London College of Physicians and was elected a Fellow in 1887. Meantime he had taken M.D., Durham, 1881, and in 1893 that university conferred on him the honorary D.C.L. He had been Professor of Obstetrics and Gynecology at Manchester, Physician to St. Mary's Hospital there, and Examiner in the University. He came to London about twenty years ago as Obstetric Physician to St. Thomas' Hospital. Here he was soon recognized as a consultant to be trusted, and his death will be regretted both here and in Manchester. He contributed careful papers to the Hospital Reports as well as other journals. He also contributed to Allbutt & Playfair's "System of Gynecology."

The death occurred on Thursday, the 7th inst., of J. A. Balmanno Squire, at the age of 71. He was for many years Surgeon to the British Hospital for Skin Diseases and had lectured on the specialty at St. Mary's Hospital and written much upon it. He was a university college student and took the London M.B. with the gold medal in 1862. He wrote the article on "Diseases of the Skin" in Reynold's "System of Medicine" and contributed extensively to the journals and societies. You will, no doubt, remember his "Atlas of Colored Photographs" of Skin diseases. His "Manual of Diseases of the Skin" was also a successful work.

Dr. Gramshaw, of York, died on the 7th inst., aged 54. The day before he was found unconscious in his room from the effects of morphia, which he seems to have injected himself. He became partially conscious, but afterwards collapsed, apparently from pulmonary complication. He qualified in 1878, took M. D. Stand. 1896, and F.R.C.S., Eng., in 1903. He first qualified in Pennsylvania and came to England afterwards and took British diplomas.

OUR PARIS LETTER.

(From Our Special Correspondent.)

CALCULI OF THE URETER—URETERAL ANASTOMOSIS—RADIOGRAPHY OF THE STOMACH—THE TREATMENT OF NEVI.

PARIS, May 1, 1908.

An interesting discussion on the subject of ureteral calculi was held at a recent meeting of the Société de Chirurgie. Rochard began by pointing out the errors that might arise from the use of radiography in such cases. He had caused a radiograph to be made in the case of a woman of sixty-seven, suffering from an arthritis of the hip. The picture showed obliquity of the pelvis and a deformity of the large trochanter, but there was also to be seen a linear shadow at the brim of the pelvis on the left side, which was ascribed to a calculus in the ureter. Vaginal examination and abdominal palpation were negative, while catheterization of the ureter performed by Luys demonstrated that this structure was entirely free from any obstruction throughout its entire length. The shadow on the radiographic plate, therefore, could not be due to a stone and was probably caused by the atheromatous condition of the iliac artery. A radiograph of the arms showed that the brachial artery was plainly visible, thus proving that the supposition was true.

Following this paper Georges Luys reported several observations, showing that, while the radiograph sometimes appears to show ureteral stones which do not exist, on the other hand, actual calculi may not appear on the negative. A man of thirty-nine years, who for about nine years had suffered from attacks of renal colic, sometimes on the right, sometimes on the left side, was subjected to catheterization of the left ureter after a particularly severe seizure of pain on this side, lasting several hours. In performing the operation Luys was able to distinguish very clearly a grating contact of the ureteral bougie which indicated the presence of a stone in this tube. The patient was then sent to a radiographer, who reported that there was no evidence of the presence of any stone in the ureter. Four days later, after an exceedingly painful attack, the patient passed two stones, as large as beans. The patient was seen several days later and the left ureter was again catheterized, but with negative result. The stones were then examined with the fluoroscope and were distinctly seen. The failure to perceive them on the photographic plate was therefore not due to their chemical composition.

Lucien Picqué then reported a case in which a patient had been radiographed after a series of attacks of renal colic. The negatives showed the presence of concretions apparently, in the ureter. Laparotomy was done twice, first on the right side, then on the left, but no stones were found.

Prof. Pozzi then described an interesting operation on a woman having a ureteral calculus which was removed by extraperitoneal laparotomy. For more than six years the patient had suffered from pain in the right iliac fossa, radiating to the lumbar region of the same side and coming on in acute spasms. By vaginal examination and by means of the Roentgen rays the diagnosis of a stone in the right ureter was made. Pozzi then invited Luys to examine the patient. With his direct vision cystoscope the latter catheterized the right ureter and found that the ureteral bougie was stopped 2 cm. from the mouth of the ureter. Progressive dilatation of the ureter was practised with instruments of increasing sizes and in this way it was possible to obtain distinct contact with the stone. Then two laminaria tents were introduced and kept in position for twenty-four hours each. The attempt was then made to remove the stone by means of delicate forceps, but this was unsuccessful, and as it was evident that the stone was impacted, a bloody operation was decided on. This Pozzi effected by a lateral extraperitoneal laparotomy. The ureter was exposed and incised over the stone, but the removal of the concretion was difficult owing to the fact that it was very adherent to the interior of the ureter. A month later the patient left her bed completely cured. Luys then made an examination by means of his urinary separator in order to determine the functional efficiency of the right kidney. It was seen that the amount of urine secreted by the right kidney was now double that of the left side. Whereas, before the operation only one-half c.c. was passed in from thirty-five to forty-five minutes, the amount was now 17 c.c. The secretion from the kidney of the left side remained the same as before. The kidney on the side operated on was therefore stimulated to increased activity as the result of the operation.

At the same session of the society, Prof. Pozzi also presented an interesting case, showing the excellent functional result of a ureteral anastomosis done twenty-one months before. The patient was a woman who was subjected to complete abdominal hysterectomy for a very adherent pyosalpinx. In the course of the operation the right ureter was cut, but was at once repaired by end-to-end anastomosis. The patient recovered completely, and the good result of the operation was proved by separation of the urine performed by Luys twenty-one months later.

Leven and Barrett before the Société Médicale des Hôpitaux read a paper in which they showed that Roentgen ray examination of the stomach often enabled the diagnosis of carcinoma to be made when there was no other evidence of the condition, or to eliminate this possibility when its presence was suspected. This assertion has been proved both by autopsies and surgical operations. They described the case of a patient who gained three kilograms in weight in three weeks and had no stomach symptoms, but in whom radioscopic examination suggested the diagnosis of carcinoma, which was verified at an autopsy two months later.

Masotti has described the treatment of nevi by means of radium. He commenced by trying on himself the apparatus which he subsequently used on his patients, and ascertained that in applying radium for therapeutic purposes it is necessary to take into consideration the pressure exerted by the apparatus used, the initial activity of the radium, its weight, the manner in which it is diluted, the date of its manufacture, the thickness of the screens, the temperature, and the moisture of the air. He then showed plaster casts showing the condition of the lesions before the treatment. It was seen that this had produced a remarkable improvement, the pigmentation of the skin being greatly reduced, while the scars were perfectly satisfactory from the cosmetic standpoint. Masotti also described a new plan of treatment for various pigmentations of the skin, such as chloasma, by means of scarification and the application of peroxide of hydrogen. At intervals of five days the lesion is scarified by means of shallow and very numerous incisions, and is then washed with peroxide of hydrogen. The next day an erythema appears, which several days later is followed by moderate desquamation. Three or four treatments usually cause complete disappearance of the spot. The result is due to a double action. The scarification incites a prompt renewal of the epidermis, while the peroxide of hydrogen is enabled to come into direct contact with the tissues and so decolorizes the pigment directly.

OUR BERLIN LETTER.

(From Our Special Correspondent.)

SERUM DIAGNOSIS OF SYPHILIS—MEDICAL STUDY IN GERMANY —INFLUENZA IN BERLIN—QUACKERY IN GERMANY.

BERLIN, April 25, 1908.

AN interesting debate on the serum diagnosis of syphilis has been held by the Medical Society. Although there is danger that the reader may be wearied by the frequent discussion of the subject, what was said on this occasion deserves mention because a number of eminent observers took part. The theory and practice of serum diagnosis of syphilis was discussed by Fleischmann. He had found that the active substance obtained from syphilitic livers was soluble in alcohol and that the chief agent in the reaction was combined with lecithin. Alcoholic extracts of such livers could be used for the fixation experiments as well as the salt solution extracts ordinarily employed. If a lecithin emulsion was used instead of the liver extract, fixation would be obtained, but it was much weaker. Cholesterin and vaselin also caused fixation of the complement with luetic serum to a rather greater extent than lecithin. Nonluetic human sera do not react with these lipoid substances, but rabbit serum does. Nine hundred control cases have been described in the literature, and only six gave a positive reaction. Of 160 cases examined 73 per cent. were positive. Concerning the details of the examination a few practical points might be mentioned. If the reaction is positive, specific treatment should be begun. Absence of the reaction does not indicate a cure. Of eighteen tabetics, of whom sixteen had a history of syphilis, only thirteen showed fixation of the complement. The most pronounced reaction is to be found in cases in which no specific treatment has been employed. The method is especially useful in cases with a doubtful history, and if the reaction is positive syphilis is surely present. On the other hand, if it is negative the disease cannot be excluded with certainty.

Blaschko followed with a paper on the same subject. He had set out to determine whether a positive reaction indicated that the patient was or had been diseased. In order to ascertain what became of the syphilitics, a search was made through the records of the large life insurance companies. It was found that one-third of the syphilitics die of the consequences of the disease. The mortality records show that the proportion of syphilitics to non-syphilitics in cases of disease of the spinal cord is as 667:100, in paralysis 500:100, in psychoses 145:100, in apoplexy 228:100, in renal diseases 164:100, in circulatory disorders 200:100. The result of the reaction indicates nothing concerning the severity of the infection, for a positive test may be obtained in mild cases and a negative result in severe ones.

Citron spoke of the significance of modern syphilis investigations. As the result of his experience he advised beginning specific treatment in the first stage if the reaction was positive. Furthermore, later on, whenever the reaction was positive, a new course of treatment should be begun.

In the discussion Sachs and Altmann, from Ehrlich's Institute in Frankfort, stated that of all the methods, those originally described by Wassermann had remained the most satisfactory. This observer continued of the opinion that reliable results were to be obtained only by means of the method of fixation of the complement, for it alone had never given positive results when syphilis was not present. Neisser of Breslau described the results obtained by Bruck on a large number of monkeys in Java. The lower monkeys normally possessed antibodies against syphilis, which are absent in the higher apes. On infection these appear before the development of the primary lesion. The demonstration of the antigen is very difficult, but may be facilitated by heating the organs to 55°. The quantity of antigen does not correspond to the course of the disease, and it could be demonstrated in animals that were infected without result. His attempts to devise a cutaneous or conjunctival reaction in man had been unsuccessful. Karewsky described surgical cases, particularly those of bone syphilis, in which the method of fixation of the complement had been found very useful from the diagnostic standpoint. Proskauer had found the procedure serviceable after death in certain cases in order to clear up the diagnosis. Ledermann assumed that the reaction would be positive for only about five years in cases which had been well treated. It was going too far to base consent for marriage on the result of the reaction. Mühsam had shown that in cases that had been treated with mercury the reaction could be less frequently obtained than when potassium iodide was used.

For a while it seemed as if, thanks to the dissemination of knowledge concerning the incomes of medical men, the number of medical students in Germany had begun to decrease. The latest figures show, however, that the increase in the number of students and of physicians is constant. In the summer session of 1907, there were 7,574 medical students in Germany, while in the year 1906 there were only 6,570. The number of physicians during the same period has increased from 30,931 to 31,416. In Berlin there are for every ten thousand inhabitants 11.7 physicians; in the other large cities there are 9.5; in cities with a population between ten and fifty thousand, 7, and in communities of less than ten thousand inhabitants, 2.9. The largest proportion is in Wiesbaden, where there are 25.4 physicians per ten thousand inhabitants. Munich comes next with 15.9, Frankfort with 12.1, Stuttgart with 10.4, Cologne 9.6, and Hamburg 7.7. The number of specialists is very large in the more important cities. In Dresden it is 44.6 per cent.; in Frankfort 43.2 per cent., and in Munich 38.7 per cent. of the total number of medical men.

During January and February, the physicians of Berlin were busily employed, for influenza with its sequelæ was unusually widespread during this period. How little the incomes of Berlin physicians fluctuate, however, is shown by the recently published figures of the Aerztekammer. According to these in the year 1907 20.4 per cent. of the physicians still had an income of less than 3,000 marks, and 41.4 per cent. of less than 5,000 marks.

Quackery is widespread throughout the entire world, but there are districts in Germany, particularly in Saxony, which are hard to equal in their number of illegal practitioners. The increase in this pest took its origin when general freedom of occupation was made legal in Germany. Since that time every one who felt himself inclined was permitted to practise the healing art, while the physician was allowed to do this only after the authorities had investigated his qualifications. For years the German physicians have attempted to induce the government to restrict this freedom of the right to treat disease. Recently a preliminary plan of legislation has been made public by the government, which does not meet the wishes of the medical profession, but includes a number of restrictions capable of abolishing the most serious abuses. According to this,

every one who intends to engage in the treatment of disease must register with the authorities. He is compelled to maintain an accurate system of bookkeeping, and treatment by letter is forbidden. This occupation is prohibited to all of those who have been convicted of any offense, as well as to those who are likely to prove dangerous to the life or health of their patients. Venereal diseases cannot be treated at all, and preparations for their cure or for the prevention of conception must not be advertised. Other remedies which might lead to damage to the health or involve deception of the users may be prohibited on the advice of a commission founded for this purpose, and the composition of all remedies must in all cases be exactly indicated. In the year 1903 the number of nonregistered practitioners in Germany was estimated as 10,000. From 1888 to 1901 1,724,000 books having a value of fourteen and a half millions of marks, written by persons of this type, were sold. A single quack has disposed of more than a million copies of his book. Over 50,000 periodicals are circulated. One quack for a time had over 800 patients daily who paid three marks per consultation.

THE GERMAN SURGICAL CONGRESS.

(From Our Special Correspondent.)

(*Concluded from page 912.*)

HERNIA—SURGICAL ANATOMY OF THE GALL-DUCTS—PATHOLOGY OF GALLSTONES — PROSTATECTOMY — FETAL PERITONITIS — RENAL CALCULI—SUTURE IN URETHRAL TEARS—PROGNOSIS OF DISLOCATION—BLOODY REDUCTION OF OLD DISLOCATION OF THE ELBOW—COXA VALGA—EXPERIMENTAL JOINT-MICE—AMBULATORY TREATMENT OF FRACTURES OF THE UPPER EXTREMITY.

VIENNA, May 9, 1908

THE fourth day of the meeting of the German Surgical Association was opened with a paper by Schlosser of Innsbruck on "Chronic Inflammatory Tumors After Operations for Hernia." It has been noticed that after operations for hernia, with primary healing of the operation wound, a painless swelling unaccompanied with fever appeared in some cases in the right lower abdominal region. Operations in such cases showed the presence of connective tissue with occasional suppurative foci. As in all cases observed up to the present time silk was used in the primary operation, these "tumors" could be explained by the inflammatory processes going on in the tissues and having for their aim the discharge of the offending foreign body. Treatment of this condition should consist of antiphlogistic measures, and the evacuation of pus in the cases where it makes its appearance.

Brenner of Linz presented his "Method of Operation in Umbilical Hernia with the Use of Double Flaps." His procedure consists in freeing the inner portion of the aponeurosis of the recti muscles so that on each side of the umbilical ring a crescentic flap of aponeurotic tissue is present. The free edge of each of these flaps is then pulled over to the other side and is sewn on to the edge of the rectus muscle of that side. In this manner the hernial opening is closed by a double fold of connective tissue.

Ruge of Berlin spoke of "The Surgical Anatomy of the Gall-ducts." In the anatomical examination of the gall-ducts the author of the paper has discovered abnormalities in the course of the cystic and the hepatic ducts, which were very important from the standpoint of practical surgery. Of the forty-three cases examined only in fourteen was there found the acute angled junction of the cystic and hepatic duct which is usually described as typical. In nine cases the cystic duct was found to be firmly united to the hepatic duct for a considerable portion of its course. If in such a case the attempt is made to pass a sound through the hepatic duct by way of the cystic duct, the latter must be opened for the whole length of its course before the mouth of the hepatic duct is discovered. In sixteen cases the cystic duct ran as a sling about the hepatic duct and only then opened into the latter. In such a case pulling upon the cystic duct obliterated the lumen of the hepatic duct, thus simulating a stenosis of the latter.

Exner and Hejrovsky of Vienna spoke on "The Pathology of Gallstones." They added salts of the bile acids to the bouillon cultures and then inoculated the cultures with various bacteria. It appeared that the typhoid and the colon bacilli decomposed these salts. Such decomposition would lead to the precipitation of cholesterin, which is held in solution by the presence of the salts. Partial precipitation of the salts could lead to the precipitation of some cholesterin, likewise, thus giving rise to the formation of gallstones.

Wilms of Basel read a paper on "The Technique of Prostatectomy" and recommended a useful modification of the usual technique. The skin is incised close to the ascending ramus of the pubic bone. The loose fatty tissue is pushed out of the way and the prostate appears immediately in sight. It is then shelled out by dull dissection, this procedure taking no more time than the removal of the prostate by the suprapubic route. In addition to the rapidity of the operation it possesses the further advantage that the rectum does not come into the operative field. In the discussion that followed this paper Ehrhardt of Königsberg spoke on the operative treatment of carcinoma of the prostate. He said that up to the present time it has been assumed that a very rapid appearance of metastases takes place in the carcinoma of the prostate, and this assumption made the surgeons quite unwilling to operate in most cases of this disease. The speaker believes that operations in such cases should be more frequently performed. His operative technique consists of making very large T-shaped incision through the skin of the perineum reaching up to the scrotum.

Peiser of Breslau read a paper on "Fetal Peritonitis." He said that the diagnosis of fetal peritonitis cannot be finally made. The possibility must enter the surgeon's mind when symptoms of intestinal obstruction appear in the newborn or in older children. As such peritonitis makes itself evident in localized places only, therapeutic interference is possible. Up to the present time only one case has been observed by the speaker in which masses of fibrous bands were found in the abdomen and yet the patient recovered. All other cases observed by the author or described in literature ended fatally.

The next paper was on "The Diagnosis of and Operation for Stones of the Kidney" by Zuckerkandl of Vienna. He distinguished between encapsulated and free stones of the kidney, and said that the favorite spot for their location is the junction of the renal pelvis with the ureter. The encapsulated stones show upon the *x*-ray plate furrows made by the kidney calices, or they give an uneven shadow directed downward. The free stones give round shadows upon the plates; these stones usually lie in cavities which have been formed in the substance of the kidney. A ureter sound filled with bismuth gives on the picture the place where it strikes the stone. As far as treatment is concerned, the speaker expressed himself against nephrotomy because in such cases a great deal of necrosis takes place and large portions of the kidney are lost. In place of nephrotomy, therefore, in most cases of stones of the kidney pyelotomy ought to be done. The operative wound of the kidney pelvis is drained for fourteen days. Of seventeen patients operated upon in this manner sixteen recovered without the formation of fistula.

Pels-Leusden of Berlin then considered the necessity of a circular suture in cases of tears of the urethra near the perineum. The speaker thinks that such suture is not always necessary and simple junction of the stumps by means of a few sutures is sufficient. The latter procedure is improved by splitting the stumps a little in the longitudinal direction, which produces surfaces that are easily united by three or four sutures. Experiments on dogs have shown that a canal is formed in such cases without the formation of fistula. A permanent catheter is not considered necessary by the author. The technique of the operation is given completely in the textbook of Koenig.

In the afternoon Küttner of Breslau read a paper on "The Prognosis of Traumatic Dislocations." Of 160 cases of fresh dislocations 54 simple uncomplicated cases were followed for many years; 63 per cent. of the patients were over 50 years old. Only seven of the 54 showed complete recovery from the injury, while 14 showed loss of power in the extremity. All the others showed considerable interference with the motions of the extremities, suffered some pain, and lost much power in using the affected parts. The conclusion is, therefore, that two-thirds of the recent uncomplicated injuries of this character, though treated in the best accepted manner, showed unsatisfactory results. The after-treatment in all these cases was thoroughly carried out.

Dolliger of Budapest then discussed "The Bloody Reduction of Old Dislocations of the Elbow." He had treated thirty-four old cases of such injury. In all of them arthrotomy was done and then the conclusion was reached in reference to the treatment of the given case, the advisability of reduction or of resection being considered each time. In fourteen cases resection was

performed, nine of them healed by primary union; in six cases the joints remained stiff, in four their motions were limited, in one case complete recovery ensued. In twenty cases reduction was performed, being preceded by an incision on the outer side of the joint. In twelve patients useful joints resulted from this procedure. Three patients remained with stiff joints, and of the rest, nine had movable joints. Of the latter only three showed complete range of motion, though the rest commanded quite a range of movement. Accordingly the possibility of the reduction of the bones is to be thought of in every such case.

Stieda of Königsberg spoke on "Coxa Valga of Adults," two cases of which he has observed. In such cases, when the patient is lying on his back, outward rotation is observed and flexion is limited. In walking, the limb is held fairly stiff. The *x*-ray picture shows great increase in the angle of the neck of the femur, and the small trochanter is very prominent. The latter appearance is caused by the fact that the femur has rotated forward, thus bringing the trochanter forward with it. The treatment consisted in sparing the limb, proper exercise, and massage. The results were satisfactory.

Becker of Rostock read a paper on "Experimental Joint Mouse." He detached a small piece of the epicondyle in the joint of the dog; months afterward the presence of a joint mouse in that joint was established, this being the first successful case of producing this condition by experiment. In all other attempts the piece of detached tissue either disappeared or became attached somewhere in the joint.

"Ambulatory and Extension Treatment of Fracture of the Upper Extremity" was the subject of the next paper by Borchgrevink of Christiana. He used apparatus in which traction was made by means of rubber tubes. The splint for the upper arm contained a fork-like attachment which fitted into the axilla and gave the point of support for traction. The splint for use in the affections of the forearm contained a perpendicular piece which was fastened to the upper arm and thus gave a firm point for the traction exercised upon the forearm. These splints were used in the practice of the author for ten years and the results were better than in the case of all other apparatus and methods of treatment.

Progress of Medical Science.

Boston Medical and Surgical Journal, May 21, 1908.

Varicose Veins of the Papilla of the Kidney a Cause for Persistent Hematuria.—W. F. Whitney reports the case of a middle-aged man with a history of repeated attacks of hematuria lasting over a considerable period of time. Examination by modern methods as well as in the usual clinical way revealed no cause for the trouble until finally bloody urine was observed coming from one ureter. The corresponding kidney was removed. It appeared pale but otherwise normal. The tips of one or two of the papillæ were a little reddened and under the microscope these tips showed the small veins, dilated irregularly to twice or three times their normal size, and covered on their free surface with the finest possible film of connective tissue and a single layer of epithelial cells. Here and there they projected as varicose knuckles above the surface. The conditions, in fact, were such that the slightest violence must have caused a rupture with subsequent escape of blood. In one specimen a rent was found in one of these thin-walled channels, but it cannot be stated positively that it may not have been an artefact. The lumen of the vessels, in many places, was filled with a finely granular detritus and occasional blood corpuscles, but no well-marked thrombi were seen. That hemorrhage must have taken place here, however, is borne out by the fact that the straight tubules of this region contained blood corpuscles, which were not found higher than the base of the pyramid. Whitney says that these anatomical conditions are certainly adequate to cause frequent and severe hemorrhage. He gives summarized histories of a group of similar cases reported by Jennick, together with pathological findings. While the entire number of such observations is still small, it will be necessary in the future to exclude a varicose condition of the renal papilla before it can be said that a hematuria is without cause.

Certain Common Disorders Frequently Misinterpreted.—G. L. Walton presents an interesting paper along the line suggested by his title. He notes, among other things, that the term facial neuralgia gives as a rule very little clue to the real nature of the malady. Cases of supraorbital pain with a certain periodicity are called malarial, and quinine is given, but without avail, as the trouble is due to an infection of some accessory nasal sinus. In fact, the diagnosis of facial neuralgia has come to mean very little to the author except in case of elderly people, whose nerves have become degenerated by atheroma, in which case a true nerve pain, tic douloureux, does exist, paroxysmal, severe, and, as a rule, only to be relieved by operation. He is forced to the conclusion that by far the greater number of facial neuralgias in young and middle-aged persons come from the eye, the ear, the nasal cavity, and accessory sinuses, from the teeth, or skeletal disorders, such as necrosis or pressure from periostitis or tumor growth upon the trifacial nerve in its long course through bony orifices and around bony prominences. Another class of disorders is that included under the general name of tic, abnormal facial movements, etc. Dental and ocular irregularities are often at the bottom of such cases. Pain in the shoulder and upper arm with atrophy of the deltoid is often called neuritis. The fact is that the joint is probably at fault. Occupation neuroses, such as writer's cramp, are often regarded only in their local aspect, but the pain complained of may be only the expression of rebellion on the part of exhausted nerve centers. Similarly, sciatica is frequently due to disease of the spinal column at the point of emergence of the nerve-roots, an osteoarthritis, or a sprain of the sacroiliac synchondrosis. Flat foot is another illustration of the author's main proposition, for symptoms are often referred to and confined to other parts, as the knee. The author makes a plea for the independent investigation of each case in place of blind reliance on time-honored diagnoses.

New York Medical Journal, May 23, 1908.

Mucomembranous Enterocolitis; Its Causes and Mechanism.—The two main propositions of H. Nepper are that the false membrane in the malady is the agent which increases coagulative power and diminishes biliary secretion which permits its beneficial function, and that the malady is the result of over biliary secretion. The author enumerates the various causal factors which have been invoked by different authors and discusses the various theories which have been put forth as to its essential pathology. The two main features are fecal stasis and evacuation of mucus. From the author's experiments on dogs, he finds that to be constipated means to have an insufficient biliary secretion, the result of innumerable causes. Suffering from enterocolitis means constipation and evacuation of coagulated mucus—that is, to have an insufficient secretion of bile. Consequently constipation and enterocolitis have the same origin. They are both varieties of the same phenomena, two states of the same affection, enterocolitis differing from constipation only by the addition of a second factor, coagulatory power. The mechanism of enterocolitis and constipation, therefore, seems to be well established. As soon as the liver is overworked on account of whatever cause (and this will happen, especially in patients who easily suffer from oversecretion or arthritis in patients who follow a secondary occupation), biliary secretion will decrease, and, according to the cases, result either in enterocolitis or in constipation. When this becomes later chronic mucomembranous evacuation will take place, possibly complicated by all kinds of infections, either in the liver (angiocholitis, cholecystitis, gallstones, or in the intestines, appendicitis, etc.).

Malnutrition.—M. Korshet discusses the occurrence of malnutrition among the large dispensary clientèle. He finds that the underlying basis of the vast majority of cases of illness is in the last analysis deficiency of food, both in quality and quantity. He says that conditions make the man, and only secondarily does man react on his conditions. Social conditions to-day deny to the laboring classes an opportunity to procure for themselves and their children proper food and surroundings, with the result that malnutrition swiftly enters to disable and kill. Personal hygiene and compulsory medical treatment may correct certain physical defects, but not until faulty social conditions are removed will the basic cause of these defects be eliminated. A change in social conditions will not only assure to the working classes an abundance of good food, fresh air, and sunshine, thus weeding out the ills of malnutrition, but make of the physician a public officer working for the prevention of disease for the general good in place of an individual business man treating disease as a means of private gain. Then, and only then, will the school child, properly fed, clothed, and housed, be in a fit physical and mental condition to absorb what it is taught.

The Rôle of the Sphenopalatine (or Meckel's) Ganglion in Nasal Headaches.—G. Sluder refers to a group of ten cases with headache, irregular as to the time of its appearance, and irregular as to the part of the head

involved. Sometimes it was referred to behind the eyes, sometimes to the upper jaw in front, and sometimes to the hard or soft palate. Occasionally the nose was said to ache in the back, or the teeth were described as sore, or the pain was referred to the temple and to the occiput or neck. This headache appeared most irregularly, but was seldom absent for more than a short time. It sometimes would become severe and behave as a migraine. Sometimes an indefinite sense of stiffness was described. These symptoms appeared from day to day, alternating one with the other, or associated two or three together. Still more recently he has seen some high-grade inflammatory troubles in the posterior ethmoidal and sphenoidal sinuses, which have subsided and healed, usually within a week or two, but have left the train of symptoms, as described, in their wake, and these have continued on more or less indefinitely. This exceedingly irregular train of symptoms cannot be explained on a basis of inflammatory troubles in the accessory sinuses. They seemed to him neuralgic, and to have been excited by the forerunning inflammatory process in the nose. The coal tar products give transitory relief. The author discusses the anatomical relations of Meekel's ganglion, and says that the anesthetization of it relieved some of his patients completely. The anesthetization was carried out by placing a drop of a 20 per cent. cocaine solution over the ganglion—that is, as a rule, just posterior to the posterior tip of the middle turbinate. When the cocaine succeeded in giving relief, the author thought the ganglion was close to the external wall of the nose, and if it failed it probably was deeper. The relief would last for from fifteen minutes to one hour, and occasionally the cocaine would abate the attack. None of the cases observed were of sufficient severity to justify operative intervention. Application of 2 per cent. silver nitrate solution or ½ per cent. formaldehyde to that area of the nose either cured or helped the pain.

Middle-Ear Deafness.—W. S. Bryant reports 24 cases, and claims that all forms of middle-ear deafness except the congenital are amenable to treatment, and that the amount of improvement justifies the effort expended. He says that the amount of possible improvement in hearing is in inverse ratio to the pathological changes. Chronic deafness from past or present suppuration of the middle ear can, without exception, be helped by treatment. The amount of help depends upon the power of the patient to make repair and to substitute parts which have been lost. Deafness following middle-ear catarrh is more resistant. Ninety-eight per cent. of chronic deafness is due in whole or part to middle-ear disease. Chronic middle-ear catarrh makes about 69 per cent. of all chronic deafness, while middle-ear suppuration causes about 13 per cent. of chronic deafness. The causes of chronic middle-ear catarrh arise in the nasopharynx and affect the middle ear by interfering with the Eustachian tube. The aim of treatment is first to restore the functions of the Eustachian tube, and, second, to correct the defects of the middle ear. By treatment of the nasopharynx, prophylaxis of these defects is easily assured. The chief difference between the etiology of middle-ear suppuration and chronic middle-ear catarrh is pyogenic bacterial infection. Suppuration occurs almost never independent of nasopharyngeal disease. Prophylaxis of chronic middle-ear deafness due to suppuration is secured by preventing purulent inflammation through care of the nasopharynx. But if suppuration has already begun the hearing is preserved by immediately stopping the suppuration and by treating the nasopharynx appropriately. If any suppuration should exist in chronic middle-ear deafness it must be immediately arrested. If perforations of the membrane exist they must be closed by the growth of cicatrices. In order to compensate for the important parts of the sound-conducting mechanism which may have been lost, it is necessary to adjust mechanical appliances. Adhesions of important parts must be loosened.

Journal of the American Medical Association, May 23, 1908.

Cancer in the Philippines.—F. W. Dudley disputes the alleged absence or rarity of cancer in tropical countries. It certainly occurs in the Philippines where 301 deaths from this cause were reported in 1902, a figure which Dudley, from his knowledge of the imperfections of the statistics, feels safe in saying could be multiplied by one hundred to represent the real facts, bringing the death rate from this cause up to about 5 per cent. His conclusions are given as follows: "1. Cancer is not confined to temperate climates. 2. It is believed that cancer exists in the Philiopine Islands to a greater extent than in the United States. 3. The measures now being taken in other more enlightened countries to warn the people of the necessity of early diagnosis, and early radical surgical treatment in this disease, should be adopted here. 4. The disease is of sufficient importance in the Philippine Islands to warrant an effort being made to obtain better statistics in the future."

Milk Sickness.—The causes of milk sickness, a disease formerly common in portions of the country but rare at present, are discussed by E. O. Jordan and N. M. Harris, who report the discovery of a new focus of the disease in the valley of the Pecos River, New Mexico. The symptoms are chiefly persistent nausea and vomiting, obstinate constipation, sweetish acetone odor of the breath, muscular weakness, abdominal pain and prostration. There is little or no fever; little is known as to the incubation period and autopsy records are few and unreliable. It is peculiar in its association with certain localities, generally on the banks of streams, and with a disease of cattle, known as "the trembles" or "slows" with a symptomatology suggesting the human disease. There are numerous instances in the literature showing a connection between the use of the meat or milk of cattle sick with "trembles" and the disorder in man. Poisonous herbs generally have been credited with causing the disease in cattle, the white snakeroot, poison ivy, and in New Mexico, the rayless goldenrod (*Bigelovia rusbyi*), but the authors express no opinion on this point. Two cases in the convalescent stage in man were observed by them and they were able to study the progress of the disease in a herd of cattle and to obtain all pertinent data. The chief pathological lesions were found in the liver, heart muscle, kidneys, and small intestine; the changes are those of a parenchymatous nature, such as are frequently produced by toxic action in general; namely, cloudy swelling and fatty metamorphosis. The severest action is shown in the liver tissue. In other organs than those mentioned above, nothing of very particular interest was observed as yet. Bacteriological studies revealed the presence in the tissues and body fluids of infected animals of a bacillus which, grown on agar cultures, showed as a rod a little smaller than the anthrax bacillus, occurring singly and in pairs and in occasional filaments, staining somewhat unevenly with methylene blue, spore-forming, the spores perfectly round and at the end of the rods in mature forms, reminding one of the tetanus bacillus. In immature forms the spores may be slightly oval and lie not quite at the end of the rod. They stain readily with any of the ordinary methods. The organism is motile and Van Ermingen's stain shows ten or fifteen flagella disposed peritrichally: the flagella measuring about five times as long as the bacillus. Full details of cultural appearances and of animal experiments, inoculation and feeding, are given, together with pathological findings. As the inferences from the first fatal results of inoculation of rabbits with the bacillus obtained from the body fluids were supported by the later experiments with pure cultures, the authors have designated the bacillus as *B. lactimorbi*. As a more comprehensive study of the subject is intended the authors will be grateful to any physicians who will notify them at once of the occurrence in any locality of milk sickness or of the cattle disease, "trembles," "slows," or "alkali poisoning."

Synovial Fringes.—After referring to former writings on the subject, E. G. Abbott says that his views have changed somewhat in regard to the value of operative treatment of hypertrophied synovial fringes interfering with motion in the knee joint. In his definition of the condition, he excludes the pathological changes sometimes classed with it—lipoma arborescens, chronic villous arthritis and floating cartilage—which he considers entirely distinct. The cause of ill success in operation, which had led Hoffa and himself almost to give up surgery as a remedy, has been the restriction of motion due to too extensive scar tissue following the method deemed necessary in operating. Owing to the fact that, in this class of cases, the parts that interfere with the joint motion are so small, there does not, he says, seem to be any need of their complete removal, since they project into the joint but very little more than they normally should. Instead, therefore, of the U-shaped or lateral division of the capsule he does not open the joint, but cuts only down to the capsule on each side, retracts it, pulling the fringes out of the joint, and takes a reef in the capsule, thus preventing their further interference by taking up a fold of the capsule, securing it with sutures, and cutting it off inside of a specially devised clamp. The cut edges are finally sewed together with a fine suture which buries the exposed synovial border. The skin incision is closed and the leg kept in an extension splint for about a week. The after-treatment is simply keeping the joint at rest until healing has taken place. Motion is not restricted by such an operation, and the joint is practically normal a few days after the removal of the splint. The advantages claimed are: less danger than from the more extensive operation; better assurance of complete recovery; and avoidance of the long after-treatment and its discomforts.

Quinine Prophylaxis of Malaria.—E. R. Stitt questions the advisability of the prophylactic use of quinine against malaria, and quotes Ronald Ross that it is not

good policy to substitute a measure which does not exclude infection, but is merely extirpative in some cases, for positive prevention. Celli's statistics also show how much more effective mosquito protection, with or without quinine, is than quinine prophylaxis alone. In 1895, Stitt served as medical officer of the Ludlow Nicaraguan Canal Commission. It was his intention to recommend quinine as a prophylactic, but advised by a physician who had had experience in the employ of the canal company, he decided against it. This physician told him he had found that quinine in doses that could be well borne had little effect on the development of the disease; also, that it seemed that its previous prophylactic use made the individual less amenable to its curative effects and more subject to relapses. A few cases of malaria occurred while in camp, all yielding satisfactorily to large doses of quinine. The only member of the party who insisted on taking quinine as a preventive was the only one who had an attack on the trip home. A still more striking experience was with some marines who were stationed in an exposed situation near Panama for a month in 1906. During that time each man took nine grains of quinine daily as a prophylactic. Very little malaria occurred while on the isthmus, but the first day after sailing from Colon, there were 20 cases, the next day 53, and the third day 45. Notwithstanding the general administration of almost curative doses of quinine as a prophylactic, the condition of the marines on their arrival at Porto Rico was such that it was deemed necessary to get the men out of the tropics, and they sailed at once for Boston. During the five days' trip to Boston there were 215 acute malarial paroxysms among 298 men, in spite of the prophylactic use of quinine for those who were not cinchonized. The attacks were atypical—there was no frank chill. When the men arrived at Boston many were so weak and anemic that they were unfit to return to the tropics. The fact was noted that they did not seem to respond at all satisfactorily to quinine, even when it was given hypodermatically. Although from blood examinations made before the cases became so numerous the form of malaria was considered to be chiefly tertian, the clinical features indicated an estivoautumnal infection in many of the cases. From such facts as these, Stitt says he can but believe that malarial parasites may develop a resistance to quinine similar to that observed by Browning in trypanosomes, which moreover, seems to be inheritable by these organisms. He has himself seen actively motile amebas in the stools of persons undergoing quinine irrigation of the colon, and asks, if, instead of attributing this to the protection of the mucus, can we not suppose that these amebas have developed a resistance during the extended use of the drug? Another important consideration is that not only is the chief means of correct diagnosis, the finding of the parasite in the blood, made uncertain or useless by the driving of the parasites from the peripheral circulation, but the frank manifestations of the malarial paroxysms are masked so that clinical diagnosis is also made difficult, especially in the estivoautumnal forms of the disease. The physician referred to previously considered this a cause sometimes of delay of proper curative treatment resulting in difficult cases and more frequent relapses. At that time (1895) the fact of pathenogenesis in the microgametes was unknown. Now, thanks to Schaudinn, we have a scientific explanation. "The sexual forms in estivoautumnal fever do not develop for about ten days after the first paroxysm. In case we are giving quinine prophylactically we do not recognize the first attack, and as time goes by the gametes develop. These being resistant to quinine, as shown by the experiments of Gualdi and Marirano, are not extirpated. Later on the microgametocytes die out, leaving only the macrogametes. These by a parthenogenetic reproduction give rise to another nonsexual cycle and we have a relapse."

The Lancet, May 16, 1908.

Juvenile Tabes Dorsalis.—The histories of five cases are given by S. Stevenson. In three there was a definite hereditary specific taint. Cantonnet has been able to collect the histories of 89 cases, which material is briefly analyzed by the author. He notes that clinically confusion may arise between juvenile tabes and Friedrich's ataxia. In well-marked cases, however, the distinction is not difficult. The salient characteristics of Friederich's ataxia are (1) nystagmus, and (2) associated deformities, such as pes cavus and lateral curvature of the spinal column. The "lightning pains," the pupillary signs, and especially the optic atrophy of tabes dorsalis, are absent from the other affection. The bilateral atrophy of the optic disks coming on in young subjects might lead to some confusion with that peculiar abiotrophy known as "hereditary optic atrophy," which is liable to attack more than one member of a family at or about puberty. "Leber's disease," as it is sometimes called, is, however, usually preceded by optic papillitis, and even when the appearances of optic atrophy are present, yet the peripheral parts of the visual field retain their functions. The defect of vision, in other words, is in the nature of a central scotoma. Juvenile tabes may assume various clinical forms. Some cases are characterized by lightning pains in the legs and arms, ataxia of the limbs, and a reduction of the knee and ankle jerks. In a second group the prominent symptoms include amblyopia due to optic atrophy, together with changes in the pupillary reflexes, and abolition of the knee and ankle jerks. In this group ataxia is often absent, thereby bearing out the so-called "Benedikt's law," viz.: That ataxia symptoms disappear or fail to develop on the advent of optic atrophy.

A New Method of Restoring the Continuity of the Bowel in Cases of Excision of a Growth Low Down in the Sigmoid Flexure.—J. P. Lockhart Mummery thus describes an operation recently performed by him. The patient, having been placed in the Trendelenburg position, an incision was made through the outer part of the rectal sheath on the left side of the abdomen and extending right down to the pubes. On opening the abdomen, the operator found that the lower part of the growth extended down to within one and one-half inches of the rectosigmoidal junction, and that a loop of the sigmoid flexure above the growth had become adherent to, and was involved in it. This necessitated the removal of all but a few inches of the sigmoid flexure if the growth was to be removed. The sigmoid flexure was divided above the involved loop and the mesosigmoid was tripped up from the posterior pelvic wall and the vessels clamped as they were divided. This procedure was rendered necessary owing to the fact that some of the glands in the mesosigmoid were involved. As a result of the stripping up of the peritoneum the great iliac vessels were laid bare. The sigmoid flexure at the rectosigmoidal junction was now divided an inch below the growth and the adherent loops were removed. The peritoneum was brought together by stitches over the posterior pelvic wall and all bleeding points were ligated. At this stage, owing to the rectum not having been properly emptied previously to the operation, some soiling of the pelvic peritoneum unfortunately took place. Any of the ordinary methods of end-to-end anastomosis were quite impossible owing to the depth of the wound and to the fact that there was no stump of bowel below, but merely a hole in the pelvic floor. A glass Keith's tube was tied into the upper end of the sigmoid flexure and the free end of this tube, to the end of which a piece of large-bore rubber tubing had previously been attached, was passed down into the rectum from the abdominal cavity. An assistant then caught this with forceps introduced per anum and drew it out of the anus. By drawing on the Keith's tube the upper end of the sigmoid flexure was invaginated into the upper end of the rectum so as to form a kind of intussusception. Two or three silk stitches were then put in to prevent the invagination from coming undone. A drainage-tube was then inserted and the abdominal wound was closed in separate layers. The operation, which had taken some time, was well borne, and there was no shock. The author says that one of the chief advantages of the operation is that it enables the continuity of the bowel to be restored satisfactorily where stitching is out of the question. Furthermore, the bowels can be opened on the day after the operation without fear of rupture or leakage, as the sigmoid flexure and tube are gas-tight. In the case described the condition produced was practically a short artificial intussusception, the two peritoneal coats being in apposition, and the ends of the mucous coats close together, though not necessarily touching each other. Owing to the glass tube tied into the upper portion of the bowel no leakage could occur, and the ends of the bowel had about a week in which to become united to each other before there was any possibility of any strain being thrown upon the line of union; while the tube was still in position the bowels could be freely opened without any risk of leakage, and this was a very great advantage in the case of an anastomosis so near the rectum.

British Medical Journal, May 16, 1908.

Fracture of the Patella Treated by Mobilizing the Lower Fragment.—J. L. Thomas reports the case of a laborer, of forty-three years, who fractured his patella but did not consult a surgeon for several weeks. Various methods of nonoperative treatment failed to secure union. When first seen by the author, there was a gap of about an inch and a half between the fragments, and apparently nothing but skin existed in the gap between the examining fingers and the femoral surface. Nearly one year after the original accident Thomas operated, failing to get the fragments to within half an inch of each other by traction, and realizing that division of the quadriceps extension muscle is followed by much weakness of the limb, he decided to attempt to bring the lower fragment towards the

upper by mobilizing it. This was readily done, as the operator took advantage of his experience in the performance of arthrotomies and excision of the knee joint by Kocher's excellent method of the curved external incision and chiseling off the tubercle of the tibia, and applied it to this case. After making a long curved incision well down over the shin, the tubercle of the tibia with the ligamentum patella attached to it was chiseled off from without, care being taken not to detach the tendinous and periosteal attachments along its inner edge. By forcible traction upon the lower fragment of the patella and its ligament, the fragments were soon brought into contact, and their bared surfaces were kept in apposition by means of two loops of silver wire. The tubercle of the tibia retained considerable strength of anchorage in its displaced position by means of the untorn fibrous attachments of the ligamentum patella along its inner side. The wound was closed without drainage, and the patient left the infirmary in five weeks. Nothing could be more satisfactory than the immediate result of mobilizing the lower fragment, while the junctional result in time was also satisfactory.

A Method of Obtaining Rapid Healing of Acute Abscesses.—The method described by J. Phillips is based on the theory that if all the dead material in a localized abscess is removed and means taken to prevent the collection of further dead material in the abscess cavity to act as a culture medium, rapid healing will take place. The following rules are given: (1) Cleanse the skin as in operating on sterile tissues. (2) Make an incision long enough to permit of the pus being freely evacuated and the pyogenic membrane rubbed clean and smooth with gauze wrapped round the finger. (3) Having emptied the abscess cavity as completely as possible, pack it tightly with gauze (we use 1 in 1,000 mercury perchloride gauze, dry) and apply a wool dressing and bandage as firmly as possible. (4) At the end of forty-eight hours remove the packing and dress the wound as if it were a simple incision; that is, do not pack or drain at all, but simply fix a gauze and wool dressing firmly in place with a bandage. This dressing will require changing only once in three or four days until the incision is soundly healed, and it will be found that the sides of the abscess cavity unite promptly and that there is no outpouring of pus from it. From the time when the packing is removed it is practically a simple incised wound that is being treated. Histories of six illustrative cases are given.

Calcium Chloride in Melæna Neonatorum.—S. C. Legge was called to see a child which had been delivered by a midwife. He found the clothes stained with blood and saturated with a dark, treacly fluid, and from the anus bright blood was issuing. The child appeared pale and collapsed, previously having been the ruddy hue usual to infancy. There was no vomiting or jaundice. He paid two further visits during the day, and found the discharge still continuing, but of a brighter color. On his second visit he took with him a solution of calcium chloride, a teaspoonful of which was given every half hour (the child during the following thirty-six hours taking twenty grains). On the following morning the discharge was less in amount, and the child appeared better. On the third day the discharge stopped, and the child made a rapid recovery. The child took the breast well throughout. The midwife informed me that the labor was normal in all respects. There was no sign of sepsis in mother or child, and the latter appeared healthy in other respects. The cord was quite healthy, coming off on the fifth day. The author thinks that the calcium chloride had a beneficial effect in this case, as when first seen the prognosis seemed anything but good.

Berliner klinische Wochenschrift, May 11, 1908.

Hemolytic Streptococci in Puerperal Septicemia.—Fromme and Heynemann say that streptococci are found in the vaginæ of the majority of pregnant and puerperal patients; like organisms are responsible for the septicemia of the puerperium. All the virulent streptococci which they obtained from the blood, the peritoneal cavity, or the endometrium of such cases showed one common property: They had hemolytic action upon the blood-agar plates. The finding of such organisms in patients suffering from fever in the puerperium is evidence of the serious character of the disease. The absence of such a streptococcus permits a favorable prognosis even in the presence of severe symptoms.

Münchener medizinische Wochenschrift, May 12, 1908.

The Significance of the Achilles Tendon Reflex.—Couzen has examined 3,290 patients for the presence of this reflex, which consists in quick plantar flexion of the foot when the Achilles tendon is smartly tapped with a percussion hammer. He has never observed its absence in healthy persons. Such absence always meant some pathological condition of the nervous or muscular system, and was observed in cases of alcoholic neuritis and of tabes dorsalis, and in later periods of sciatica. The author attributes the same importance to this reflex as is usually given to the patellar reflex.

Deutsche medizinische Wochenschrift, May 7, 1908.

Alimentary Lactosuria in Diseases of the Stomach.—A. von Halacz administered 150 grains of lactose to each of forty-five patients suffering from various diseases other than those of the stomach. In no case did lactosuria result. The same quantity of sugar was given to each of the twenty-three other individuals, seven of whom came to autopsy with carcinoma of the stomach, ten had a palpable tumor of the greater curvature, two had dilated stomachs with carcinomatous disease elsewhere in the abdomen. The condition of the remaining four patients is not stated. In twenty-two of these twenty-three cases lactosuria resulted. The author thinks that the lactosuria was caused not by the existence of carcinoma or other disease, but was due to dilatation of the stomach.

Diet in Motor Insufficiency of the Stomach.—Cook says that the use of a fat and proteid diet is diminished motor activity of the stomach is usually followed by great improvement or disappearance of the symptoms. He cites four cases in which the digestion of fat as measured by the refractometric method of Strauss showed progressive improvement on such diet. For the diagnosis of coexistent dilatation, Cook uses the maximum distance of the stomach, as determined by percussion, to the right of the middle line. This distance he considers more trustworthy in pointing to the existence of dilatation than the determination of the lower curvature of the stomach.

French and Italian Journals.

Puerperal Infection with the Staphylococcus and Colon Bacillus.—Marquis has made examinations of the blood of his cases of infection in order to obtain evidence of the frequency of infection by other bacteria aside from the streptococcus, especially the staphyloccoccus and colon bacillus. He has found four cases of the former and three of the latter, of which he gives us the histories. He finds that when in pure culture and without metastases neither of these infections are very fatal, most cases recovering. Both of these varieties are of somewhat long duration, the colon bacillus especially producing an infection that may run even for several months. Serodiagnosis is most valuable in differentiation of these infections from that with the streptococcus.—*Annales de Gynécologie et d'Obstetrique,* April 1, 1908.

Internal Secretion of the Ovary.—M. Hughes Alamartine, after a careful consideration of the evidence for the theory that there is an internal secretion of the ovary of importance to the body, states that it is his conviction that this fact is established by the evidence we now possess. There is a correlation between this gland and the suprarenal capsules, and other glands which have an internal secretion. The cells of the interstitial glandular substance of the ovaries resemble those of the suprarenals. The corpora albicantia do not develop until after ovulation has begun. There are formed in the ovaries toxic substances, and this goes to show that the action of this organ is to remove from the body substances that are unfavorable to its action, and which are brought to the ovaries by the circulation. The two functions, antitoxic and sexual, need not be separated. The toxins elaborated in the ovary are transformed into useful substances, some are rejected with the ovule to aid in the sexual reproduction; others are absorbed by the uterus to prepare the mucous membrane for fecundation and assure the development of the ovum. Still others go throughout the organisms and produce the so-called secondary ovarian characteristics—*Gazette des Hôpitaux,* March 14 and 21, 1908.

The Tuberculin Reaction and Its Diagnostic Value in Infant Tuberculosis.—Olimpic Cozzoline has experimented with the old tuberculin of Koch in the diagnosis of infantile tuberculosis. Forty-seven infants were injected, a febrile reaction being obtained in twenty-one. He concludes that in suitable cases the injection of tuberculin has an undoubted diagnostic value in babies. It has no bad effects when the proper precautions are observed. The type of the reaction is variable; the commonest is a rapid ascent and descent of temperature, but in some the reaction lasts for some time. The *stichreaktion* of Escherich has almost no diagnostic value. The opthalmoreaction does not give sufficiently certain results to take the place of the true tuberculin reaction obtained by injection.—*Rivista di Clinica Pediatrica,* February, 1908.

Society Reports.

AMERICAN MEDICAL ASSOCIATION.

Fifty-ninth Annual Session, Held in Chicago, June 1, 2, 3, 4 and 5, 1908.

(Special Report to the MEDICAL RECORD)

HOUSE OF DELEGATES.

Monday, June 1—First Day.

DR. JOSEPH D. BRYANT OF NEW YORK, PRESIDENT, IN THE CHAIR.

Address of the President.—Dr. JOSEPH D. BRYANT, after acknowledging the honor bestowed upon him, discussed the functions of the presidential office, pointing out the benefits to be derived by cooperation by the President with his colleagues in official labors, as is done in other corporate bodies. Referring to the proposed amendment of the Constitution to admit to membership in the House of Delegates ex-Presidents of the Association, he recommended cautious action in a matter which, while disturbing the equilibrium of constituted State representation, seemed not to contribute a commensurate gain. The clause of the Constitution providing that "no member of the House of Delegates shall be eligible to the office of President or Vice-President" was a wise and healthy measure. Referring to the work of the Council on Pharmacy and Chemistry, he said he had been much disturbed by charges of ungentlemanly, oppressive, and illegal treatment, made by certain pharmaceutical houses against responsible officials of the Association, one complainant averring that even if he were sustained by the courts, still his business would be destroyed by retaliatory cooperative action of the members of the Association. Recommending that such a situation should be met by the members of the profession in a spirit of good-citizenship, he asked whether those opposed to the policy which stands for the securing of trustworthy medicinal agents were entitled to the same consideration as those are who approved of that policy.

The work of J. N. McCormack of Kentucky was commended as being of importance in elevating the tone and the standard of the medical profession.

The principles of moral philosophy being hard to instil into the minds of physicians of established thought and habit of action, Dr. Bryant considered it important that undergraduate and postgraduate instruction in ethical medicine should be required of medical schools, and recommended that a standing committee on principles of moral philosophy as applied to medicine should be constituted, with the view of elaborating still further ethical principles, and, so far as practicable, establishing in this respect uniformity between the medical profession of this and other countries. Plausible measures directed to the regulation of animal experimentation being abroad in the land, so adroitly drawn and so cleverly presented as to conceal their grave possibilities, the President cautioned medical men loyal to the spirit of scientific endeavor against thoughtlessly giving strength to the foes of scientific medicine. The speaker recommended that the duties of the House of Delegates be simplified, so that membership therein should not become so onerous as to eliminate from its councils men whose ceaseless toil makes for higher station in medicine. He then paid a tribute to the memory of the late Dr. Nicholas Senn, whose indefatigable energy and ceaseless activity had contributed so greatly to the honor and glory of the calling of medicine. In March of this year, the President of the United States had invited the American Medical Association to take part in the Conference on the Conservation of Natural Resources. In response thereto, Dr. Bryant attended the Conferenec as the official representative of the Association, and on its behalf pledged the support in the purposes of the Conference, not only of the members of the American Medical Association, but of the entire profession of the land. He urged the House of Delegates to take prompt and decided action, thus showing appreciation of the invitation and determination to aid the movement in every possible manner.

Report of the General Secretary.—Dr. GEORGE H. SIMMONS presented this report: On May 1, 1907, the membership of the Association was 27,515. During the year the total loss in membership from all causes had been 2,334. There had been added during the year 6,172 names. The membership on May 1, 1908, was 31,343, a net gain for the year of 3,828. The State associations had been urgently requested to express their views on the subject of branch associations, and acknowledgments of communications sent on this subject had been received from thirty-six States. Of these, two had voted in favor of branch associations, nine had voted against, and twenty-five had taken no action. Much difficulty had been encountered in enforcing the provisions of the by-laws regarding the membership because different State associations had different rules on such subjects as the date of the beginning of the fiscal year, the date at which dues must be paid, etc. As the Association and its various constituent parts had been better organized, and as the work of the various secretaries had become more burdensome, it was necessary to formulate a uniform system of procedure for the various State associations and component county societies to follow. It was therefore recommended that this entire matter be referred to a committee of three, at least two of whom should be secretaries of constituent State associations, with instructions to secure data regarding the present provisions of the constitutions and by-laws of the various State associations on these points, as well as the procedure followed by State and county secretaries, and to report its findings and recommendations to the House of Delegates at the next annual session. A number of communications had been received from physicians practising in Porto Rico and in Alaska regarding the organization of constituent associations in those territories. In each case the writer had been advised by the General Secretary's Office that such an organization was desired, and urged to take the lead in effecting it. Nothing had as yet resulted from the correspondence, but it was hoped that before long a society could be organized in each of those territories that would become a branch of this Association. A communication had been received from the American Association for the Advancement of Science, asking the American Medical Association to appoint two of its members to represent it in the Council of that association. It was believed that this invitation should receive favorable consideration. At present all of the sciences were represented in the Council, and it seemed in the interests of both medicine and the natural sciences that this representation should include practical and scientific medicine.

Report of the Board of Trustees.—Dr. T. J. HAPPEL of Tennessee, Chairman of the Board of Trustees, presented this report, which was accompanied by the customary audit company's statement which showed a net revenue for the year of $28,808.68. The increase of dues over the preceding year was $19,751.09; of subscriptions, $2,875.53; of advertisements, $21,235.82. The total number of copies of the *Journal* issued during 1907 showed an increase of 12½ per cent. over the preceding year.

The Board felt that the time had fully come when the Association could and should do away with the expense of a salaried organizer. The services rendered the Association by Dr. McCormack had resulted in an inestimable amount of good. The organization had, however, now been perfected and placed on such a footing that each State should in the future maintain its own status. There had been expended in this work a sum of not less than $40,000, and while, as previously stated, great good had

resulted from the special work done in this line, and the profession had received a *quid pro quo* for every dollar spent, yet money was needed to push other undertakings; hence their recommendation to discontinue this branch of the work, putting the matter into the hands of the different State associations. The American Medical Association would ever owe Dr. McCormack a debt of gratitude for the great work which he had done in his special department. In accord with the recommendations of the House of Delegates in 1907, the Board had arranged with Dr. McCormack to enter vigorously on the work therein suggested. The Board thought that his time might now be more profitably employed in presenting pure food matters, and the need of uniform State laws governing the practice of medicine before the legislatures of the different States, and as an educator of the public in matters medical, as he had been chiefly doing during the past year, and the Board suggested that he be requested to continue in that work for a time yet.

A tabulated statement was submitted showing the receipts and disbursements of the Atlantic City meeting, the net cost of which to the Association was $4,499.98.

Commenting upon the work of the Council on Pharmacy and Chemistry, the report stated that the importance of the work done by that Council and the Association in correcting some of the evils of patent and proprietary medicines was generally recognized. The work of the Chemical Laboratory in investigating and publishing the composition and quality of the remedies, both proprietary and official, prescribed by physicians would stimulate manufacturers to improve and maintain the quality of their products, and would enlighten physicians as to the quality of the drugs on which the lives of their patients depended.

The following had been appointed members of the Committee on the Revision of the Pharmacopœia: Reid Hunt, Washington; E. E. Hyde, Chicago; George Dock, Ann Arbor; Robert A. Hatcher, New York; W. S. Thayer, Baltimore; S. Solis-Cohen, Philadelphia. New members of the Council on Pharmacy and Chemistry had been named as follows: D. L. Edsall, J. A. Capps, R. A. Hatcher, and Otto Folin. A staff of fifteen clinical consultants to the Council had also been selected. The trustees took occasion to commend in the strongest terms the great work done by the Council on Medical Education in eliminating weak and worthless colleges and improving the standard of medical education.

The reserve fund carried had stood the Association in good stead during the recent financial depression and the Trustees recommended that the amount of such reserve be fixed at $200,000, since a fair proportion of the Association's profits resulted from its ability to discount its bills. The Trustees suggested the advisability of making an annual appropriation of $500 for an essay on subjects relating to internal medicine.

An amendment to the By-Laws was recommended providing that anyone who had been a member in good standing of the Association for twenty years and who had been placed on the retired list of his State association, should, on his request, be placed by the Secretary of the American Medical Association on the retired list of the members of the Association. Retired members should be exempt from the payment of dues.

Report of the Committee on Medical Legislation.—Dr. C. A. L. Reed of Ohio, Chairman. Under the head of national legislation the Committee called attention to the passage of the bill for the reorganization of the Army Medical Department, which was a decided advance inasmuch as it provided an adequate medical staff for the Army, abolished the contract surgeon system, and provided for expansion in time of war. Three bills relating to the Medical Department of the Navy, providing respectively for the reorganization of the hospital corps, the appointment of dental surgeons, and the establishment of a corps of trained women nurses, had not, for one reason and another, been enacted into law. Reference was made to the desired increase of the pensions of the widows of Drs. James Carroll and Jesse W. Lazear of the Yellow Fever Commission. The work of the Committee bearing on State legislation was discussed. The question of uniform laws regulating the practice of medicine in the different States had long been recognized as one of vital importance both to the profession and to the public. The tabulation of material upon which to base an attempt at securing a uniform medical practice act, a task of considerable magnitude, had been inaugurated under the direction of the Committee and would be pushed to conclusion as rapidly as might be compatible with accuracy. Pending the completion of that investigation and the preparation of a model bill, it was recommended that only absolutely necessary changes in the State practice acts be undertaken. A model bill to provide for State legislation on vital statistics had been recommended to those States as yet without satisfactory regulation on that subject. It had been impossible to formulate a model pure food and drugs bill capable of adoption by all the States. Accordingly, the laws of Kentucky and Tennessee, respectively, two of the best State laws as yet adopted, had been issued in the form of pamphlets for distribution. The establishment of a Bureau of Medical Legislation had greatly increased the efficiency of the organization.

Report of the Board of Public Instruction.—Dr. J. G. Clark of Pennsylvania, Chairman. Since the appropriation had been granted in February by the Board of Trustees for the work, the Board had elaborated a provisional scheme as yet only suggestive in character. The first articles to appear would be along the line of preliminary education. The first writers would be chosen from the ranks of scientific workers in no way connected with the practical side of surgery or medicine. Gynecological and sexual matters would not be published, but would be taken up through circular letters to physicians, or by carefully prepared monographs by authorities which would be of the greatest value and could be judiciously employed for educational purposes by the medical profession in their association with their patients. For the present therefore there would be no attempt to exploit any of these subjects in the lay press. No matter which was open to controversy in the medical profession would appear in the public press, and only those facts concerning which there was general accord would be presented. Matters of treatment would be discussed without allusion to details. As to whether or not articles should be signed, the Board requested an indication of the preference of the House of Delegates. The Board believed that two lecture systems were advisable, one under the direct authority of the Association, national in character, and the other a local course of lectures under the auspices of county societies. The Board advised the establishment by the various State societies of State boards of public instruction. Preliminary notice of forthcoming articles in popular periodicals was proposed, whereby physicians might obtain advance information as to the character of the articles about to appear. The Board submitted a definite outline, regarding which suggestions from members were solicited. Its principal divisions were: (*a*) *Medicine*: Bacteriology. The Specific Infections. The Intoxications. The Constitutional Diseases. Diseases Due to Animal Parasites. The Digestive System. The Respiratory System. The Heart. The Diseases of the Kidneys. (*b*) *Nervous Diseases*: Anatomy and Physiology of the Nervous System. Functional Nervous Diseases. Organic Nervous Diseases. (*c*) *Surgery*: History of Surgery from Ancient Times to the Present Day, etc. Abdominal Surgery. Surgery of the Bones. Orthopedics. Nerve Suturing and Plastic Surgery. Army Surgery. (*d*) *Hygiene*: School Hygiene. Domestic Hygiene. Personal Hygiene. Water. Garbage and Sewage. Quarantine. (*e*) *History of Medicine.*

Discussion of Dr. McCormack.—Dr. Philip Mills Jones of California offered a resolution whose purpose was to eliminate from the Report of the Board of Trustees certain portions thereof recommending that the Association do away with the expense of a salaried organizer, stating that the organization work had reached such a stage that each State should now maintain its own status, and recapitulating the expense which the organization work had been to the Association. Dr. Jones considered these statements a disparagement of the work of Dr. McCormack. He believed, therefore, that these statements should not stand as an expression of the sentiment of the House of Delegates.

Dr. T. J. Happel of Tennessee, Chairman of the Board of Trustees, disclaimed any intention on the part of the Board to minimize the value of the work of Dr. McCormack. He called attention to the expression commendatory of Dr. McCormack in the very paragraph under discussion. It was the desire of the Board of Trustees, he said, to report to the House of Delegates what had been done along the line of organization. Dr. McCormack had been continued by the Board of Trustees, under the authority of the House, during the past year. The Board believed that the work of organization had been completed. No reflection whatever had been intended in the report, but a simple plain statement of no further need. The work of organization had progressed to a point where it should be continued by the States, and Dr. McCormack's work should be directed along educational lines, to pure food and sanitary matters, etc.

Dr. L. D. McMurtry of Kentucky was sure that the House had been pleased to listen to the explanation of Dr. Happel. He was aware of the sacrifice made by Dr. McCormack in the prosecution of the organization work. He knew that Dr. McCormack desired to retire from that work. He was convinced, however, that the organization had reached a point where it needed the fostering care of the Association more than at any other time. Dr. McCormack's work was that of organization. He discussed pure food matters, it was true. But why should it have been indicated in the Trustees' report just exactly what he should say to the people? Why should not the report say: "Go on in this good work, and we'll stand behind you!" The matter of expense was an absurd one to consider in the House. The treasury was able to bear the expense, and every county society organized brought into the treasury many times the amount expended. He did not want to have put on record the slightest suggestion that Dr. McCormack's work was not perfect.

Dr. Alexander R. Craig of Pennsylvania proposed an amendment to the resolution to the effect that it and the explanation made by the Board of Trustees be referred with the Report to the reference committee. The resolution was adopted.

Investigation of Drugs by the Public Health Service.—Dr. Happel presented a supplementary report of the Board of Trustees, embodying a communication from Dr. H. L. E. Johnson of the District of Columbia to the effect that preliminary arrangements had been made whereby the Treasury Department, through the Public Health and Marine Hospital Service, would cooperate, under rules to be formulated, with the Council on Pharmacy and Chemistry in the investigation of drugs, etc. A Federal appropriation of $12,000 had been made to aid the American Medical Association in making these investigations. The Board of Trustees asked that a vote of thanks be extended to the Secretary of the Treasury for his aid in securing the appropriation and his promised aid in carrying out the investigations, and recommended that the report be turned over to the reference committee to be considered in connection with the Report of the Board. It was so ordered.

AFTERNOON SESSION.

Report of the Committee on Organization.—Dr. J. N. McCormack of Kentucky, Chairman, discussed his itinerary for the year. In September he addressed the American Pharmaceutical Association, where he outlined the necessity of a system of cooperation between the two associations. The American Medical Association was endeavoring to bring about a return to the use of the pharmacopœia and the national formulary in prescription writing, and to drive out the nostrums. He found enthusiastic support from the better class of manufacturers, but was immediately made the object of the most severe attacks from those who would be the greatest sufferers from such a movement. He favored a careful study of the question, whereby standard formulæ of known value might be substituted for proprietary remedies. He recommended to the House of Delegates that a conference committee be created to meet a similar committee from the Pharmaceutical Association. He commented on the rapid adoption by the county societies of the post-graduate course of study now running in the *Journal*. During the year his work had taken him into West Virginia, Indiana, Virginia, Kentucky, Ohio, Louisiana, Mississippi and Pennsylvania. He made addresses at Yale University and before the American Health League in New York. Among all classes of society he had found promise of support for all reforms proposed. He discussed the inadequacy of the present training in medical schools. How to gain practice, how to collect accounts, how to keep up studies, the dangers of contract practice, and the division of fees, all such problems were quite neglected in the medical colleges at present. He spoke also of the absolute necessity of higher entrance requirements. Only by such fundamental changes would it be possible to correct conditions wherein one-third of all sickness and one-third of all deaths resulted from unnecessary diseases. Schools had never adopted reforms except under compulsion of law. The work of organization would have to be kept up until students educated according to these requirements formed the body of the medical profession.

Report of the Committee on Ophthalmia Neonatorum.—Dr. F. Park Lewis of New York, Chairman. The average of the new admissions in the fall of 1907 to ten schools for the blind, representing eight States and the Province of Ontario, was 25 per cent. needlessly blind. For the last eight years the pupils of the Pennsylvania School for the Blind had run from 23 per cent. to 50 per cent. needlessly blind. To meet such conditions, the committee considered three things necessary: First, exact data; second, control by State authorities; third, united and concurrent action on the part of all those who knew what to do and were willing to aid in stamping out this pestilence. The first need had been met through circular letters to the State medical societies, responses to which were immediate and gratifying. As to the procedure to be adopted, the first step of importance was to secure a general registration of births. The second essential was the registration of midwives. It did not seem practicable to make ophthalmia neonatorum a reportable disease. The distribution was proposed of tubes containing a proper prophylactic, preferably a 1 per cent. solution of silver nitrate, by the health departments. The result sought to be accomplished might be greatly facilitated by an international congress devoted to the prevention of unnecessary blindness. Such a congress should include for its consideration not only ophthalmia neonatorum, but all forms of preventable blindness, such as trachoma, and preventable accidents due to peculiar employments. If such a congress were to be held in Washington in 1910 its possibilities might be outlined at the Ophthalmological Congress, and a plan of procedure adopted which might do more than any other single movement to lessen the unnecessary blindness of the world.

Report of Committee on Section on Tropical Medicine.—Dr. L. Hektoen of Illinois, Chairman. The Committee regarded the formation of such a section as unnecessary at the present time, because papers and discus-

sions on topics especially related to tropical medicine could be presented very well in existing sections, more particularly the sections on Practice of Medicine, on Hygiene and Sanitary Science, and on Pathology and Physiology.

Report of Committee on Scientific Research.—Six grants of $200 each had been made, to be applied to work to be reported at the Chicago session. The Committee recommended an increase of the appropriation to $1,000 a year. The report was referred to the appropriate reference committee.

Report of the Davis Memorial Committee.—The committee reported progress, Massachusetts having contributed $500. Request was made that, besides the appropriation of $5,000 which the Committee confidently expected from the Association, the several State societies be invited to appropriate during the coming year such sums as their judgment might warrant for this purpose. The report was referred to the appropriate reference committee.

A Uniform Medical License Law.—Dr. G. Wythe Cook of the District of Columbia offered a resolution providing that the Committee on Medical Legislation or a special committee of five to be appointed by the Chair be instructed to formulate a medical practice law applicable to all States and Territories, the license of each State to be recognized by every other State and Territory, and that the law so formulated be recommended to the various State associations. The resolution was referred to the Reference Committee on Medical Legislation.

Report of the Council on Medical Education.—Dr. A. D. Bevan of Illinois, Chairman. The report of the Council, going into great detail, is summarized as follows: (*a*) There are 335 medical colleges in the civilized world, of which number the United States has 161, or 48 per cent. (*b*) All the medical schools of Europe are medical faculties of universities, or are under the direct control of universities. There are no proprietary schools, such as are found in this country. (*c*) The United States is the only leading nation which does not require a thorough preliminary education in physics, chemistry, and biology of every matriculant in medical colleges. (*d*) Comparison with European medical schools shows that medical education in the United States is deficient both as regards preliminary requirements and in the length of the medical course. (*e*) As regards the time necessary to complete the course in medicine, the majority of European countries agree with the ideal standard adopted by the American Medical Association at Portland in 1905. (*f*) Primary and secondary education in the majority of European countries may be finished after twelve years of study, agreeing with the time required to complete the public school courses in the United States. (*g*) According to the claim of leading educators, the work in the secondary schools of several European countries is the equivalent of the standard high-school course in the United States, plus two years of work in a university. (*h*) This would seem to indicate that, in the results obtained, twelve years of study in primary and secondary schools in Europe are equal to fourteen years of study in the United States. (*i*) Eight more colleges have been rated below fifty per cent. as a result of inspections made by the Council during the past year. The number of colleges thus listed as unsatisfactory now reaches 39. (*j*) Thirty-two reputable medical colleges offer a combined course whereby the student may obtain the baccalaureate and M.D. degrees in six years. (*k*) Fifty-three medical colleges either already require for admission one or more years of work in a college of liberal arts, including courses in physics, chemistry, and biology, or have voted to do so in 1910 or before. (*l*) Of the medical colleges in the United States several are probably equal to any in the world, and the majority are voluntarily keeping abreast of the demands of modern medicine. There are some, however, which will probably not do so until the State examining boards adopt and enforce higher requirements. (*m*) The examining boards of Minnesota and North Dakota, beginning in 1912, will require preliminary education equal to two years of university work. The boards of Colorado, Connecticut, and South Dakota will require the equivalent of one year of university work. (*n*) Thirty-four States have now established reciprocal relations with four or more other States. Several other State boards have been given legal authority to do so, but are not taking advantage of it. (*o*) More laws influencing medical education have been secured during the past ten years in this country than in all previous years, and there is a rapid trend toward uniformity of requirements.

Report of the Director of Post-Graduate Work.—Dr. John H. Blackburn of Kentucky reported that the suggestive outline of study submitted to the house last year had been sent out to selected workers in the profession all over the country for suggestion and criticism. The replies generally were confined to mere commendations of the plan, but many contained suggestions as to the subject-matter to be covered, especially in the line of materia medica and therapeutics. Following these suggestions so far as possible, a course for the first six months was published in September, and since then a weekly elaboration of the outline had appeared in the *Journal*. The outline for the second six months was issued in March of this year. The course had been adopted, according to notifications received by Dr. Blackburn, by ninety county societies. The outline for the second year was now in preparation. There was in contemplation a regular quarterly examination, with proper credits, and a certificate or diploma on the satisfactory completion of the four years' course. The great aim of the course of post-graduate study was the perpetuation of the county society, on the active operation of which unit of organization would depend the success of the American Medical Association.

Report of Committee on Nomenclature and Classification of Diseases.—Dr. Frank P. Foster of New York, Chairman. The individual members of the committee had already done a great deal of work on the proposed revision, but were not able to complete it in time to be submitted at the present session. It recommended the provisional adoption of the nomenclature of diseases of the Royal College of Physicians of London for use in naming diseases and injuries in clinical reports, and of the International Classification of Diseases and Causes of Death in official mortality and morbidity reports. If the present committee should be continued, it was confidently expected that a completed nomenclature and classification would be submitted at the session of 1909.

Tuesday, June 2—Second Day.

Report of the Reference Committee on Medical Education.—Dr. H. D. Arnold of Massachusetts, Chairman. The committee extended its congratulations to the Council on Medical Education on the success of its work during the year, and recommended the continuance of the campaign of publicity, and of the efforts to induce more schools to adopt higher standards of admission.

Report of the Reference Committee on Reports of Officers.—Dr. Wisner R. Townsend of New York, Chairman. The committee recommended that all suggestions in the President's report relating to matters contained in the present Constitution and By-laws be referred to a special committee of three.

The committee recommended the adoption of the following resolution, approving of the recommendations of the President relating to the teaching of the principles of moral philosophy as applied to medicine.

A resolution was recommended: (*a*) That animal experimentation has been of incalculable benefit to science and art, the progress of which is as absolutely dependent upon experimental methods as are all the physical and natural sciences. (*b*) That no abuse of the practice of animal experimentation in this country has been shown

to exist to warrant specific legislation, nor is there any probability of such abuse arising. (*c*) That the unrestricted performance by proper persons of scientific experiments on living animals is essential to the maintenance and progress of medicine and biology." The resolution was adopted.

The committee recommended that measures be taken to bring about a uniformity of membership regulations in the constituent bodies, as outlined in the report of the General Secretary. It also recommended the striking out from the Trustees' report the portions which had been objected to at Monday's session, and the substitution therefor of a paragraph to the effect that the American Medical Association owed Dr. J. N. McCormack a debt of gratitude for his work as organizer, and it was recommended that he be requested to continue his work along that line. The appropriation for the continuance of the post-graduate work was recommended by the committee, and the recommendation was adopted by the House.

Dr. William H. Welch of Baltimore presented a resolution directing that the Board of Trustees establish a committee on the defense of medical research, whose duty it should be to make proper presentation before legislative bodies on the question of animal experimentation. Dr. Vander Veer of New York urged the necessity of such a measure, and on motion the resolution was referred to the Board of Trustees with the hearty indorsement of the House of Delegates.

Dr. W. H. Sanders of Alabama presented a resolution providing for an investigation of the question of a national charter for the Association, and for other purposes, which was referred to the Reference Committee on Medical Legislation.

Dr. C. S. Bacon of Illinois offered a resolution providing for a Conference Committee of Five to cooperate with the Committee on Medical Legislation and with the committees of other interested organizations to seek the amendment of the patent and trade-mark laws so as to prevent the monopolization of pharmaceutical preparations and the consequent retardation of the development of new therapeutic agents.

Committee on the Davis Memorial.—Dr. Henry O. Marcy of Massachusetts said that the neglect of the American Medical Association to take the lead in appropriating funds for the Davis memorial had been such a handicap to the committee in the solicitation of funds from constituent bodies that unless the House of Delegates was prepared now to make a contribution of $5,000 the committee would recommend the return of funds already contributed and ask to be discharged.

Dr. A. McCormack of Kentucky recommended that the policy of the *Journal* in restricting its advertising to pharmaceutical preparations indorsed by the Council on Pharmacy and Chemistry be communicated to constituent bodies, with the recommendation that they follow the same rule in respect to their organs.

GENERAL SESSION.

Tuesday, June 2—First Day.

Dr. Joseph D. Bryant of New York, President, in the Chair.

The Right Reverend Charles Edward Cheney, D.D., Bishop of the Reformed Episcopal Church, made the opening prayer.

A greeting was extended by President Bryant on behalf of the organization, the history of whose remarkable growth and increasing power for public good he touched upon. Quoting the words of the Constitution setting forth the object of the Association—the efficient organization of the medical profession of the United States, the growth and diffusion of medical knowledge, and the enlightenment of public opinion in regard to the broad problems of hygiene—this object he declared to be rapidly nearing accomplishment. He urged that in all questions which related to the enhancement of the public health and welfare, the public should implicitly trust the members of the medical profession, who pledged themselves to fulfill in all respects their obligations as citizens and professional men.

His Excellency, Charles S. Deneen, Governor of Illinois, in an address of welcome, said that the medical profession was, without doubt, of all professions, the one upon which mankind came nearest to entertaining a unanimity of opinion. Everywhere health was deemed the greatest of earthly blessings, and everywhere the profession which was devoted to its maintenance was ever deemed the greatest of professions. Moreover, in no other profession did men display greater devotion to the general welfare of mankind. The American Medical Association had been one of the most active agents in the advancement of the science of medicine and in the establishment and maintenance of the high code of ethics to which the members of the medical profession conformed. Its reward lay in the universal confidence with which the profession was regarded in all parts of the country.

The Mayor, Hon. Fred. A. Busse, not being able to be present, a welcome to the Association on behalf of the City of Chicago was extended by Dr. W. A. Evans.

Addresses of welcome were made by Dr. J. W. Pettet, President of the Illinois State Medical Society, and Dr. H. B. Favill of the Chicago Medical Society.

Address of the President.—Dr. Herbert L. Burrell of Boston, being introduced by Dr. Bryant, then delivered his presidential address (see page 925).

Afternoon Meeting.

Oration on Surgery.—Dr. George W. Crile of Cleveland, at the afternoon session, delivered this oration, taking as his subject "The Problem of Cancer" (see page 929).

Evening Session.

At the Third General Session, held at 7:30 P.M., the following orations were delivered:

Oration on Medicine.—Dr. William Sydney Thayer of Baltimore delivered this oration, taking as his subject, "Some Relations of the Physician to Public Duties and Opportunities." The physician, he said, had always been and, from the very nature of his calling, must be, more or less a public character. In the smaller community he was a public character in the sense that he was a common source to which the citizens repaired for advice, not only concerning their physical and mental but often also their material well-being. In the larger centers of population he was a public character in that it was on his direction, on the results of his studies and research that the community depended for the organization of those more general, broader sanitary measures which are demanded to meet the exigencies ever arising and multiplying with the growth of large urban communities. In the early days of this country, when there were no large cities, the physician exercised this influence individually among his patients, as the family friend and adviser. With the growth and development of the nation and the great advances made in medical knowledge, the functions of the physician had considerably broadened. There was now an increasing body of students, of physicians who accomplished their function, and a most important and radical function it was, in the study of special scientific problems—a life widely different from that of the country doctor of old.

At the same time, the crowding together of the population into great cities had brought with it new dangers. The poisoned well might affect one or two families at most. The poisoned water supply of a great city might affect thousands. Scarlet fever in the country town had few victims and might be more or less readily controlled. In congested tenements it was a widely different problem. These new dangers involving the broad questions

of public health and prophylaxis, questions of drainage, of water, of milk and food supply, of the care of contagious diseases—these demanded the individual attention of men who had had special training. The great questions of water supply and of drainage could not be attended to properly by the engineer alone, nor could the protection of the city from epidemics of infectious disease safely be entrusted to boards of health consisting only of public-spirited citizens; both were dependent on the advice and assistance of the trained sanitarian. In almost all large enterprises to-day the aid of the physician was sought, as for instance, in the organization of the relief departments of great railways and corporations and in large department stores. But the distinctly public duties of the physician were by no means confined to exigencies arising in large centers of population. There were, in the history of mankind, examples of the gradual or sudden desolation of extensive districts by the insidious influence of diseases now known to be in great part preventable. Such an example was seen in the history of Greece, in the ruin of that country, and the degeneration of its people as a result of malaria. The work of the physician was to prescribe measures of reorganization in this and other countries devastated by malaria, as was in fact being done to-day in Italy, where the mortality in the fever-ridden districts had been reduced two-thirds in five years. Another example was found on the Isthmus of Panama. The French, with unexcelled mechanical skill and energy, had failed to dig the canal, failed largely because of the dreadful and continued mortality among the workmen. The United States took up the work. In the meantime there had come the great discoveries of Ross and Grassi and Bignami and Bastianelli, completing those of Laveran, concerning malaria, and the vital and illuminating contributions of our own Reed, Lazear, Carroll and Agramonte, with regard to yellow fever. And now the Panama Zone compared favorably, as to sanitary conditions, with the more healthy parts of this country. Yellow fever, though on all sides, was here unknown. It was the greatest triumph of preventive medicine that the world had ever known. A few months ago, the speaker said, he had the good fortune to listen to an account by a distinguished foreign physician, of the work at Panama whence he had just returned. After speaking with warmth of the general conditions, he said impressively, "The successful completion of the Panama Canal *depends on one man.*" If the measures admirably planned and carefully carried out by Colonel Gorgas fail, if there is a moment's relaxation, if the old epidemics recur, it will be impossible to find laborers, and the work will fail again as it did before.

Another opportunity for public usefulness in this country for which the training of the physician was peculiarly valuable was the career of the legislator. One had but to consider the few examples already mentioned of the various ways in which medical knowledge and skill were of value to the State, to realize how useful the education of a physician might be as a preparation for public life.

It was doubtless true that the development of the purely scientific branches of medicine together with the multiplication of specialties had resulted in a relative diminution of the number of family physicians in the old sense of the word, and had, in so far, limited the public influence which the old-fashioned general practitioner formerly exerted among his patients. But on the other hand, there had developed many wholly new problems which were calling the physician more directly into public life. If, perhaps, the wholesome influence of the family doctor was less felt in the community than it once was, yet the opportunities for public service had greatly increased.

The knowledge gained during the past forty years had taught us that we could accomplish far greater results by preventing disease than by attempting to promote recovery from that which had already started; it had taught us that a large proportion of the gravest maladies from which humanity suffered were acquired through our ignorance and carelessness and unclean habits; and with regard to many of these diseases, it had given us efficacious methods of prevention. Prophylaxis was the watchword of the day.

Dr. Thayer then spoke of the organization and aims of the American Medical Association, which was composed of a body of medical men united in the cause of truth and for the benefit of humanity—the deliverance of the public from disease. He asked why the recommendations of such an association should not have the force of laws, and said that it was owing to the lack of comprehension on the part of the public of the nature and aims of medicine and of physicians, citing a number of examples of such ignorance and of the opposition to measures of public health resulting therefrom. Many misconceptions, he said, arose from the strange atmosphere of mystery which so often surrounded medicine. From time immemorial the art of medicine had been connected in the mind of man with the supernatural and the divine. Medicine had been regarded rather as a matter of faith than as an art resting on a scientific basis. People spoke of their "belief" in this, that, or the other "system" of medicine, and on the basis of such "belief" recklessly handed over their bodies to some individual who asserted that his practice was based on a theory or system revealed as by inspiration to some fortunate mortal, perhaps yesterday, perhaps two hundred years ago. This blind faith in systems was not so far removed from the faith of the savage in the magic of his medicine man. This was partly the fault of physicians themselves who wrote prescriptions of little value, which they would not dream of taking themselves, letting the patient believe that they cured him of the transitory self-limited malady.

The same results could be achieved without misleading the patient one iota. It was perfectly possible to treat patients as we would be treated ourselves. It took a little longer; it involved a little more explanation; but the result was much safer and surer. Truth was as sacred a duty in medicine as anywhere else in life. As a matter of policy, as Cabot had pointed out, it was almost a necessity, for whatever might be true in other spheres of life, the doctor's lie was always detected.

Another widespread error to be combated was the common feeling of the public that the practice of medicine was purely and simply a trade. Viewed in this light the practitioner could but be often an object of suspicion. His methods and his word were doubted. The best part of his influence was gone. Most physicians, indeed, were obliged to depend on their fees, as most clergymen were obliged to depend on their salaries, for their daily bread. They must provide, not only for themselves, but often for their families. But there were very few physicians who entered into the practice of medicine with the idea of laying up wealth. There were happily exceedingly few to whom medicine was a trade. The man to whom the scientific and humanitarian aspects of medicine meant nothing; the man who practised solely for what he could make; the man who found no interest in medicine outside of that which he put in his pocket; that man was on a level with the conscienceless quack, and the sooner he left the profession the better for it and for the public. He deprecated the tendency, which he said existed among some otherwise honest and honorable men, to regulate the fees according to the means of the patient. Everyone should have a fixed maximal charge which should not be exceeded no matter what the wealth of the patient. He might often be obliged to charge less, but to demand exceptional recompense from the millionaire because of his wealth was to make medicine a trade.

Another duty of grave public import was the instruction of the public with regard to the necessary measures of prophylaxis in connection with infectious diseases. General

laws and sweeping public measures were of themselves insufficient to prevent the spread of such diseases as malaria, yellow fever, plague, cholera, and typhoid fever. It was only through the cordial and general cooperation of the practising physician with an enlightened public that efficient prophylaxis could be established. To combat the spread of preventable infectious diseases there were needed, he said, (1) an enlightened public, (2) a conscientious and united medical profession, each member ready to do his duty as an individual and especially to work in cordial cooperation with (3) central and local boards of health under the direction of trained sanitarians. The organization of all these measures depended, in the end, on the results of the individual efforts of physicians. The education of the public could be accomplished only by us; and it was our duty privately, publicly, day in and day out, to explain to the people the rules of self-protection.

Finally it was the physician's duty to seize upon the opportunity which might come to him as an individual to help forward the movement for better instruction in the schools of medicine by increasing the means for practical clinical experience. Dr. Thayer said that this could only be done by admitting students to serve as clinical clerks in the hospital wards. In these matters physicians must teach their nonmedical friends. When they realized that the hospitals needed medical students as trained assistants, as a part, really, of the staff; when they realized that the students needed hospital experience to make them capable physicians; when they realized that they owed this training to the physician in order to protect themselves and the public; then and then only would the old opposition to the instruction of students in the wards of hospitals disappear.

In conclusion, Dr. Thayer said: "The mention of these few opportunities for public service, opportunities which come to us all as physicians, should but impress on our minds the thought with which these remarks opened, namely that the physician is, from the very nature of his calling, essentially a public character. And however modest may be our field of work, our responsibility should always be before us. On our learning, on our progressiveness, on our alertness, on our honesty, on our fearlessness, on our perseverance, hang not only our own welfare, but that of the general public; in other words, that of our country, in much higher degree than we often realize. It is a heavy responsibility. Of much in the past we may be proud. There is much in the present on which we could improve. And the future? What shall that be? The answer lies with us."

Oration on State Medicine.—Dr. CHARLES HARRINGTON of Boston delivered this address, taking for his subject "States' Rights and the National Health." The movement now in progress for the establishment of national control of the public health was no new thing, he said. It began in 1871, when, at the annual session of the American Medical Association, resolutions were presented that steps should be taken to form a national health council, auxiliary to the association as a section on hygiene. At the next meeting, suggestion of an appeal to the Government to establish a national department of health to be supervised by the association met with objection, but the committee to which the resolutions presented at the previous meeting had been referred was continued as the Section on State Medicine and Public Hygiene. In 1874 a resolution was passed in the Section on State Medicine providing for an appeal to Congress, and a committee was appointed to report the next year a draft of a bill to establish a National Department of Health. At intervals, during all the years since elapsed, bills had been offered in Congress to the attainment of that end and had been duly pigeon-holed. The nearest approximation to a successful outcome of the agitation was reached in 1879, when, after the country had been aroused by the extensive epidemic of yellow fever which occurred in 1878, a national Board of Health was established, authorized to investigate all questions concerning the public health, to give especial attention to the subject of quarantine, and to concern itself with the project of establishing a permanent national health organization. This body made a number of important researches and inquiries, but in 1882 its duties were restricted to the investigation of cholera, smallpox, and yellow fever, and then the appropriations for its necessary expenses began to be withheld; and eventually, in 1893, its official existence was terminated. Since 1893 the nearest approach to a national health authority had been the Marine-Hospital Service, which in 1902 was by act of Congress changed in name to the United States Public Health and Marine-Hospital Service. This organization had its original inception in 1798, when twenty cents per month was deducted by law from the pay of all seamen on American vessels entering from foreign ports, to be collected by the customs authorities and expended in the districts where collected for the relief of invalid seamen in hospitals or elsewhere. The Act of 1902, creating the Bureau of Public Health and Marine-Hospital Service, was preceded by one which provided for the establishment of the Hygienic Laboratory for the investigation of contagious diseases and matters pertaining to the public health. The duties and activities of the Bureau of Public Health were many and varied. In addition to the work for the performance of which it originally was established, it had general supervision of marine and interstate quarantine, it inspected vessels and immigrants, conducted physical examinations for a number of branches of the Government, collected data concerning the incidence of the various diseases dangerous to the public health in all parts of the world, and published reports thereon, assisted the States in controlling, suppressing, and preventing epidemics, examined all establishments engaged in interstate commerce in vaccines, serums, and antitoxins, conducted researches in medical zoology, biological chemistry, pharmacology, bacteriology, and other fields of sanitary science, and engaged in other miscellaneous investigations. Once each year, and oftener if requested by not less than five State health authorities, the Surgeon-General was required by law to call the conference of State and Territorial Boards of Health for the consideration of matters pertaining to the public health, but the Government assumed none of the expenses of these annual conferences, either for travel or for subsistence. Every attempt thus far made to confer on the national Government any real power to supervise the national public health had found the Constitution in the way. The very first attempt made by the United States to enact a quarantine law met with opposition, and a section to empower the President to enforce quarantine was rejected by a two-thirds vote, as an interference with the States' police powers; but the provision to authorize the Government to assist the States in excluding yellow fever—for it was in consequence of an outbreak of that disease that the bill was introduced—was accepted. The doctrine of States' rights was an outgrowth of the ancient principle that an Englishman's house was his castle, but the individual had no right, Dr. Harrington said, to conduct himself and his house in such a way as to be a nuisance or a menace to the health of his neighbors; then the community would step in and restrain him. Similarly, a municipality which by neglect of sanitary observance had become a menace to the health of its neighbors would be taken in hand by the authorities of the State and compelled to pay due regard to the rights of its citizens as a whole. Why should the parallel end here? When a State neglected the health interests of its citizens and permit epidemic disease to rage without restriction, to the peril of the

health of its neighbors, should not the community of States have the right to interpose? It should, of course, but it had not. The regulation of the national public health was not delegated to Congress, and hence the right to be a national nuisance was reserved to the States. Dr. Harrington cited numerous instances in which the Federal Government had interfered with the rights of individual States, but no one complained, yet it carefully abstained from any suggestion of such interference when the matter was one of health. The pure food law, he said, was not primarily a health law, and from the standpoint of health it was not needed, but it was enacted in order to load the general government with work which many of the individual States were unwilling to undertake. We were a commercial nation, he said, and human life and freedom from the preventable diseases of mankind were no part of foreign or domestic trade, therefore the Government concerned itself little with them. It was, however, otherwise with the diseases of plants and of the lower animals, for the products of the fields and farms and cattle ranges brought us great wealth. Hence Washington spent millions annually on plant and animal physiology and pathology. It was good business to expend thousands and tens of thousands against sheep scab and swine cholera, but the eradication of human tuberculosis appeared to be unworthy of national effort, if it entailed national expense. The duty of medical men in this matter was obvious. They should take the lead in arousing an educated public interest in the national health. Of great value, as shown in the agitation for the law relative to foods, for the establishment of sanatoria, and for ordinances against the spitting habit, were popular lectures, magazine articles, and the sympathy of the press. Two years ago there was inaugurated at the Harvard Medical School a series of free public lectures, given on Saturday evenings and Sunday afternoons for four months, mainly on preventive medicine. The first series was a most gratifying success; the second so largely attended that at times more people were turned away than succeeded in securing places. The chief result was a widespread interest in public hygiene and a marked strengthening of the cordial relations which ought to exist everywhere between the profession and the public. The example set in Boston had been followed elsewhere with like results, and the more the habit spread the sooner would the advocates of a federal health administration see a successful outcome.

Whether the proposed service should take the form of a department represented in the Cabinet or of a division of an existing department with a commissioner for a chief was of no very great importance, although there was some very obvious objections to the suggestion of a separate department, which could hardly apply to that of a division; but department or division, it could properly have as its nucleus the present Bureau of Public Health and Marine-Hospital Service, to which should be added various existing bureaus scattered about under different departments—some not duplicating the work of others—and additional bureaus to be created. Its head should be charged with advisory powers in relation to other departments and to the States, and with supervisory and executive powers in matters pertaining to his own bureaus. Inasmuch as no one man could be expected to conduct so great an establishment with only the advice of his bureau chiefs, and inasmuch as the cordial cooperation of all the States would be absolutely essential to satisfactory achievement, the head of this department or bureau should have a national council consisting of one delegate from each State, appointed by the Governors or State boards of health for a term of years. Such a council should be composed of men of recognized standing in medicine, engineering, or other branch of learning which would be of assistance. It should be called together at least once each year and as much oftener as might appear to be necessary, and the expenses of each such meeting should be borne by the Government rather than, as now is the case with the annual conference of the State boards of health with the Surgeon-General of the Public Health and Marine-Hospital Service, at the expense of the States or of the delegates themselves. At each meeting the subject of the national health should be discussed and proposals for future work should be made and considered. Even though at times the meetings might not appear to be of great scientific value, at least they would serve to promote the cordial feeling that the individual States formed a part of the administration and exercised a proper influence.

SECTION ON PRACTICE OF MEDICINE.

DR. C. F. HOOVER OF CLEVELAND, OHIO, IN THE CHAIR.

Tuesday, June 2—First Day.

Chairman's Address: Paroxysmal Hemoglobinuria.—Dr. C. F. HOOVER of Cleveland, Ohio, made this address. He reported the cases of two young men, twenty-five years of age, both apparently in good health. One had attacks of paroxysmal hemoglobinuria for five years, while the other had these attacks but for sixteen months. These paroxysms were confined almost wholly to cold weather. In the one who seemed to have less sensitive blood they occurred usually during the time from October to May. The other patient was extremely sensitive to cold and had attacks even during the summer months if there was any cold weather; he had even had them occur in July. The attacks could be brought on by placing one foot in a vessel containing cold water. The time usually required to bring them on was about fifteen to twenty minutes. They placed the foot in up to the middle of the leg; the water was about 15° C. Soon the foot and leg would begin to feel as though they had been pounded. Then beginning with chills or rigor there would follow cyanosis of the lips and finger nails. In one patient there would appear macules, and in the center of each would be found a pustule; this was the only cutaneous manifestation. During the time of the chill there would be no elevation of temperature; with the beginning of the chill there would be a lowered temperature of about one degree per rectum; then the temperature would begin to rise, gaining its maximum about one and a half hours after. When the foot was placed in cold water the temperature was 98.5° F. At the time the foot was removed it would be 97.5° F. Following a chill which would last about twenty minutes there would occur this rise in temperature and in the course of an hour and a half it would register about 103° F. This temperature lasted a varying period of time, sometimes as long as three hours. The black urine was obtained often before the elevation of temperature occurred. They found that when the patients passed urine directly at or during the latter part of the chill, it was dark. Soon the urine was the shade of burgundy red. There was nothing found in the urine that was abnormal but oxyhemoglobin and some albumin. There were no red cells at all, no casts, nor blood pigment. When symptoms developed during the febrile stage, there was noted also some tenderness over the spleen. The problem that confronted them was, what had happened to these patients; how could they account for this hemoglobinuria? When the foot was placed in cold water and blood withdrawn from a vein, pink serum was found; before it had been straw colored. They demonstrated that this hemolysis occurred while the patient was chilled; it probably began before the patient was chilled. The hemolysis was completed before elevation of temperature began. They found that during the attack

the maximum blood pressure was unmodified and remained the same during the attack. The quantitative analysis made of urea, the nitrogen, the phosphates, chlorides, etc., was found to be the same before, during, and after the attack; there were absolutely no variations. He demonstrated the fact that one could not get hemolysis without the employment of cold.

Clinical Manifestations of Cardiovascular Disease.—Dr. Frank A. Jones of Memphis, Tenn., read this paper. He said that to the pathologist arteriosclerosis had been the enigma of medicine. There was an hypertrophy of an organ here, and an atrophy of an organ there, as for example the contracted kidney and the enlarged heart. They met with obliteration of an artery in one place, and contraction and dilatation in another. The old adage that a man was as old as his arteries needed a thorough revision commensurate with the age in which they were living. Arteriosclerotic patients he said were barometers of temperament. He believed that many a case of angina cerebri masqueraded as apoplexy and paralysis. Acute hepatic colic in the absence of gallstones might be angina hepatica. Khrel struck the keynote when he said that in his clinical experience and in his post-mortem findings, arteriosclerosis had its starting point in the splanchnic blood-vessels. When they came to consider the therapeutic measures resorted to he knew of no disease in which they were more abused. Cardiovascular tonics were given as injudiciously as digitalis in cardiac vascular disease. Not every case demanded the nitrites or the iodides. The all-absorbing question now was, how was the blood pressure? It had almost become a fad. Various instruments of precision had been extolled in testing pressures. The trained clinician could use these instruments of precision when they would become valuable adjuncts; but in the hands of the inexperienced, the average physician, they frequently became instruments of imprecision and prejudiced him in his findings. He believed in the use of these instruments of precision, but cautioned them not to forget the old reliable instruments, the fingers, eyes, ears, which God had given them.

Cardiac Aneurysm, with a Report of a Case Associated with Mediastino-Pericarditis.—Dr. James B. McElroy of Memphis, Tenn., read this paper. He said very little attention had been given this subject in the text-books. In the general literature of to-day three different conditions were spoken of under the term aneurysm of the heart, viz., (1) aneurysmal dilatation of the coronary arteries, which might be multiple or single, which might vary in size from a mustard seed to a cherry, and which was due to sclerosis or embolism of these vessels; (2) aneurysm of the valves of the heart, by which was meant a cavity in the substance of the valve, containing pus or other inflammatory products, clotted blood, or debris; (3) aneurysm of the cardiac wall. The first two conditions were almost wholly of pathological interest, but their inclusion under the term aneurysm of the heart had somewhat confused the statistics upon the subject. It was to the third condition, or aneurysm of the cardiac wall, that he referred in his paper. Only two such cases had been contributed to general literature by American writers during the thirteen years prior to 1904. In 1867 Pelret collected 87 cases from the world's literature up to that time. There were probably now in the literature reports of 300 cases. Dr. McElroy then gave a complete report of a case which was a noteworthy one in its excellent representation of this type of case. At autopsy there was shown springing from the apex of the left ventricle anteriorly a large dilatation about the size of an orange. There was a communication with the left ventricle which was marked by a well defined fibrous ring two inches in diameter. The width of the swelling at its greatest diameter was five and one-half inches, in depth three inches. The sac was formed by roughened endocardium and myocardium. The cavity was filled with dark clotted blood. These aneurysms varied in size, from that of an English walnut to the size of a child's head. They were usually single but they might be multiple. The opening into the cavity of the heart was usually large, but it might be small, rendering the aneurysm sacular. The symptoms might be any one of those characteristic of the three clinical groups of myocardial disease, viz., those in which death occurred without previous indications of heart trouble, and might be sudden; second, cases in which there was arythmia, cardiac asthma, etc.; third, cases with general arteriosclerosis and hypertrophy and dilatation of the heart. It was surprising how few cases terminated in rupture of the sac. By far the most frequent termination was from cardiac insufficiency from myocarditis.

Dr. Robert B. Preble of Chicago presented a boy with an aneurysm of the heart. The boy was shot, the bullet entering a little to the left of the sternum. There were at first no cardiac disturbances, but subsequently there developed an aneurysm of the outer portion of the left ventricle.

Dr. James B. Herrick of Chicago called to mind the case of a colored man, thirty years old who, at autopsy, presented in addition to valvular trouble a mediastinal pericarditis and a chronic fibrous myocarditis. In one of the areas of cardiac softening and near the tip of the left ventricle had occurred a rupture of the myocardium, evidently preceded by an aneurysmal dilatation; this rupture instead of occurring directly into the open pericardium occurred in the weakened spot between the two adherent surfaces of the pericardium. This little sac of pericardium at the time of death had reached the size of a goose's egg.

Dr. Butler of Chicago said that the close relationship that existed between fibrous myocarditis, pericarditis, and aneurysm had been well recognized. He recalled the case of a child nine or ten years of age whom he had under observation a few years ago. This child had a congenital pulmonary stenosis which was complicated by an acute endocarditis involving the pulmonic valve. At autopsy there was noted a distinct bulging of the anterior portion of the conus, the bulging being as large as a pigeon's egg. There had apparently been an inflammatory condition of the conus, a septic endocarditis which in conjunction with a fatty degeneration had resulted in this bulging at this point producing an aneurysm in this child.

Dr. James B. McElroy of Memphis, Tenn., believed that the only possible time for diagnosing these conditions was when the aneurysm was favorably located. He had observed or seen reported in the literature that out of 90 cases diagnosed postmortem, only one had been diagnosed antemortem.

Clinical Aspects of Tumors of the Mediastinum.—Dr. Frank Smithies of Ann Arbor, Mich., read this paper. The records of hospitals and post-mortem rooms showed that mediastinal neoplasms, whether primary or secondary, were uncommon. Of more than 7,500 autopsies upon patients dying from all causes, at the Marine Hospital, Cronstat, one in fifty exhibited mediastinal growths. It had been estimated that one medical patient in ten thousand showed mediastinal tumor of some form. Of more than 25,000 general hospital patients at the University of Michigan Hospital, there had been perhaps a dozen cases of tumor of the mediastinal structures. It was extremely interesting, therefore, that within the past year and a half they had under observation four cases of mediastinal growths, and, in addition, two cases where the diagnosis was suspected. Perhaps this increased ratio was due to the increasing perfection of clinical aids in the examination of patients. After briefly reviewing the anatomy of the mediastinum, he said that it could be readily seen that the symptom complex presented by any class of mediastinal growths was largely dependent upon the size and position of such growths. The great majority of these tumors in this region arose in the anterior space of the inferior division. They were most commonly car-

cinoma, sarcoma, or lymphoma, and had their origin in thymus remnants, lymph glands, and connective tissue. In the middle space, the primary focus was generally the lymph tissue. The tumors in this region might be of almost any variety. In the posterior space primary tumors were relatively uncommon. They might arise from lymph tissue, from the lung or its adnexa, or from the esophagus. In general mediastinal neoplasms produced signs and symptoms as the result of the pressure they exerted upon the bony framework, blood-vessels, or nerves or air-containing tissues. The four cases which furnished the material for the communication were interesting from many standpoints; one of them, a case of chronic cyanosis with arythmia, was unique. The diagnosis in all instances was presumptive, in so far as absence of post mortem was concerned, but sufficient evidence was at hand to make the conditions reasonably certain. All the patients were adults. There were three males and one female. The youngest was forty-three, the oldest sixty-seven. They came to the hospital with such ailments as heart disease, asthma, chronic bonchitis, Bright's disease, laryngeal obstruction. Three of the patients appeared to have affections primary in the thorax. In the female the process was evidently secondary. Two patients had rapidly-spreading, malignant growths, with death supervening within less than a year after they came under observation. In the remaining cases, the neoplasms were apparently of slow growth, and the patients had been affected for some time. A report of these four cases in detail followed.

Dr. Thomas D. Coleman of Augusta, Ga., said that the condition was a very rare one, especially among the negroes. They were very subject to syphilis, tuberculosis, and adventitious growths in general, but he had never seen a single case of mediastinal tumor occurring in a full-blooded negro. He had seen two cases occurring in mulattos; the others that he had seen were whites and males. The ages were anywhere between thirty and sixty years. In one case there was cancer of the mediastinum; the diagnosis was confirmed at autopsy. In another case, not verified by autopsy, there was a distinct paralysis of the left vocal cord which was suspected to be the result of a gumma. This patient was placed upon specific treatment, and he got well. Whether a correct diagnosis had been made or not, he said he was not prepared to state.

Dr. Alexander Lambert of New York spoke of one particular case that had puzzled him years ago, and which turned out to be a sarcoma occuring at the junction of the vena azygos major and the superior vena cava. The pressure symptoms produced were very peculiar; when the patient was lying down he was blue from the clavicles up, the rest of the body being normal in color. But when the patient sat up he would be blue between the knees and the cavicle, the rest of the body being normal in color. The legs remained white at all postures. It seemed that this tumor must have acted as a ball valve. In working out the circulation of the chest, he agreed that the tumor was at the point mentioned. It was a primary sarcoma of the right ventricle of the heart. Dr. Lambert said that he had seen quite a number of mediastinal tumors at Bellevue Hospital, and he had been struck by the fact that the symptoms produced were paroxysmal in character. There would occur a cough, like whooping cough, without apparent reason or cause for the excitation. The pain and dyspnea occurred in paroxysms; the whole thing would come on and go without any reason, and apparently in spite of what they did or because of what they did.

Dr. Robert H. Babcock of Chicago told of a case of mediastinal tumor that he had seen one year ago in the interior of Wisconsin, and the diagnosis of sarcoma of the mediastinum was substantiated post-mortem. The patient had been treated for pulmonary tuberculosis, and this illustrated the fact that a physician could mistake such a condition for pulmonary tuberculosis when there was a distinct tumefaction of the front of the chest, instead of the depression which was so characteristic of the phthisical habitus. The upper portion of the chest was bulging, and there were signs of intrathoracic pressure marked. The patient had also been treated for syphilis. Intrathoracic disease could not always be diagnosed by the physical signs alone; one must take into consideration the symptomatology and the history as well.

Clinical Observations on Absolutely Irregular Hearts.—Dr. W. H. Hewlett of San Francisco read this paper. The characteristics were: (1) Absence of normal auricular contractions; (2) irregularity itself; (3) permanency. The evidences of the absence of normal auricular contraction were to be found at the apex, the jugular pulse, the murmur of mitral stenosis, the esophageal cardiogram, and the electric cardiogram. In the mitral stenosis murmurs there was presystolic accentuation in regular hearts; whereas, in irregular hearts there was no presystolic accentuation. It was important that physicians should bear in mind the fact that in absolute irregular hearts they must not expect presystolic murmurs. Dr. Hewlett gave an analysis of 30 cases, in 24 of whom the ages were given. Five were below 40 years, 14 were between the ages of 40 and 60; while five were above 60. In 10 the lesion was a mitral insufficiency alone; in 5, a mitral insufficiency plus a stenosis; in 2, a mitral stenosis alone; in 3, an aortic lesion alone; and in 1 there was an adherent pericardium. With regard to the etiological factors, rheumatism occurred in 12, alcoholism in 10, hyperthyroidism in 2, chronic nephritis in 1, and arteriosclerosis in 1. About one-third of the patients died or were permanently disabled.

Malignant Septic Endocarditis.—Dr. John A. Witherspoon of Nashville reported the findings in two such cases. The patients were under observation last year. One was a case of septic malignant endocarditis following a carbuncle, which first developed on the back of the neck. The other was a case of surgical kidney, in which there were no appearances of endocarditis whatever until after the removal of the kidney. Then, in a short time, a malignant type of endocarditis developed and the patient died in a few days. With regard to the surgical kidney case it had occurred to him that the energy necessary in handling the kidney so deeply situated, the posterior operation having been done, might have caused an expression of the poison into the blood-vessels, thus causing the carrying of a septic embolus to the heart.

SECTION ON SURGERY AND ANATOMY.

Tuesday, June 2.—First Day.

Introductory Remarks by the Chairman.—Dr. Rudolph Matas of New Orleans said that no more fitting manner of opening the Section on Surgery and Anatomy could be found than by paying tribute to the memory of the great American surgeon whose labors had ceased during the past year—Dr. Nicholas Senn. Surgeon, teacher, author, world-wide traveler, writer, beloved and respected by all who knew him, his name was destined always to remain bright in the annals of surgery of the country and of the world. His removal from a sphere of useful activity was a deplorable event in the annals of surgery.

Results of the Transplantation of Blood-vessels and Organs.—Dr. Alexis Carrel of New York read this paper. He demonstrated a series of lantern slides which showed how little scar remained after the section and reunion of the vessel by the end-to-end method of ligature which he had devised. Some of these slides were taken from artries in which the suture had been placed more than a year ago, and the line of union in almost all cases was invisible. The important points to which he called attention were as follows: The substitution of a segment of artery or vein, supposedly diseased, by fresh arterial or venous segments of similar size, if taken from an animal of the same species, was successful. If a segment of vein were transplanted into an artery the vein usually adapted itself to

the new arterial function. If kept in sterile tubes and in a temperature just above freezing it had been shown without any possibility of doubt that segments removed either from living animals or recently dead human bodies could be used for bridging defects even after they had been kept for a month. He said that in transplanting parts it was necessary to use care to deal with the mass of tissue which was supplied by certain main trunks. Obviously, if the mass to be transplanted derived its arterial supply from main arterial trunks which did not become the subject of section and suture the parts would slough. To demonstrate this, he showed a photograph of a dog in which the ear, side of the neck, glands, and accompanying tissues had been successfully transplanted because they were supplied by the carotid.

Physiologic Aspects of Blood-vessel Surgery.—Dr. C. C. Guthrie of St. Louis read this paper. He described in some detail the technique as modified by himself and Carrel. Aside from the general proposition that the intima should always be perforated, and that needle and thread in strict proportion to the size of the blood-vessels should be employed, he deemed the most important consideration to lie in the extreme gentleness of handling the tissues and the great care taken in protecting them from drying. Any light pair of forceps suitably protected could be employed without injury, and paraffin oil in his hand had proved more satisfactory than vaseline. He stated that in his most recent work none of the so-called physiological salt solutions were employed. Gentle pressure exerted at the line of anastomosis always stopped any slight hemorrhage which might occur around the sutures. There must of necessity be more or less fibrin deposited at the anastomotic point due to the incomplete juxtaposition of the ends, and more particularly through the presence of the stitches which constituted so much foreign material. The blood platelets which provided the thrombogen had long been known to flock to the region of an irritant, and calcium being present in abundance in the plasma the conditions were most favorable to clotting. As to the size of the vessels which it was possible to operate upon satisfactorily, failures should not occur in those having a diameter of 2 mm. In smaller vessels there was apt to occur an amount of clotting which would appreciably diminish functional activity. The use of a non-essential vein, or of cold storage segments, or those which had been preserved in formaldehyde was an important and interesting side issue in the technique which was empirically known to be successful. The transplantation of limbs might be considered an established fact, because it could be done without having gangrene develop. Heads had been transplanted after removal from one dog into the neck of another, and it was shown that such heads preserved for many hours under the stimulus of an alien circulation certain bulbar and cerebral functions. The cerebral circulation was interrupted for twenty-nine minutes. The author believed that the chief point of difficulty in the transplantation of such organs as the kidney lay in the fact that up to date it had been necessary to wash them out with so-called physiological salt solution in order to prevent the contained blood from clotting. This process had probably advanced to a point of appreciable danger at the end of forty minutes. He had found it difficult to preserve the normal histology of transplanted kidneys after they had been washed out, even though circulation had been reestablished without postoperative reaction. In order to prove this point, which he considered a most important one, he had tried the experiment of simply injecting 10 c.c. with so-called physiological salt solution, and had found that it killed the animals. Either some less injurious form of irrigation must be devised or the time of operation must be materially shortened before great progress could be made in the transplantation of kidneys and similar tissue masses.

Review of Recent Contributions on the Surgical Treatment of Aneurysm by the Intrasaccular Method (Endoaneurysmorrhaphy).—Dr. Rudolph Matas of New Orleans read this paper. He said that up to June 1, 1908, eighty-five cases had been reported. They had been contributed by forty-nine American surgeons and three foreign surgeons. Six years ago only five cases had been operated upon by this technique, the rapid progress of which had been gratifying in that it suggested that the operation was based upon sound surgical principles. Most unfortunately there had been a very great misunderstanding and misrepresentation of the technique in Europe, except in Spain and Italy, where it was not at all understood. There were seventy-eight recoveries, but it was only just and fair to the future of the operation to state that in two cases only could death in any sense be attributed to the operation itself. No less than four surgeons had attempted to use the technique in the treatment of aneurysms of the abdominal aorta. This laid a mortality of 2.3 per cent. to the operation proper. Very important details were being brought to light because of the heretofore neglected study of the interior of the aneurysmal walls. The fundamental principle of the operation was that the endothelial lining is analogous to and continuous with the serosa. He referred to Scarpa's law, and stated that it was challenged by the modern operation and also by the use of the suture. Hemostasis, which was essential to success, increased in difficulty as the aneurysm approached the great vessels of the trunk. Proximal and digital compression of the main trunk was usually valueless and dangerous, because of the presence of the collateral branches which opened very near the sac. Thus abdominal section for the control of the iliacs was usually indicated in femoral aneurysms. Before using the obliterative technique upon aneurysms of the carotid it was wise to study the effect of temporary interference with the cerebral circulation.

Successful Ligation of the Innominate Artery.—Dr. W. B. Burns of Memphis read this paper. He presented a critical review of the status of this operation, dividing the reported cases in five groups. His was the only successful case of ligation of the innominate artery alone where the vessels were diseased. In this particular instance there was a clear syphilitic history. The ligature was made with heavy silk, superficial suppuration ensued, and on the thirtieth day the ligature was removed. The patient, a young negro man, was now, ten months from the date of operation, in perfect health.

Dr. J. E. Sweet of Philadelphia said it was singular that until the last five years nothing had been done in this work, although it had been begun as early as 1657, when transfusion was first practised. He said that while the suture method might be all right, for the permanent work he preferred to use any form of small cylinder by which the accurate juxtaposition of the intima could be relied on, because it was more rapid and therefore more suited to laboratory experiments.

Dr. J. F. Binnie of Kansas City said that he considered the use of catgut in arterial work exceedingly dangerous.

Dr. Danna of New Orleans described seven cases of aneurysm in which he had used the Matas technique. He said that a general misunderstanding existed among the profession as to the necessity of drainage. If the sac was entirely lined by serosa none was indicated. Fusiform aneurysms, contrary to the usual belief, were not generally spindle-shaped, but were sacciform.

Dr. George Crile of Cleveland said the technique of Carrel and Guthrie was eminently practical.

Dr. Matas, in closing, said that Dr. Binnie's objection to the use of catgut resulted from a misconception of the form of catgut which he, Matas, had advocated. Plain catgut would not do, but fine chromic gut, either No. 0 or No. 1, had been used with admirable results.

(To be continued.)

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

FLORIDA BOARD OF MEDICAL EXAMINERS.

Ocala, April 13 and 14, 1908.

ANATOMY.

1. Describe the humerus.
2. Describe the hip-joint.
3. Give a general description of the lungs.
4. Locate and describe the spleen.
5. What is the diaphragm.
   Name the principal openings in the diaphragm.
6. What is the circle of Willis.
7. Describe the muscles of the eyeball and give their nerve supply.
8. Describe the pons Varolii.

PHYSIOLOGY.

1. What is the mode of production of heat in the body.
2. State the function of the retina.
3. What do you understand by blood pressure?
4. How is the sensation of pain produced?
5. Describe the physiology of rectal feeding.
6. How are the vocal sounds produced?
7. What are the functions of the pancreas?
8. Describe the pons Varolii.
9. Describe the normal heart sounds.
10. Name the solids in the urine and state the approximate amount of each voided daily by an adult.

SURGERY.

1. Define and differentiate between bacteria, ptomaines and toxins. Name three antiseptics which will destroy pyogenic bacteria.
2. Describe, briefly, inflammation, cellulitis, suppuration and gangrene.
3. Give the treatment of syphilis, beginning with the primary lesion and following it out to a cure.
4. Describe synovitis, arthritis, and ankylosis.
5. Name five varieties of tumors, and differentiate between a fibrous and a fatty tumor.
6. Give the diagnosis and treatment of fracture of the neck of the femur.
7. Name the various dislocations of the shoulder-joint.
8. Give the usual cause, diagnosis, and treatment of hip-joint disease in children.
9. What symptoms would be diagnostic of an abscess of the antrum of Highmore? How would you enter this cavity for the purpose of drainage and irrigation?
10. How would you make a differential diagnosis between alcoholic, apoplectic, and uremic coma?

GYNECOLOGY.

1. Why are girls never hysterical before puberty?
2. Explain difference between hysteria and catalepsy.
3. Explain symptoms and determine a positive diagnosis of retroversion of the uterus.
4. What is menorrhagia? Explain causes and outline treatment.
5. Give in full your treatment of gonorrheal endometritis.
6. What are the immediate and remote results of laceration of cervix uteri not repaired?
7. What are the most common kinds of ovarian tumors, and which attain to great size?
8. What conditions justify ovariotomy?
9. Give symptoms and treatment of cystitis.
10. Give symptoms and treatment of carcinoma mammæ.

THERAPEUTICS.

1. Acids. Into what classes divided, and indications for their use?
2. Scilla. In what class of remedial agents does it belong? Officinal preparations and doses of the same.
3. Digitalis. State when in your opinion it is contra-indicated, and name the agents with which it is incompatible.
4. Give child (1 year), and adult, dose of acetanilid, tincture of opium, tincture of gelsemium.
5. Strophanthus. Officinal preparation and dose. In what class of cases used.
6. Anthelmintics. Name the ones most generally used, and in what doses.
7. Opium. Name its alkaloids. Outline treatment in a case of acute opium poisoning.
8. What are antidotes, and into what classes would you divide them?
9. Antipyretics. For what do you use them? Name the ones you generally use.
10. Name a drug which when taken internally causes contraction of the pupil of the eye, and one when applied locally.

OBSTETRICS.

1. Describe the anatomic differences, not including the sexual organs, between the male and the female figure.
2. Give an anatomic description of the genital organs of the female and state the function of each organ.
3. On what signs may a diagnosis of occipito-posterior position be based?
4. Make a diagnosis of breech presentation and state the principles that should govern its management.
5. Mention the most reliable signs of pregnancy before the fourth month.
6. What conditions justify the induction of abortion? Mention the methods that may be employed.
7. What is pathology of puerperal mastitis? State how puerperal mastitis should be treated.
8. Describe the nature, causes, and treatment of puerperal eclampsia.
9. Define version, mention its varieties and describe its performance.
10. What is ectopic pregnancy? Mention the dangers of ectopic pregnancy, and state how it should be treated.

CHEMISTRY.

1. State the law of multiple proportions.
2. Give the formula for ammonia, and give physical and chemical properties of ammonia water.
3. How does nitric acid act on animal matter, and what are its properties generally?
4. What acid is used in preparing sulphite salts?
5. Describe three reliable tests for albumin in the urine.
6. Give antidotes for poisoning by match heads.
7. Describe treatment for a case of poisoning by rat poison.
8. Describe treatment for poisoning by bichloride tablets.
9. What common antidotes are usually found around the house for caustic potash poisoning?
10. What is the dose of apormorphine, how administered and for what purposes?

ANSWERS TO STATE BOARD EXAMINATION QUESTIONS.

FLORIDA BOARD OF MEDICAL EXAMINERS.

Ocala, April 13 and 14, 1908.

PHYSIOLOGY.

1. *Heat is produced in the body,* by: (1) Muscular action; (2) the action of the glands, chiefly of the liver; (3) the food and drink ingested; (4) the brain; (5) the heart; and (6) the thermogenetic centers in the brain, pons, medulla, and spinal cord.

2. *The function of the retina,* is: To receive the image of objects and cause nervous stimuli to convey the same to the brain.

3. By the term *blood pressure* is meant the pressure on the blood due to (1) the ventricular systole, (2) the elasticity of the walls of the arteries, and (3) the resistance in the capillaries.

4. Pain is due to excessive stimulation of the sensory nerves, including those of special sensation, particularly those concerned with touch and temperature. It is, however, believed by some that pain is a distinct sensation, independent of other sensations.

5. "That all mucous membranes are capable of absorbing certain materials from their surfaces and passing them into the blood-vessels or lymphatics has long been recognized; but it is only of comparatively recent years that this knowledge has been applied extensively to the purpose of nourishing patients by means of the rectum, and the fact is now established that sufficient aliment may be absorbed from the mucous membrane of the rectum or sigmoid flexure alone to sustain life for a considerable period, amounting in some cases from four to seven weeks. Moreover, the rectum may be utilized for accessory feeding for many cases in which the stomach is able to digest some food, but not in sufficient quantity to prevent emaciation. Whenever rectal food enemata are employed certain principles should be observed: (1) The rectal surface must be cleansed from all mucus and feces. (2) The irrigation of the rectum should be allayed as far as possible. (3) The quantity and quality of food thus administered should be so regulated as to avoid exciting peristalsis, and yet allow of the complete absorption of one injection

before another is given." — (Thompson's *Practical Dietetics.*)

6. The *Vocal Sounds are produced* by an expiratory blast of air being forced through the narrow chink between the true vocal cords. The current of air sets these vocal cords in vibration; and these vibrations are communicated to the air in the upper air passages. The pitch of the sound produced depends upon the rapidity with which the vocal cords vibrate.

7. The *functions of the pancreas* are: (*a*) The secretion of the pancreatic juice, which (1) changes proteids into proteoses and peptones, and afterwards decomposes them into leucin and tyrosin; (2) converts starch into maltose; (3) emulsifies and saponifies fats; and (4) causes milk to curdle.

(*b*) The manufacture of an internal secretion.

The *ferments secreted by the pancreas* are: Trypsin, amylopsin, steapsin, and a milk-curdling ferment.

8. The *physical properties of blood*: Fluid, somewhat viscid, red, specific gravity from 1055 to 1062, alkaline reaction, saltish taste, characteristic odor, variable temperature (average about 100° F.).

The *constituents of the blood* are plasma and corpuscles. The *plasma* consists of water and solids (proteids, extractives, and inorganic salts). The *red corpuscles* consist of water and solids (hemoglobin, proteids, fat, and inorganic salts). The *white corpuscles* consist of water and solids (proteid, leuconuclein, lecithin, histon, etc.).

The *red blood corpuscles* are biconcave discs, about 1-3200 of an inch in diameter; they are nonnucleated, and there are about 4,500,000 or 5,000,000 of them in each cubic millimeter of blood. They are elastic and soft, and their shape is changed by pressure, but is promptly regained on the removal of the pressure. Their color is yellowish. They contain hemoglobin.

Their *function* is to carry oxygen from the lungs to the tissues.

The white blood cells are spheroidal masses, varying in size, having no cell wall, and containing one or more nuclei; there are about 7,000 to 10,000 of them in each cubic millimeter of blood. They differ much in appearance, and are divided into (1) small mononuclear leucocytes, or lymphocytes, (2) large mononuclear, (3) transitional, (4) polynuclear, or polymorphonuclear, or neutrophile, and (5) eosinophile. They are all more or less granular, particularly the last two varieties named. They are probably formed in the spleen, lymphatic glands, and lymphoid tissues. Their fate is uncertain; it has been asserted that they are converted into red blood cells; they play a part in the formation of fibrin ferment; they are sometimes converted into pus cells. Their functions are (1) to serve as a protection to the body from the incursions of pathogenic microorganisms; (2) they take some part in the process of the coagulation of the blood; (3) they aid in the absorption of fats and peptones from the intestine, and (4) they help to maintain the proper proteid content of the blood plasma.

There are also *platelets*, which are very small, colorless, irregular shaped bodies; they are about one fourth the diameter of a red corpuscle. Their function is not determined; it is possible that they take some part in the coagulation of the blood. In number they vary from about 200,000 to more than 500,000 in each cubic millimeter of blood.

Plasma conveys nutriment to the tissue; it holds in solution the carbon dioxide and water which it receives from the tissues, and takes them to be eliminated by the lungs, kidneys, and skin; it also holds in solution urea and other nitrogenous substances that are taken to and excreted by the liver or kidneys.

10.

SOLIDS IN THE URINE.	VOIDED PER DAY.
Organic—	
Urea	about 500 grains.
Uric acid	about 10 grains.
Hippuric acid	about 6 grains.
Creatinin	about 12 grains.
Extractives	about 150 grains.
Inorganic—	
Sodium chloride	about 150 grains.
Phosphoric acid	about 37 grains.
Sulphuric acid	about 24 grains.
Oxides of calcium, magnesium, sodium, and potassium	about 20 grains.

SURGERY.

1. *Bacteria* are unicellular vegetable organisms, nonnucleated, composed of protoplasm, exist nearly everywhere, and *may be* the cause of disease.

Ptomaines are alkaloids produced by the action of bacteria on dead animal matter.

Toxins are nonalbuminous, poisonous substances, excreted by bacteria.

Three antiseptics which will destroy pyogenic bacteria:—bichloride of mercury, carbolic acid, mercuric iodide.

7. The *various dislocations of the shoulder-joint* are:—(1) Subcoracoid—forward, inward and downward. (2) Subglenoid—downward, forward, and inward. (3) Subspinous—backward, inward, and downward. (4) Subclavicular—forward, inward, and upward.

8. Hip-joint Disease in Children.—The *usual cause* is tuberculosis.

The *early symptoms of the disease* are: Night cries; lameness in the morning; a slight limp; tendency to become tired on slight exertion; wasting; spasm; pain; swelling; and deformity (either real or apparent).

The *diagnosis* is to be made from: (1) *Growing pains*, which are not increased by movement. (2) *Sacroiliac disease*, in which the pain is not increased by movement of the hip-joint. (3) *Congenital dislocation of the hip*, in which there is great mobility of the joint, and no pain on pressure. (4) *Spinal caries* and *Psoas abscess*, in which there are evidences of disease of the vertebræ; and the pus is located in the groin, external to the femoral vessels. Other conditions from which it may be necessary to diagnose hip-joint disease are: Infantile paralysis; lordosis, from rickets; and rheumatism.

Treatment: Complete rest in bed; extension, using just enough weight to prevent the muscles from contracting; fresh air, tonics, and good food; immobilization by means of plaster-of-Paris dressing; iodoform injections. If these fail, resection of the joint may be necessary.

9. Abscess of the antrum of Highmore, may be *diagnosed* by: (1) The presence of pus flowing over the middle turbinate bone, when the patient has his head bent downward and forward; after being wiped away, pus still continues to flow. (2) Transillumination will show a dark shadow. (3) Aspiration through the canine fossa.

The antrum can be entered for the purpose of drainage and irrigation: (1) through the canine fossa; (2) through the socket of the first or second bicuspid tooth.

10. In *alcoholic coma*:—The patient can generally be aroused; the coma is not, as a rule, complete; the face may be flushed; the pupils are normal or dilated; the respirations are normal in frequency, but deep; the skin is cool and moist, and the body temperature may be below normal.

In *apoplectic coma*:—There is generally paralysis of the head and upper limbs; and in left-side lesions there may be aphasia; the pulse is slow and full; the respirations are at first slow, regular, and stertorous, later on becoming of the Cheyne-Stokes type.

In *uremic coma*:—The coma is deep; the pulse slow; the respirations frequent and irregular; the urine shows the presence of albumin and casts, with a diminished output of urea; there may be a urinous odor to the breath.

GYNECOLOGY.

4. *Menorrhagia* is a condition characterized by excessive loss of blood during the menstrual period.

Causes: Tumors, uterine displacements, endometritis, subinvolution of the uterus, lacerations and cystic degeneration of the cervix, tubal and ovarian diseases.

Treatment: Remove the cause, if possible; treat abnormal conditions that are present; vaginal douches, tampons, and curettage have all been recommended; also ergot, hamamelis, hydrastis, and virburnum prunifolium.

5. The *treatment of gonorrheal endometritis* consists in dilating the cervix, curetting the uterus, washing out the uterine cavity with an antiseptic solution, and swabbing with carbolic acid or tincture of iodine.

6. Laceration of the cervix may cause hypertrophy, elongation, sclerosis, cystic degeneration, or carcinoma of the cervix; subinvolution, or displacements of the uterus, also endometritis. Other results may be pain on walking, on defecation, or during coitus; sterility or abortion; headaches, backache, neuralgic pains, neurasthenia, indigestion, constipation.

7. The *most common ovarian tumors* are: Cystic tumors; then sarcoma, carcinoma, endothelioma, myoma, fibroma; the three latter are somewhat rare.

The cystic tumors, sarcoma, and carcinoma may attain to great size.

8. The *indications for ovariotomy* are given by Treves as follows: Ovarian tumors and cysts; persistent hyperemia of the ovary; ovaritis; amenorrhea, attended with hystero-epilepsy; occlusion, or absence of uterus or vagina, with violent molimen; certain cases of uterine tumor; neuralgia of the ovary; some cases of mania, epilepsy, and hysteria.

9. CYSTITIS.—*Symptoms*: Frequent micturition; pain; bladder irritability and tenesmus; the urine may be alkaline and turbid, and may contain blood, pus, mucus, or bacteria; the patient may also experience chills and fever.

Treatment: Rest in bed; the imbibition of plenty of milk and water, and the avoidance of all highly seasoned food; laxatives; diuretics; sitz-bath; irrigation of the bladder with an antiseptic solution; hot fomentation and vaginal douches are often helpful; sometimes intravesical medication is necessary.

THERAPEUTICS.

1. Acids are classified as: (1) Mineral, and (2) Vegetable or as (1) Inorganic, and (2) Organic.

2. Scilla may be classed as an expectorant, an emetic, and as a diuretic.

The officinal preparations and doses are: Fluidextractum scillæ, ♏ij; tinctura scillæ, ♏xv; acetum scillæ, ♏xv; syrupus scillæ, ♏xxx; syrupus scillæ compositus, ♏xxx.

3. *Digitalis is contraindicated*: (1) When it produces precordial distress; (2) if it makes the pulse irregular; (3) in valvular lesions accompanied with compensatory hypertrophy, or when such hypertrophy is taking place; (4) in aortic lesions, generally; (5) in fatty heart; (6) in aneurysm and cerebral endarteritis.

Digitalis is incompatible with: Cinchona, lead acetate, iron sulphate, and the tincture of the chloride of iron.

4.

	DOSE FOR CHILD OF ONE YEAR.	DOSE FOR ADULT.
Acetanilid.....	Should not be given.	gr. iv.
Tincture of opium.....	♏ss: but the camphorated tincture had better be given. ♏v.	♏ viij.
Tincture of gelsemium	♏ss.	♏ viij.

5. *Officinal preparations and doses of Strophanthus*: Tinctura strophanthi, ♏vij; strophanthinum, gr. 1/200.

Strophanthus is used as a cardiac stimulant, in cardiac dyspnea, in several forms of cardiac disease, and nephritis, in pulmonary edema, hysteria, chlorosis, palpitation, and tumultuous heart action.

6. *The most generally used Anthelmintics* are: Aspidium: oleoresina aspidii, gr. xxx. Granatum: Pelletierinæ tannas, gr. xij. Pepo; ʒjss. Santonin; gr. j. Quassia; gr. xx. Thymol; gr. xij.

7. *The most important alkaloids of Opium* are: Morphine, codeine, narcotine, thebaine, narceine, papaverine.

Treatment of acute opium poisoning: "Wash out the stomach with a dilute solution of potassium permanganate, leaving about 500 c.c. in the stomach, and in maintaining the respiration. In the first or second stage the 'ambulatory treatment' should be adopted to prevent, if possible, the establishment of the third stage. If this stage develop, the main reliance is to be placed in maintaining the respiration by artificial methods, until the poison has been eliminated. Strong coffee, or caffein, by the mouth or rectum, are of benefit. The same cannot be said of atropin. The urine should be drawn by the catheter." (Witthaus' *Essentials of Chemistry*.)

8. *Antidotes* are agents given to counteract the effects of a poison. They may be divided into two classes:

Chemical antidotes act as such by uniting chemically with the poison, and thus converting it into a harmless or insoluble compound.

Physiological antidotes act as such by combating the physiological action of the poison.

9. *Antipyretics* are used to reduce the body temperature when it is abnormally high.

Antipyretics generally used are: Cold water, ice, aconite, quinine, acetanilid, antipyrin, acetphenetidin, digitalis.

10. A drug which when taken internally causes contraction of the pupil of the eye: morphine.

One which acts similarly when applied locally: eserine

OBSTETRICS.

1. The anatomic differences (not including the sexual organs), between the male and female figure are: In the male, the bones are stronger, heavier, with prominences and ridges more pronounced; the sternum is longer; the pelvis shows marked differences, notably in the subpubic angle, which is from 75° to 80° in the male and from 90° to 100° in the female; the thyroid foramen is oval in the male and triangular in the female. The female has more subcutaneous fat, hence the body is more rounded. There is less hair on the female body, notably on the face, chest, limbs, and abdomen; the pubic hair does not grow upward toward the umbilicus as in the male; the hair on the head is characteristically different. In the female the larynx and waist are smaller than in the male; while the hips are wider and the breasts larger.

3. A *diagnosis of occipito-posterior position may be based* on: Finding the sagittal suture in the oblique diameter of the pelvis, the posterior fontanelle in the posterior half of the pelvis, the anterior fontanelle is easily accessible; the fetal heart sounds are heard far back in the flank, between the ribs and the crest of the ilium; the fetal head may be felt above the pelvic brim, and the fetal small parts are felt through the anterior abdominal walls of the mother, while the fetal back is not felt.

5. The *most reliable signs of pregnancy before the fourth month*, are: Suppression of the menses, nausea, softened cervix and lower uterine segment, and enlarged breasts with darkened areola.

6. Conditions that justify the induction of premature labor: (1) Certain pelvic deformities; (2) placenta prævia; (3) pernicious anemia; (4) toxemia of pregnancy; (5) habitual death of a fetus toward the end of pregnancy; (6) hydatidiform mole; (7) habitually large fetal head.

The methods that may be employed, are: Partial dilatation of the cervix and the introduction within the cervix (and vagina) of a tamponade of sterile gauze; (2) dilatation of the cervix; (3) puncturing the membranes; (4) introduction of a soft rubber bougie into the uterus; (5) intrauterine injection of glycerin, water, or some other fluid.

8. *Puerperal eclampsia* is an acute morbid condition, occurring during pregnancy, labor, or the puerperal state, and is characterized by tonic and clonic convulsions, which affect first the voluntary and then the involuntary muscles; there is total loss of consciousness, which tends either to coma or to sleep, and the condition may terminate in recovery or death.

The line of *treatment* as laid down by Edgar is as follows: For *preventive treatment*: (1) The amount of nitrogenous food should be diminished to a minimum; (2) the production and absorption of poisonous materials in the intestines and body tissues should be limited and their elimination should be aided by improving the action of the bowels, the kidneys, the liver, the skin, and the lungs; (3) the source of the fetal metabolic products and the peripheral irritation in the uterus should, if necessary, be removed by evacuating that organ.

The *curative treatment* includes: (1) Controlling the convulsions (by chloroform, veratrum, or chloral); (2) elimination of the poison or poisons which are presumed to cause the convulsions; (3) emptying the uterus under deep anesthesia, by some method that is rapid and that will cause as little injury to the woman as possible.

9. *Version*, or turning, is a procedure by which some part of the fetus other than that originally presenting is brought to the superior strait of the pelvis.

The *varieties* are: (1) Cephalic, in which the head is brought down; (2) podalic, in which the (breech or) feet are brought down.

10. Ectopic pregnancy is a pregnancy in which the ovum is developed outside of the uterine cavity.

Its *dangers* are: Rupture of the gestation sac, hemorrhage, shock, pelvic hematocele, peritonitis, sepsis, and death.

Treatment consists in a laparotomy, and removal of the gestation sac as soon as the condition is recognized.

CHEMISTRY.

1. The *law of multiple proportions*: When two elements, *A* and *B*, unite with each other to form more than one compound, the various weights of *B* which combine with a fixed weight of *A*, are simple multiples of the smallest weight of *B* so combining.

2. The formula for ammonia is NH_3.

Ammonia water is a colorless liquid having the characteristic odor of ammonia. It imparts a blue color to litmus paper. If a glass rod moistened with hydrochloric acid is held over ammonia water, dense white fumes are evolved. Ammonia water when added to ordinary water makes a good cleansing agent.

3. Nitric acid acts very energetically on animal matter; it decomposes the same, and turns proteid substances yellow. Nitric acid is a colorless, fuming liquid, with a penetrating and irritating odor, and very sour taste: it is strongly acid in reaction; is a powerful oxidizing agent, and reacts readily with most metals to form nitrates: on exposure to the air and light it becomes yellow, and is decomposed into NO_2, H_2O, and O.

4. The acid used in preparing sulphite salts is sulphurous acid.

5. Three reliable tests for albumin in the urine:

"The urine must be perfectly clear. If not so, it is to be filtered, and if this does not render it transparent, it is to be treated with a few drops of magnesia mixture and again filtered."

I.—*The heat test*: "The reaction is first observed. If it be acid, the urine is simply heated to near the boiling point. If the urine be neutral or alkaline, it is rendered *faintly* acid by the addition of dilute acetic acid, and heated. If albumin be present, a coagulum is formed, varying in quantity from a faint cloudiness to entire solidification, according to the quantity of albumin present. The coagulum is not redissolved upon the addition of HNO_3."

II.—*Heller's modification of the nitric acid test*: "Place in a test tube a layer of HNO_3 about 2 centim. in thickness; then, with a pipette, carefully float upon the surface of this a layer of the urine in such a manner that the liquids do not mix. If albumin be present, a cloudy ring appears *at* the point of junction of the two layers, the borders of the cloud being sharply defined. A cloudy ring may be formed by the presence of an excess of urates, but in this case it is not *at*, but *above*, the point of junction of the layers, and its upper border is not sharply defined, but fades off gradually."

III.—*The trichloracetic acid test*: "It is more delicate than Heller's test. Add a crystal of trichloracetic acid to the suspected urine; the acid dissolves, forming a layer underneath the urine. A white band at the junction shows the presence of albumin." (Witthaus' *Essentials of Chemistry*.)

6. In *poisoning by match heads*, give an emetic such as copper sulphate or apomorphine hydrochloride; then old French oil of turpentine should be administered; avoid giving oils and fats; a weak solution of potassium permanganate has also been recommended.

7. Rat poison means poisoning by either phosphorus or arsenic. In the former case, the treatment is as just described in answer to question 6.

In poisoning by arsenic, the stomach should be washed out: an emetic such as copper sulphate or apomorphine hydrochloride should be given; and the antidote, freshly prepared solution of ferric hydroxide should be administered.

BULLETIN OF APPROACHING EXAMINATIONS.†

STATE.	NAME AND ADDRESS OF SECRETARY.	PLACE AND DATE OF NEXT EXAMINATION.		
Alabama*	W. H. Sanders, Montgomery	Montgomery	June	16
Arizona*	Ancil Martin, Phoenix	Phoenix	July	6
Arkansas*	F. T. Murphy, Brinkley	Little Rock	July	14
California*	Chas. L. Tisdale, 1879 Sutter Street, San Francisco	San Francisco	August	4
Colorado	S. D. Van Meter, 1723 Tremont Street, Denver	Denver	July	7
Connecticut*	Chas. A. Tuttle, New Haven	New Haven	July	14
Delaware	J. H. Wilson, Dover	Dover	June	16
Dist. of Col'bia	Geo. C. Ober, Washington	Washington	July	14
Florida*	J. D. Fernandez, Jacksonville	Jacksonville	Nov.	11
Georgia	E. R. Anthony, Griffin	Atlanta	Oct.	6
Idaho	W. F. Howard, Pocatello	Boise	October	6
Illinois	J. A. Egan, Springfield	Chicago	June	—
Indiana	W. T. Gott, 120 State House, Indianapolis	Indianapolis	Oct.	27
Iowa	Louis A. Thomas, Des Moines	Des Moines		
Kansas	D. P. Cook, Clay Center	Kansas City	June	9
Kentucky*	J. N. McCormack, Bowling Green	Louisville	July	7
Louisiana	F. A. LaRue, 211 Camp Street, New Orleans	New Orleans		
Maine	Wm. J. Maybury, Saco	Augusta	July	7
Maryland	J. McP. Scott, Hagerstown	Baltimore	June	9
Massachusetts*	E. B Harvey, State House, Boston	Boston	July	14
Michigan	B. D. Harison, 205 Whitney Building, Detroit	Ann Arbor	June	9
Minnesota	W. S. Fullerton, St. Paul	St. Paul	June	10
Mississippi	S. H. Mc'ean, Jackson	Jackson	Oct.	13
Missouri	J. A. B. Adcock, Warrensburg	St. Louis		
Montana*	Wm. C. Riddell, Helena	Helena	October	6
Nebraska	E. J. C. Sward, Oakland	Lincoln		
Nevada	S. L. Lee, Carson City	Carson City	Nov.	2
N. Hampshire*	Henry C. Morrison, State Library, Concord	Concord	July	15
New Jersey	J. W. Bennett, Long Branch	Trenton	June	16
New Mexico	J. A. Massie, Santa Fe	Santa Fe	July	13
New York	C.F. Wheelock, Univ. of State of New York, Albany	New York, Albany, Syracuse, Buffalo	June	23
N. Carolina*	G. T. Sikes, Grissom	Winston, Salem

THE WINNING FIGHT AGAINST CONSUMPTION.*

By JOHN B. HUBER, A.M., M.D.,

NEW YORK.

VISITING PHYSICIAN TO ST. JOSEPH'S HOSPITAL FOR CONSUMPTIVES.

It was peculiarly gratifying to me, a physician, to have been invited through the State Department of Health to speak to you, who are clergymen, upon the subject with which this exposition is concerned. I thought it a situation most fortunate that you should take the interest you are manifesting in the fight against a disease which has, up to our day, caused more human suffering and disaster than any other destructive factor in history; that your profession is joining that of medicine in this anti-tuberculosis propaganda. It seems to me that nothing could be more natural than such a union of forces. In primitive times, when human conditions were elemental, that man who was especially anxious for the welfare of the community combined in himself the offices of both priest and physician; while he sought to minister to the spiritual comfort of his fellows, he did also what he could to assure their physical well-being. And even in our day the church recognizes this instinctive union of humane forces, and finds that it can best extend its beneficent influence when it sends forth medical missionaries. Nor do we have to go beyond our own borders for inspiring examples of the co-working of the ministry and medicine for the amelioration of human suffering. You all know of the work of the Reverend Dr. Worcester who, as it happened, was a professor of psychology and of the history of philosophy before he became a clergyman. Being mindful, in a broad way, of the altruistic and humanitarian obligations which the Master has enjoined upon His disciples, Dr. Worcester enlisted the cooperation of physicians especially skilled in nervous diseases, to the end that by their united efforts those men and women who are suffering from functional nervous affections might become well body and soul. And Bishop Fallows, as you know, has set out upon the same work in Chicago.

Therefore, gentlemen, when you, as Christian ministers are taking a vital and an achieving interest in this much more important matter of tuberculosis, you are doing something most fitting and natural.. The good which can thus be got from a union of religion and science is incalculable. Indeed, gentlemen, I believe that religion and science have always been in unison; there has always been, and should always be a union of these beneficent agencies. They are one because they exist for but one purpose—the good of humankind. Whatever differences there have been have had, to my mind, nothing to do with essentials, but only with nomenclature; not concerning the heart of things, but only concerning words. And I have throughout conceived this paper, not in the spirit of a member of one profession addressing the members of another, but as one man speaking to his fellow-men, all of us having the inspiration of a single motive—to alleviate human suffering; all of us feeling the impulse of a single and a most potent faith in the accomplishment of our beneficent ends.

The Nature of Tuberculosis.—There is no phase of life which tuberculosis does not touch—nay, upon which it does not press with a most grievous, heavy hand. It has been claiming, between infancy and old age, every tenth life, and between adolescence and maturity every third or fourth life—in some communities every other life. Every other adult negro succumbs to it. Here lies the gist of the whole anti-tuberculosis propaganda. It is between the fifteenth and the forty-fifth years, between those years when young men and women are privileged to contemplate matrimony, when husbands should be strong to work for and maintain their families, when wives should be strong to rear their children, between the years when you and I should be fit for the world's work, that this dreadful disease has been destroying every third or fourth life. And much more is connoted by this death-rate. The consumptive is usually a pathetic sufferer during several years before his death; and during many months he has been incapacitated for remunerative work, so that his family have been in want because of his inability to provide for them; they have become exhausted in nursing him; they have, in their sympathetic devotion, only too frequently contracted the disease from him; their affection and their anguish in his behalf have been a tremendous strain. And many consumptives recover after months and years of grievous illness; so that the death-rate here given in no way suggests such suffering.

And shall we for the moment set aside considerations of sentiment, of pity; shall we look upon the matter from a purely material, Gradgrind viewpoint? Shall we compute what tuberculosis is costing us in cold, hard cash? An intensely practical spirit has come to be representative of our present day civilization; and of this we Americans are exceedingly vain. In the popular phrase, most things are now centered in the question "does it pay"; and whatever fails to come up to the piece of money standard is eschewed contemptuously. To understand adequately this tendency one has but to contemplate, for so long as he can endure to look upon it, the characterization of Mammon which Mr. Watts has painted. Such being the tendency of our civilization, it is nothing short of amazing, the economic losses which we permit tuberculosis to inflict upon us; amazing how the shrewdness, the business prescience of our people has in truth a

*Read before the Ministerial Association of Rochester, N. Y., March 30, 1908.

vision which reaches no farther than the essentially obtuse angle the apex of which is the end of its nose. Tuberculosis is a disease entirely preventable, and by means extraordinary for their simplicity and their comparatively little cost. Yet Dr. Pryor estimates that every year it brings to the people of this State a loss of $70,000,000; and this disease occasions the United States an annual loss of more than $300,000,000.

Society's "submerged strata," which cannot free themselves from the grip of pestilent environment —the darkness, wretchedness, and starvation upon which the saprophytic bacillus propagated its inconceivable billions, yield victims far in excess of all other infections put together. The poor, indeed, furnish much the larger part of the dreadful tuberculosis mortality; and this we are determined is a situation to be remedied. A generation ago it was said that the rich sometimes got well of consumption, but the poor never. And our propaganda is to-day manifesting that the poor shall recover equally with those who are prosperous.

It is, indeed, sometimes wondered why the well-to-do, being in seemingly wholesome circumstances, ever contract the disease; they are in fact no freer from the danger than were the gallants and gentle ladies in Poe's dreadful tale, who thought by isolating themselves to escape the Black Death. For the beautiful laces and garments of the rich, and the pretty things worn by their little children, and oftentimes got at remarkably low prices (and what manner of fool is he who will not buy a thing as cheaply as he can), are like as not worked at, and bent over, and coughed upon, from dawn until midnight, by sweatshop consumptives. So, much oftener than we imagine, does the poverty of Lazarus make itself felt in the house of Dives. Thus is demonstrated the fact, as in Poe's gruesome story, that all parts of the social fabric are inseparably interwoven, that no one part of our people can safely or successfully hold itself aloof from the rest; when any one part is afflicted, all must suffer in greater or less measure.

There is scarcely a trade, or occupation, or business or calling which does not, in varying degree, yield to tuberculosis its quota of valuable lives. And the factory has, up to recent years, been even more conducive to consumption than the home; the tuberculous workman has, in many communities, been infecting his fellow-workmen more than he has the members of his own family.

In literature and the arts how many precious lives have succumbed to this veritable captain of the men of death, to use John Bunyan's vigorous characterization. Consumption has ever been "death's direct door to most hard students, divines, physicians, philosophers, deep lovers, zealots in religion." Who can estimate the loss in beauty, poesy, in intellectual treasures, and in all the sweetnesses and refinements of life which this disease has inflicted upon us? How many an inspired genius, even before his powers have matured, has suffered its most untimely visitation?

In another place I have written: "It is with a very real sense of melancholy that one contemplates the long death roll of those of the world's great men and women who have succumbed untimely to the tubercle bacillus, which is and has been, through countless generations, by far the most potent of all death-dealing agencies. Had it not been for this detestable parasite Bastien Le Page might have given us another 'Joan of Arc' to feast our eyes upon; Rachel might for many years have continued to permeate the spirits of her audiences with the divine fire that was in her. Our navy did well enough in the 1812 war, as all the world knows; but what a rip-roaring time there would have been if John Paul Jones had lived to take a hand in it. We might have been reading some more of Stephen Crane's splendid war stories; we might have had some more of Robert Louis Stevenson's delicious lace work; Schiller might have given us another 'Song of the Bells'; we might have taken another 'Sentimental Journey' with Laurence Sterne; Henry Cuyler Bunner might have continued to delight us and to touch our hearts; John Keats might have given us another 'Endymion.' Had the tubercle bacillus permitted, Nevin might have vouchsafed us another 'Rosary'; von Weber another 'Euryanthe Ouverture'; Chopin might have dreamed another 'first Polonaise,' and the tender flute notes of Sidney Lanier might even now be heard. Maria Constantinova Bashkirtseff, Zavier Bichat, John Godman, Rene Theophile Hyacinthe Laënnac, Henry Purcell, John Sterling, Henry Timrod, Artemas Ward, Henry Kirke White, Henry David Thoreau, Baruch Spinoza, Paul Lawrence Dunbar—such names as these are but a moiety among those of the world's nobility whose precious lives were cut off in their prime by the Great White Plague."

The proverb goes "Trokner Husten—Todter Trompeter"; nor has the sword ever been as voracious of human life as has been the tubercle bacillus. And such scourges as cholera, the bubonic plague and smallpox, although they have been more gruesomely picturesque in their ravages, have never been in the running with consumption. Richat, for example, estimates the death roll of all the wars of the nineteenth century at fourteen million lives, and that of consumption in the same period and countries at thirty millions. That terrible fourteenth century epidemic of the bubonic plague, known as the Black Death, devastated three continents. During the several years of its continuance it is said to have destroyed—and the estimate is pronounced exaggerated—one-fourth of the populations it visited. But tuberculosis has been approximating that number of victims month in and month out, year after year, and so far as we can judge, throughout the history of the race.

Thus then does this disease affect every relation in life, every aspect of civilization—the infant subsisting upon impure milk, the child studying in unhygienic schools; the adolescent contending with the conditions peculiar to those years; the youth and the maiden; the mother, with whom lies the future of the race; the man who feels his natural responsibilities and obligations. Tuberculosis is pervasively concerned with our habits and customs, with our housing conditions, the sanitation of our cities, with innumerable details of existence. It has to do fundamentally with human destiny, with human heredity, its preservation, its course in the present life, its generations to come. The tubercle bacillus may well be looked upon as an index by inversion of the real progress of the race. By it the claim of civilization to dominate human life may fairly be judged. Tuberculosis will decrease with the essential advance in civilization; and this disease will as surely increase as civilization retrogrades.

The Causes of Tuberculosis.—It would perhaps be well to set forth here some elementary facts.

We speak of tuberculosis as a communicable disease, and we prefer this term to "contagion," which suggests a virulence not necessarily characteristic of tuberculosis. Diphtheria and scarlet fever are contagious diseases. If a passenger were sitting in a

street car next such a sufferer, it is not unlikely he would "take" the contagion from that mere contact. But consumption would not result so easily as that; one might, indeed, live his whole life with a consumptive and be able to resist the disease, by following the simple precautions which medical science has formulated. We speak generally of all diseases that are either communicable or contagious as infectious; they are all "germ" diseases. The existence of tuberculosis depends upon two main causes: the germ, which is the specific, the essential cause; and the predisposition.

The specific cause of tuberculosis is the bacillus of Koch, which that illustrious physician discovered in 1882. We call this germ a bacillus because it is rod shaped (*bacillus*, a rod); it is in reality a vegetable parasite which has been preying upon mankind, so far as we can judge, since the beginning of the race. Why, then, was it not discovered until within recent years? Because, in the first place, geniuses of Koch's caliber are very rare indeed; and again because we have not, until our day perfected a microscope by which we could detect an object so infinitely small. For this Koch bacillus is about one-ten thousandth of an inch in length; its breadth is one-fifth of its length, and the advanced consumptive coughs up several thousand millions—several billions of these germs in the twenty-four hours.

How does this germ find its way into the human body? First, by inhalation, by breathing in the airborne minute droplets of sputum which the careless consumptive emits; or by breathing in the dust which is impregnated with the consumptive's dried sputum. This is mainly the mode of invasion by the bacillus. Secondly, and perhaps nearly as frequently, the bacillus is taken into the body with impure food, especially with the milk and meat of tuberculous cattle; or the bacillus-laden excreta from the nose and the upper air passages are swallowed, particularly by little children, thus bringing about an ingestion tuberculosis.

When the bacillus finds an implantation in any vulnerable part of the body an inflammation is excited, resulting in the formation of a tubercle (*tuber*, a root or bulb); and thus we speak of tuberculosis, which is for all practical purposes the equivalent of the term consumption, or of the Greek "phthisis," a wasting away. Tuberculosis may exist in any part of the body. We are most familiar with it in the lungs—in the pulmonary form: but any other organ or tissue, the liver, the kidney, the spleen, the intestines, may be involved. Little children, especially, suffer from bone and joint tuberculosis; Pott's disease of the spine, hip disease, the white swellings, the cold abscesses of the elbow, wrist, knee and ankle joints are tuberculous manifestations.

Now, why is it, since the tubercle bacillus is propagated in such uncountable numbers, since it is ubiquitous—why is it that anyone ever escapes the disease? Because the bodies of most of us are sufficiently strong to withstand the germ; because we have within us such protective factors as phagocytosis and the normal opsonic index which destroy and assimilate the invading bacilli. But those who succumb have not these factors in sufficient strength to resist the invasion; they have become predisposed, by reason of poverty, starvation, or one or more of innumerable enervating and depressing agencies, so that their poor bodies have become incapable of resistance. How to eliminate the specific cause is the special business of the physician. And two main and very simple elementary principles have been evolved: to destroy the spittle of the consumptive before it can contaminate his fellows; and to require that food shall be innocuous regarding the tubercle bacillus before it is ingested. How to eliminate the predisposing causes of consumption is the special business of all other sorts and conditions of men and women.

The predispositions to tuberculosis may well be considered as hereditary, as environmental and as resulting from the infirmities of the will. These three factors, heredity, environment and will—these three fates, as it were—determine the destiny of the individual in this life.

It is a commonplace of experience that this triad of agencies are almost never isolated in their influence; they are essentially complemental and interrelated. A bad heredity may be most happily modified by a good environment; and a will, no matter how strong, may have to bend beneath the stress of a hard and uncongenial environment from which it cannot free itself. These facts of life confront our two callings every hour in the day. As I observed in the beginning, our nomenclature may differ. The same thing is meant when you speak of the sins of the father which are visited upon the children, and when the scientist speaks of hered[illegible]. We may here recall the whimsical Hibernic[illegible] Oliver Wendell Holmes that "A man ought to be careful in the selection of his ancest[illegible] often unfortunate that such is no one's privilege. The lives of most are begun healthy enough; but many are born with a most grievous handicap. Yet it is one of the most gratifying truths which the medicine of the present day can set forth that tuberculosis is itself almost never transmitted by the parent. I have noted that the essential cause, [illegible] which the existence of the disease depends, is the bacillus; but this is very rarely transmitted. [illegible] is oftentimes transmitted, however, by these sickly parents, is a predisposition to the [illegible] vitiated or vulnerable condition of the tissues, upon which the germ may [illegible] and propagate itself. They [illegible] sumption, but a tendency to [illegible] sumptive father may have a [illegible] This child may within several [illegible] sumptive. But not by her [illegible] intimate contact with the [illegible] or ignorant father has [illegible] germs which the careless [illegible] were impossible even [illegible] may bring about [illegible] mal physical life [illegible] relations to [illegible] of such [illegible] disaster [illegible] stone [illegible] the [illegible]

When we come to [illegible] cattered about the home. [illegible] nvironment we find that it [illegible] n to enumerate the factors which [illegible] a tendency to consumption. Normal [illegible] e is the right adjustment of [illegible] ernal [illegible] external relations; and any disturbance [illegible] justment leads sooner or later to physical [illegible] In those trades where minute particles of [illegible] or metal dust or cloth fiber must be inhaled [illegible] consumption mortality is very great—more than [illegible] per cent. among stone workers. Mechanical violence, blows, and wounds, oftentimes, by vitiating the tissues, furnish a focus of tubercular infection; a lowered resistance is brought about by such previous illness as acute fevers, "colds," grippe, pneumonia, and pleurisy.

It is, however, when we come to such vicious conditions as are attendant upon modern civilization that we find environmental influences of the deadliest sort. There is overcrowding, which necessitates that people must constantly be rebreathing their own poisonous exhalations, mingled with those of their fellows with whom they live; the dark and unventilated bedrooms in which hundreds of thousands sleep under circumstances so unhealthful that consumption has not without reason been termed

the bedroom disease; the dreadful poverty which millions have to endure in this country, which is probably the most prosperous and the richest in natural resources in all human history—poverty, with its connotations of sunlessness, starvation, and physical exhaustion; the lack of warmth, clothing, and shelter; the disease-breeding occupations which men must take up if they would keep their nostrils above the current in the dreadful struggle which is attendant upon what we like to term human progress—such are environmental conditions that have been bringing about the appalling death-rate that has been stated.

When we come to the part which a man's will plays with regard to tuberculosis one must consider his unhealthful habits, his improvidence, the unwholesome customs to which he adheres, his sexual aberrations, his dietetic excesses, his drug addictions, his misuse of tobacco, and among his vices, especially alcoholism. It is the last of these factors I would here consider briefly. The French say truly enough that alcoholism lays the foundation of consumption; again, that consumption is contracted across the bar. At any rate these retrogressive, sinister and destructive agencies are almost always concomitant. My own, and I think the general experience in hospitals and institutions for the poor, attest this. Yet here, I submit, the greatest charity should follow upon a consideration of elemental facts. Here we see illustrated in a way to engage our sympathies rather than our resentments, how oftentimes the will, how strong soever it would be, gives way beneath the appalling stress of circumstances. I submit with deference, despite magnificent examples to the contrary, that in the case of many human beings, normal physical conditions are demential to the maintenance not only of will but of that laty as well. It would seem strange to the uninterviewed, for instance, how many poor men, who safe too easily assumed to be depraved and vicious, drink whiskey of the wood alcohol or fusil oil verily before breakfast—before going to work. In one recorded case a quart of rotten whiskey was not infrequently taken before breakfast. Men essentially bad, men desirous of getting drunk, do not imbibe in this way; they reserve the evening for their debauches. The truth is that many wretched, unhappy men, having no choice between suicide and the will to live and determining upon the latter, as most heroic souls must, know no other means (however mistaken they may be) by which they can bring their subnormal organisms to the point sufficient for the doing of the day's work. They have in their bodies, which are oftentimes tuberculous to begin with, no factors of safety, no reserve strength with which to keep up the bitter and heartbreaking struggle for existence.

Another truth which experience has evolved is that oftentimes, in slum populations, the wives of these poor men do not know how to prepare for them a drinkable cup of coffee, or how properly to cook a piece of steak. It is easily demonstrable, indeed, that bad cooking has driven many a man to alcoholism.

When we, either as physicians or as ministers, are consulted by those who desire to marry, and who have the wisdom to seek our advice regarding that serious step, we should throw all the weight of our influence not only against the marriage of consumptives, but also against the union of those who are in any way predisposed to the disease. Under such circumstances the union should be delayed until both man and woman have fully recovered; oftentimes, when recovery has thus taken place, such a marriage under certain circumstances may be approved. The more love dominates such an engagement, the greater will be the willingness to wait. But with regard to the evident consumptive, we should press home the truth of Flick's dictum that "many a young man has sacrificed his chances of recovery on the altar of Hymen"; and the observation of another wise physician that when consumption is hanging about a young woman the distance between marriage and the grave is usually short with her.

A word regarding rural districts. We think oftentimes of consumption as being a city-bred disease. But, as you probably know, it is by no means rare in the country, and it seems strange, that the disease should exist when there is abundant pure air, so much benignant sunshine, such healthfulness generally. But I think it will be found that in many rural communities a number of abnormal factors exist. Sometimes it is the execrable, innutritious diet, to which meats (other than bacon) are comparative strangers—canned fruits and vegetables and condensed milk being largely consumed, while the fresh food-stuffs, including eggs, cream, and milk, are sent to cities. Then there is that innocent imbibition of cider, stomach bitters, and other irreproachably labeled fluids, containing anywhere up to 44 per cent. alcohol. Then there is in some parts, the effect of intermarriage among families which have through several generations been living within a radius of a few miles. Then there is the disregard of a natural function because of disinclination to venture to outhouses in the intense cold of the winter months. And there is, of course, the infection of homes which is possible in all living conditions.

Finally, before concluding my address, I would beg your help in the fight against a disease almost worse than consumption, and that is phthisiophobia, the fear of consumption. Fear in itself is a potent predisposing cause with regard to any disease; but when this unworthy emotion excites so many people to shun the consumptive, to fight with frantic and most selfish cruelty against the establishment of humane institutions for his relief, it appears to me that we should on every occasion most earnestly reprehend such behavior, so foreign as it is to the merciful spirit of Christianity. There is in fact, no danger from occasional contact with the consumptive under any circumstances; nor, indeed, at any time if the simple precautions which science has formulated are observed and practised. As I have stated, only the predisposed contract the disease; and the invasion of the bacillus must be frequent, intimate, and prolonged before an implantation is likely.

The Propaganda.—Thus, gentlemen, it is evident that tuberculosis is not merely a doctor's concern. Besides its medical aspect it presents many others—social, moral, political, and economic—than which there can be none more important in human affairs. The tuberculosis situation is the ultimate and personal business of every member of the community. Consider first the individual: how essential it is that the breadwinner's health shall not be endangered; how the mother should be made aware of the possible infection of her home; how the school child, in sufficiently advanced grades, should be instructed in the principles of sanitation and prophylaxis, so that hygienic and wholesome living will become a habit and an instinct. Indeed, I submit, that in the individual, the unit of our civilization, lies the most vital consideration of all. I know, as a physician, that the health of the human body depends

absolutely upon the stamina and the virility of its component cells; in like manner, no communal health can be hoped for otherwise than in the integrity of the individual being. Then we should influence our fellows as members of the community, as men and women represented in societies, leagues, labor unions, business associations, beneficent orders, church organizations.

Most potent of all beneficent influences is the education regarding the manifold phases of the tuberculosis propaganda. Physicians have been and are giving lectures to the laity in this regard. Circulars, pamphlets, and all kinds of literature have been disseminated. Exhibitions are imparting information in the most impressive and attractive way. The press has been most generous in the space it has given to the articles, reports and "stories" which have been prepared. Now, finally and most happily, we are to indulge the confident hope that the pulpit will reinforce this campaign of education with its all-powerful presentments.

No man or woman need be puzzled what part to take in this warfare against the Great White Plague. After the hygiene of the home has been attended to, efforts can be made in crossroad, village, town, and municipality to hold up the hands of the public officers who are charged with the care of the communal health. And these public functions can always be supplemented by the efforts and the funds of bodies which are organized apart from the constituted authorities. The cleanliness of public vehicles, street cleaning, school inspections, the abolition of slums, the providing of parks and playgrounds for children, should be matters of vital interest to the citizen. Health departments should be upheld in their measures framed for notification and registration, and for the disinfection of houses in which consumptives have lived or died. Tenement house departments should receive the sincerest and most unswerving support. And those of us who have surplus wealth can not possibly make better investments than in the construction and maintaining of model tenements for the poor. "Philanthropy with 4 per cent." is a most wholesome and at the same time one of the sanest of sentiments. There should be dispensaries for poor consumptives, which at the same time relieve the sufferer and through him educate the community. There should be camps for consumptive patients. Farm and tent colonies should be instituted. The establishment of sanatoria should be contemplated, for in them the patient is treated under the best possible conditions; while in such an institution he is not infecting his family, his fellow-workmen, and his community; and when happily he recovers he returns to his familiars as a missionary preaching the principle of hygiene and of prevention which have been inculcated in him. Hospitals and homes for advanced consumptives should be instituted, for while in them the sick man may mercifully end his days in peace he does not under such circumstances (as he would when at home) disseminate the infection in the gravest and most prolific of all ways. Hospitals for tuberculous children should be maintained, so that they may be cured of their joint and gland tuberculosis; so that they may not die at adolescence but may rather live to be a blessing and a bulwark of the body politic.

When we enlarge our endeavors beyond the local sphere we hold up the hands of our Health Commissioner and of the State Department of Health. We become deeply interested in laws for the regulation of factories, for the abolition, or at least the mitigation of exhausting woman and child labor, for the insuring of pure food, milk and meats for our people. We agree with the Roman publicist who proclaimed many centuries ago *Salus populi suprema est lex*—the public health is the supreme law. Widening again our viewpoint, we contemplate and anticipate a Federal Bureau or Department of Health so that the efforts making throughout all parts of our country shall be coordinated and mutually helpful. We shall with the truest patriotism strive for the removal of hard, unfair and cruel economic conditions.

We shall recognize with Lecky that "the great work of sanitary reform has been the noblest legislative achievement of our age, and if measured by the suffering it has diminished, has probably done far more for the real happiness of mankind than all the many questions that make and unmake ministries."

What prospect of ultimate victory have we in this fight against consumption? A fight half won is already won; and thus much is to-day accomplished. In Prussia tuberculosis has decreased forty per cent. In New York City, despite the most untoward conditions imaginable, the consumption death-rate has been cut down fully one-half during the last two decades. We have just come upon the report of Dr. Bulstrode, one of Great Britain's medical inspectors. Several years ago this noble worker declared: "The object of preventive medicine is to curtail and, if possible, to prevent disease, to prolong existence, and to render life happier by means of improved physical conditions." To-day he invites us to consider what such sentiments have wrought. In the year 1838 tuberculosis destroyed in England and Wales nearly 60,000 lives; in 1906, although the population within these boundaries has vastly increased, this disease destroyed less than 40,000 lives. The tuberculosis mortality in these countries in 1906 was about equal to the decrease observed in the preceding three decades; wherefore Bulstrode expresses the belief that, should the decrease in the death-rate continue in the same ratio, consumption should disappear totally from England and Wales within the coming thirty or forty years. Why then shall we not entertain the confident hope that before our children have grown to adolescence consumption will at least be bereft of most of the terrors which till now have attended it. How shall this hope be realized? By reflecting upon the diverse factors upon which the prophylaxis against tuberculosis depends. There has in the first place been the work accomplished by the medical profession, either as individuals or in the public service. To-day medical science has been the pillar of fire to lighten the way; and success has been achieved because the artisan, the tradesman, the plumber, the laborer, the builder, the contractor, the political economist, the statesman, the humanitarian, the churchman have all realized how many and varied are the etiological factors tending to consumption, apart from the specific cause. And they have all joined the physician, working together for the introduction of sanitary science (that babe in the family of sciences) into every phase of our infinitely complex modern civilization.

I end, as I began, in felicitating you upon the part you are taking in this crusade; your interest warrants the opinion that the beginning of the end is at hand. I am reminded of a crew shipshipwrecked upon a shore unknown to them. They saw before them only precipitous and inhospitable cliffs. Beyond these cliffs they knew not what they had to expect, possibly dangers greater than they had thus far endured, possibly death at the hands

of savage natives. One of the most venturesome climbed up this rocky coast, and scanned the horizon from the top. Presently he shouted to the rest: "It's all right, we're safe. I see a church steeple." And I am sure it is propitious indeed for us all when the clergy take part against "the disease of the people," the kith and kin of the founder of the Christian religion, the poor whom He so greatly loved.

THE UNFINISHED BUSINESS OF GENERAL HOSPITALS.*

By S. S. GOLDWATER, M.D.,
NEW YORK.
SUPERINTENDENT, MT. SINAI HOSPITAL; PRESIDENT, THE AMERICAN HOSPITAL ASSOCIATION.

In one year 59,528 patients were admitted to twelve representative hospitals in Toronto, Providence, New York, Philadelphia and Baltimore. The reports of these hospitals show an average mortality of only 9 per cent.; they show, also, that 35 per cent. of the patients treated and discharged, recovered completely from the illnesses for which they were admitted, that 50 per cent. experienced relief or improvement under treatment, that 4 per cent. were so unfortunate as to receive no benefit from treatment, and that 2 per cent. were not treated at all. These figures are shown in the following table:

	Hospitals	Total Number of Patients Disch'ged.	Recovered Cured or Well	Improved or Relieved	Unimproved; Not Relieved	Died	Discharged Against Advice	Not Treated and Trans. to Other Hospitals
1	Toronto General.....1906	3,616	....	3,100*a*	248	268	...	...
2	Massachusetts General.....1906	5,055	1,068	3,005*b*	194	489	128	171
3	Boston City, Boston.....1906	8,693	1,591	5,578	428	1,012	...	84
4	Johns Hopkins, Baltimore.....1906	4,064*c*	....	3,321*a*	108	263	...	372
5	Rhode Island, Providence.....1907	4,719	2,202	1,729	232	498	...	58
6	Pennsylvania, Philadelphia.....1907	4,153	2,245	1,281	213	414	...	...
7	Univ. of Pennsylvania, Phila...1906	3,583	1,988	1,046	153	259	...	137
8	New York, N. Y.....1906	9,377*d*	1,924	6,836	108	427	...	82

		59,528	20,536	29,550	2,644	5,527	128	1,143

(*a*) Includes well and relieved or improved.
(*b*) 1,525 much relieved, 1,480 relieved.
(*c*) Does not include 203 patients reported "transferred to other *departments*."
(*d*) Includes 5,865 patients treated in emergency ward.

Upon the whole, these hospitals appear to be making substantial contributions to the health of the community, and there is reason for pride in their achievements. One who is identified with hospital administration in however humble a capacity, may be pardoned if he acknowledges a feeling of complacency upon contemplating a work so far-reaching in its beneficence, and so typical of the spirit of democracy. But admirable as the administration of the typical voluntary or nonmunicipal hospital may be, it is not without its defects. Surely it is no part of the intention of those who provide the support or direct the work of a hospital, that some of those who appeal to it for relief shall be welcomed and comforted, while others are turned away, perhaps unnecessarily, without relief or aid; nor can it be maintained that the customary separation of applicants into the two great groups of hospital cases and nonhospital cases, has anything to do with the innate merit or demerit of the individuals so classified. Moreover, the admission of a patient to a hospital does not always signify his cure or even his material relief, and if upon inquiry it shall appear that hospital work, to-day, is unduly circumscribed by limits which are wholly self-imposed, we must try to throw off such voluntary and harmful restrictions. With this idea in mind, I shall ask you to consider briefly the needs of certain patients whose relations with general hospitals have been, and commonly are to this day, ill-adjusted and insufficiently fruitful.

Let us begin, then, by recollecting that in the main our voluntary hospitals are sound and useful, and within certain limits, efficient, that they confer far-reaching benefits on an immense number of patients, upon the friends and families of patients, upon the medical profession and the public; and that they have a decided economic value for the state. The relative neglect of certain patients of whose needs we are about to speak, might well be pardoned in consideration of the comforts bestowed upon those who are favored by the hospital methods which prevail. The aim of hospital administration, however, is not merely to merit pardon, but rather to win unqualified approval by raising itself to the topmost pinnacle of efficiency; and this is my excuse for focusing attention upon administrative defects which are, or seem to be, remediable.

Can we obtain a clear idea of the efficiency of a hospital from its official reports? If we could, it would be a simple matter to compare the work of one hospital with that of another, to set forth the differences in method which are associated with and cause important differences in result, and then, by a leveling-up process, to establish uniformity upon the plane of the highest known achievement. But whether we consider the very lean statistical summaries which are to-day found in every hospital report, or whether, hoping to get closer to the facts, we compare the results of treatment in different institutions as shown by the tables of medical, surgical, gynecological and other cases treated, we shall find our reasoning obstructed and obscured by the fact that these summaries and tables are the results of the use of widely varying standards in testing the condition of patients at the time of their discharge.

The obstinate patient who is officially cured but does not know it, and who returns to the hospital to confound the too optimistic clinical historian, is

*Read before the Medical Society of Johns Hopkins Hospital, Baltimore, March 2, 1908.

no stranger to any hospital. In fact, a hospital's report of the "cure" of a patient cannot be accepted as a literal expression of fact, and where real interests are at stake, it is not so accepted. Has any one ever known an institutional report declaring a patient "cured," to be received by life insurance experts as a guaranty of the securely established or reestablished health of a would-be policy holder? Take two hospitals doing similar work in similar ways: one, according to its records, "cures twice as many patients as it "improves"; the second, "improves" or "relieves" twice or three times as many patients as it discharges "cured" or "well"; naturally, upon discovering these discrepancies, the student abandons such records as hopelessly misleading, or at least confusing.

It is no easier to determine the exact status of the "unimproved" patient. In the reports of some hospitals, he has a way of slipping over into columns adjacent to his own, so that if we wished to count his kind we might begin by noting the number of patients officially "unimproved," but we should be obliged afterward to sift the ranks of the officially "improved," the "not treated," the "discharged against advice," and the "not admitted." So in the course of this brief inquiry into the neglected opportunities and the unfinished business of hospitals, I propose that we avoid figures which confuse, and adhere closely to facts which are patent; and inasmuch as a hospital may err, first, in declining to undertake the treatment or aid of an applicant, and secondly, in failing to do its best for admitted patients, it will be in order to consider the opportunities and responsibilities of the admitting department before passing on to the work of the wards. I beg of you especially to remember that in what follows I shall have no particular hospital in mind, but will try to keep before me the routine work of any typical general hospital.

Many patients in need of hospital care are refused admission on account of what is termed "want of room," or because there is said to be "no vacant bed." Now the term "no vacant bed" as used in hospital administration does not mean, or does not necessarily mean, that there is actually no single vacant bed in any part of the hospital, but only that there is no bed available in the particular ward or department to which, in the ordinary course of events, the case in question would be assigned. Or, if we consider a group of hospitals rather than a single institution, "want of room" may signify merely that a patient, in ignorance of the general situation, has applied for admission to a hospital which is hard-pressed at the moment, while if he had been better advised, he would have applied to another hospital where vacant beds are plenty. Without considering the erection of additional hospitals, what can be done to improve the chances of the average applicant for admission to any hospital in any large city?

Within the individual hospital, what can be done? First of all, we can substitute elastic department boundaries for rigid ones; we can give to some man or body of men in daily touch with the activities of the whole hospital, and capable of administering its affairs impartially for the greatest good for the greatest number, authority to add beds to, or subtract beds from, the various departments or services, in accordance with fluctuating needs. Suppose that ten, fifteen, or twenty per cent. of the beds in one department are unused for a period of a week, a month, or a year, while every other department in the hospital is overflowingly full and under the necessity of rejecting applicants daily.—shall such a state of affairs be tolerated? Does not common sense point the way to the removal of such an anomaly?

Among a group of hospitals, what can be done? Under a perfectly centralized municipal hospital administration, it would be possible, through the intervention of a central application bureau, for a patient in need of a bed to find his way promptly to the very ward of the very hospital where he could be properly accommodated. In a city like New York, however, or in any large city having the common, yet curious, mixture of municipal, private and semi-public hospitals, each independently administered, an ideally prompt and proper distribution of cases is impossible. Private or nonmunicipal hospitals will not readily submit to a centralized government; and the advocacy of such government, upon theoretical grounds, would lead to no good. But hospitals might retain their independence of control and might nevertheless join hands for the general good. For instance, they could work together under a system of organized voluntary cooperation, similar in method and effect to the scheme which the Hospital Conference of the City of New York has proposed for the government of the ambulance service of that city. The suggested ambulance system provides that the city shall be divided into ambulance districts, and that hospitals which accept district assignments shall inform a central ambulance bureau each morning of the number of vacant beds available for each class of emergency cases. An ambulance sent out for a case will receive its instructions directly from the central office; it will take a patient to the district hospital if there is an available bed there; if not, the patient will be transported to the nearest hospital which is known to have a suitable vacancy.

While the voluntary movements of patients free to apply for admission to any one of a dozen hospitals, cannot be controlled in exactly the same way as can the distribution of ambulance patients picked up in a given district by the ambulance serving that district, it would require no extraordinary wisdom to devise a scheme for keeping each hospital informed as to the daily condition of every other hospital in the same borough or district; and by using this information the members of a voluntary union of hospitals would be enabled to do infinitely better work than is done to-day by the same hospitals working independently of one another.

In some instances the rejection of a patient for want of room is recorded by the hospital, and the sum total of rejections due to this cause is known and published at the end of the year. But the reasons for other refusals are not explicitly given, although well worthy of consideration.* The fact is that hospitals are not, as yet, willing to assume any obligation toward a rejected applicant, and their unwillingness does not, at first glance, seem unreasonable or unduly narrow,—for otherwise there would appear to be no logical limits to the demands upon their limited resources.

And yet the hospital can afford to break its shell and look about it in the world; indeed, its influence

*The Boston City Hospital is the single exception known to the present writer; its report recounts applicants not admitted during the year, according to the following classification: For want of accommodation, self-rejected or deferred, for want of information, referred to out-patient department, referred to department for contagious diseases, nonresidents or no claim, chronic or incurable, pulmonary tuberculosis, delirium tremens or alcohol, venereal, pregnancy, insane or mental, miscellaneous.

will not be wholly good, nor will it approximate ideal efficiency, unless it does so. If it is not asking too much to propose that the bitter cup of rejection be sweetened by a little kindness and consideration, I would say that it is the duty of the application bureau of a hospital to admit a patient when possible; to refer an applicant to another institution or agency when necessary; to take as much pains suitably to place a patient who can not be admitted, as to admit a patient to whom hospital accommodations can be given; and to reject an applicant only when he can not be either admitted to the hospital or referred successfully to other sources of aid.

And after all this has been done, there will remain the duty of recording with care and minuteness, and of reporting with proper emphasis and comment, *all* of the work done by the admitting bureau, whether obviously to the credit of the hospital or the reverse. Hospitals may profit in this matter by the example of the telephone companies, whose operators record every delayed response and "busy" call, and who thus are enabled to win stronger support by showing subscribers where and to what extent their telephone service is deficient. By recording and classifying its own "busy calls," the hospital will learn to know and to reckon with its wider needs, and will thus be prepared to explain these needs to those upon whom it relies for support. Let us glance briefly at the most conspicuous groups of not-admitted cases, upon the disposition of which a full report is desirable, and which merit a degree of consideration rarely accorded them.

The hospital oftentimes receives the first visits of patients who, though not very sick, and properly classifiable as dispensary patients, nevertheless believe themselves entitled to hospital care.* Such patients are advised to go to the dispensary, and doubtless a certain proportion of them welcome the news that their admission to the hospital is unnecessary; but the vast majority prefer the continuous care of the hospital, with its free lodging, board and medicine, to the intermittent care of the dispensary doctor, who is not prepared to pay the patient's rent, or to provide the food and delicacies which are necessary to the cure which the patient is seeking. Is it sufficient merely to tell these patients, who clamor for hospital admission, that the proper place for them is in the dispensary? In many instances the refusal to admit them to the hospital is at once interpreted by them as an evidence of indifference, perhaps even as an act of hostility. To avoid such misunderstandings, the admitting department of the hospital must be so organized as to insure leisurely and sympathetic inquiry into the needs of each applicant, instead of a somewhat hurried examination, with the routine verdict of guilty or not guilty of being a hospital case. Assuming that every patient who is referred to the dispensary really belongs there, we should endeavor to get such a grip on him as to make sure that he will not slip out of our care. In some cases the patient's actual enrollment in a dispensary class may be as important to him and to his family and acquaintances, as would be his admission to the hospital; this is notably true of venereal cases.

The venereal patient is not wanted in the typical American hospital. Although the prevailing sentiment excludes patients of this class from the general hospital, their proper care is at least as necessary to the individual and as important to society as is the proper care of cases of typhoid fever or of any other dangerous infectious disease. In bespeaking consideration for the venereal patient, I am aware that I am making not the first, but the thousandth individual appeal, and that all who have preceded me have spoken in vain. The helping hand of the hospital draws back, because the sufferer is not clean.

It is recorded that forty years ago the house physician of a certain New York hospital was asked to defend himself for turning away from the hospital during the night a young woman in labor, who shortly afterward was taken to a neighboring stable by passersby and there delivered. The house physician justified his conduct by asserting that the woman wore no marriage ring and therefore was not a proper hospital case; and the explanation was accepted as consistent with the policy of the hospital. We repudiate such brutal policies to-day; we are accustomed to say that the function of the hospital is to relieve and not to punish, but we do not consistently live up to these high-minded declarations; the common practice in America is still to ignore, in large part, the needs of patients suffering from venereal infections.

The discrimination of hospitals against patients suffering from what are still regarded as shameful diseases, is sometimes attributed by physicians to the prejudices of the laity who support our private charities. But the argument limps; the prejudice is not solely, or chiefly, the prejudice of laymen. How often have the medical staffs of hospitals presented to their lay coworkers a united front in advocacy of a broader policy? With what degree of earnestness or persistency have they officially as a body, denounced the inconsistency of denying to a woman urgent treatment for acute gonorrhea, while standing ready to accept her as a hospital case when a surgical complication has set in? Or ridiculed the equal inconsistency of refusing to admit a man suffering from primary or secondary syphilis (when his admission would save him and his family from untold suffering), while standing ready to make room for him in the tertiary stage of the disease, when his constitution has been shattered and his wife and children have been infected?

But, putting aside our regrets for venereal cases that ought to be cared for in the wards of the hospital, let us consider the venereal patients who could be treated in the dispensary, and who for the present must be treated there, if anywhere. Is the situation made clear to such patients? Are they received as if they were welcome, or are they made to feel that they are in the presence of unsympathetic judges, and not of friends eager to help? Every case of this class which, on account of the coolness encountered in the examining room of the hospital, fails to be safely delivered into the hands of the proper dispensary department, is an indictment against prevailing hospital methods.

Consider also, if you will, the plight of another group of applicants,—those whom the public hospitals, especially, reject on the ground of foreign domicile. The nonresident patient who comes to the city for care to which he is not legally or by custom entitled, who requires an operation or other treatment for which there is no urgent necessity, whose means are limited and whose knowledge of hospitals and hospital rules is slight, needs not only a medical opinion, but the most explicit instruction. The advice given him should be full and free, and calculated according to his position and needs.

*In 1906, 10,543 patients applied for admission to Mount Sinai Hospital; of this number, 1,912, or nearly 20 per cent., were referred to the dispensary. It is impossible to say how these figures compare with those of hospitals generally, for the reason that very few hospital reports make any mention of cases not admitted to the wards.

The neurasthenic patient is another who will have little to be thankful for if dismissed with a diagnosis which accentuates the gloom caused by his rejection, and with no aid beyond a nod in the direction of the dispensary. If he is to be referred to a dispensary at all, it must be to a dispensary which takes its work seriously, and which is prepared to inquire into the patient's social condition and its relation to his disease.

The senile patient is one whose home affairs especially demand inquiry, with a view to determining whether the patient should be encouraged to enter an institution or should be returned to his family. While remembering that in such cases the burden of duty is always upon the next of kin, we must nevertheless inquire whether those who are responsible can without undue hardship stand the strain we would put upon them. The same thought applies to cases of mental disease, and to the whole multitudinous class of incurables. The admitting department can be of incalculable benefit to the friends of such patients, if instilled with the desire, and granted the time, to give sound and appropriate advice.

Of incipient tuberculosis, whose victims hold so prominent a place among the applicants rejected by general hospitals, it seems almost superfluous to speak. Tuberculosis has its special agencies of relief, prepared to deal more or less efficiently with any phase of any case; to provide for the disinfection of the home, for the conversion of the tenement lodging into a fresh air camp, for the better feeding of the patient, for a change of occupation, for the patient's removal to more healthful surroundings. Since the general hospital no longer attempts the impossible task of curing cases of tuberculosis by admitting them to a general hospital ward, the examining physician should see to it that the tuberculous who apply to him for treatment or diagnosis are placed in the care of the special tuberculosis dispensary, the district nurse, the charity organization society, the society for the employment of the handicapped, the industrial removal office, the board of health, or whatever agency exists in the community for the promotion of the patient's welfare. And in these days of the great organized movement for the social control of tuberculosis, the hospital should carefully tabulate and report upon all the cases of this group which apply for admission or treatment.

The pregnant woman, diseased or not diseased, is a familiar figure in every hospital anteroom; she is excluded from most general hospitals; and she receives, oftentimes, as a reward for her application, the bare statement of her condition,—a service for which her gratitude cannot be great. If she is needy, means of aiding her are close at hand, in the form of the lying-in hospital or the society devoted to the care of her class. The problem is merely to guide her to the proper door; but easy as this is, it is apt to be omitted.

The duty of the hospital toward a case of contagious disease will obviously vary according to the nature of the disease, the immediate condition of the patient, the character of the hospital, and the special facilities available. Wherever there exists a vigorous board of health, it is expected that cases of contagious disease will be referred to and cared for by this board. But many towns in the United States are still without special hospitals for the care of contagious cases; and in no city in the country, not even in New York, whose department of health has been for years a tower of strength for the support of the public health, is there an adequate hospital organization for the care of cases which should be isolated. One reason is that the needs of the department of health are not known. The liberal public support which is required by the department would be more readily obtained if the reports of hospitals laid due emphasis upon such phases of hospital incapacity as are known or assumed to be significant from the standpoint of public health. The attitude of hospitals toward erysipelas is illustrative.

Hospitals refuse to admit erysipelas because of the tradition that erysipelas is an uncontrollable contagious disease. How many such cases are refused in the course of the year, or what becomes of them, nobody knows; at present erysipelas is lost in the general summary of unclassified cases "not admitted"; neither hospital managers, the public, nor the public health authority, is made aware of what is happening, nor is guided by intelligent reports to a practicable and suitable method of relief.

Companion to the known contagious case, in the problems of hospital administration, is the contagious suspect. When contagious disease is suspected but not proved, the hospital should be ready with facilities for the temporary isolation of the case during the period of doubt. That such cases are sent home to blossom into exanthemata in the dangerously congested precincts of a tenement home, is a matter which should arouse the deepest concern; the avoidance of the practice would follow speedily upon an exposure of the facts.

Enough has been said to show that the admitting department of a general hospital presents many neglected opportunities of usefulness. It would be well if we could console ourselves with the thought that we bestow upon the patient whom we admit to our wards, the utmost attainable benefits of the science and art of medicine. Unfortunately, many a patient who is happily started upon the road to relief, falls by the wayside because he does not adjust himself to our personal peculiarities, or because we do not endeavor to understand his. Why is it that so often we fail to inspire perfect trust in our patients? Often, no doubt, the mischief is due to the patient's ignorance or superstition, or to suspicion rooted in unhappy experiences with other doctors. Yet I think we must concede that by means of a greater show of personal interest in our patients, we can lessen the number of those who leave the hospital against advice, and who, by this unceremonious departure, swell the army of the "unimproved."

It is true that some patients will not be persuaded, however sincere the interest in their welfare, however patiently the argument is put, however clearly the alternative consequences are pictured. But we must not fail to invoke every possible resource in a cause so good. There are in every hospital a few men, the possessors of rare personal charm or magnetism,—men who are unusually successful in dealing with insubordinate patients. We should employ their charm, apply their eloquence, where it is most needed. We should permit no patient to go untreated who by any means at our command can be persuaded to do what his own best interests require. The insubordinate patient is his own enemy, —it is a mistake to look upon him as an enemy of the hospital.

Lack of personal adjustment, then, is one possible obstacle to the adequate relief of hospital patients; another, more certainly avoidable, is to be found in the administrative isolation and the psychological tendencies of the specialist. In the statistical report of the Johns Hopkins Hospital for 1906, it is

noted that in the course of the year, 203 patients were transferred from one department of the hospital to another, evidencing an uncommonly high degree of departmental coordination. If similar figures appeared in the reports of all, or of many other hospitals, there would be no reason for referring here to the danger of placing the specialist in a position of administrative independence, and of encouraging him to pursue his work without cooperation or control.

The mental tendency of the specialist is toward a contracted field of interest, and therefore his contribution to the patient's welfare, however valuable, may reasonably be assumed to be neither comprehensive nor final. The danger does not lie in subjecting the patient to specialized routine, with its implication of rare and accentuated skill, but in taking it for granted that a very busy regional surgeon, for example, will do for a patient in a hospital, all that is done in private practice by the family doctor and the surgical specialist combined. I need not draw upon my own experience, nor ask you to draw upon yours, for clinical illustrations with which to support this view. When reciprocal support becomes the rule among hospital workers in different clinical departments; when active, persistent, and liberal cooperation becomes the universal practice, the readmission of patients will be a less frequent necessity, and the volume of effective hospital work will be greatly increased.

But with all of our available resources and skill brought freely into play, we may still fail to achieve the cure of the patient. What a sorry array of invalids marches into the hospital and out again each year, laden going as well as coming with burdens we strive in vain to remove. Conspicuous among them are the patients suffering from malignant diseases, who come too late for even an attempt at surgical relief, and go away labeled "inoperable." Others, similarly afflicted, but regarded as having a fair chance of cure, come for operation; and formerly, after operating upon them, we dared to discharge them as "cured." Experience has taught us modesty, and we now dismiss these patients as "relieved" or "apparently well." Rheumatism, heart disease, and chronic nephritis claim our beds in greater and greater numbers; diabetes staggers us by its frequent repetition and its obstinate return; hemiplegia and a host of nervous disorders clamor for admission to hospitals that shun them as undesirable chronic diseases, or admit them for a brief period of respite only. The patients who are afflicted with a vicious diathesis virtually incurable, come to us a first time in hope, a second time in doubt, and a third time in despair; they leave us, if, indeed, they leave us at all, carrying their unfortunate diathesis with them;—we are content, feeling that we have done our best.

Have we really done our best for those whom nature chooses to expose, beyond the breastworks of our available knowledge, to the attacks of diseases which we are powerless, as yet, to oppose? Can we maintain that we have used all our resources or exhausted our efforts, if we have not made it plain to every one how large a part of the domain of medicine is still unexplored, and if we have failed to plead for the privilege of further exploration? To acquit ourselves of the charge of negligence to our trust, we must teach the world that the proportion of hospital failures, the hospital's unfinished business with a large group of pitiable sufferers, cannot be materially diminished, or at all events is not likely to be, until every hospital becomes a scientific workshop, equipped with every resource for productive research,—not merely laboratories, and laboratory workers, but a medical organization planned to attract and hold and develop the best clinical minds.

The grouping of similar cases for purposes of intensive study has not been so much as thought of in half the big hospitals in the land; and in many of the other half it has not been attempted because the conception of the scientific mission of the hospital has won no commanding place in the minds of those charged with administration. And so it comes about that patients whom we would gladly aid, if we could, are deprived of their just dues, while hospital trustees listen to the whispers of a nearsighted kindness which declares it a sin to use human beings as objects of study, never stopping to consider the ends to which this study would be directed.

I often think that the preeminence of Johns Hopkins among American hospitals, has been won with an ease that is not creditable to other institutions. In wet-blanketing the ardor of scientific enthusiasm, in shutting their doors in the face of the research worker and its medical student, hospitals have abandoned their claims to distinction and have stunted their own growth. Sentimentality has commanded them to lock up their priceless storehouses of knowledge, and medical science in America has been half starved in consequence.

The failure to cultivate scientific opportunity represents one of the gravest forms of administrative unwisdom which can be charged against American hospitals. It is due to other forms of administrative defect that many patients who leave the hospital ostensibly cured, soon knock for readmission. Analyze these cases and you will discover that some patients, such as those barely recovered from an acute exacerbation of chronic endocarditis, or operative cases just out of bed, leave the protecting wing of the hospital too soon; and others, among whom are the diabetics, the neurasthenics, and the rheumatics, resume upon quitting the wards, occupations, and habits fatal to the hope of permanent relief; that still others, convalescent from pneumonia or typhoid, or suffering from chronic bone diseases or from incipient pulmonary tuberculosis, are the victims of a return to homes where fresh air is a stranger, where suitable food is unknown, where any food is scarce. These are the patients whose recognized needs gave the first impulse to the movement for the establishment of convalescent homes, and then prompted the introduction of the social worker as a hospital auxiliary.

Now, the welfare worker and the convalescent home can do much to supplement the routine work of the ward. They can, and do, in many an instance, transform tottering convalescence into stable health. But the supplementary needs of hospital patients often require more than either the social nurse or the convalescent shelter is able to bestow. On a future occasion I shall endeavor to show that these needs are such as can only be met by establishing a full-fledged department of personal hygiene, equal in rank to any other department in the hospital. The function of this department would be to take up the task of reestablishing the efficiency of the discharged hospital patient where the clinical therapeutist, with his drugs and his bedside paraphernalia, lays down this task, unfinished.

There is, it would appear, much that the average general hospital leaves undone. So remote and complex are many of the causes that contribute to disease, that the hospital cannot now or ever, hope

to discover or deal with them all. We cannot ask that the hospital shall undertake to remedy the faults of the whole social system; that it shall make all men prosperous, and shall grant them, as a part of prosperity, a reasonable chance for the preservation of health. It is not too much, however, to ask those who are concerned with the management of hospitals to keep before them always the ideal of the efficient hospital,—an ideal which can only be approximated through a knowledge of the actual and the possible defects of hospital work, and through a constant effort to remove the one and to avoid the other. And in seeking this ideal we have to remember,

That while failure to cure some patients is inevitable, the chances of successful treatment can be improved by the encouragement of scientific work; that the hospitals which have been, and are doing, most for hospital patients and for humanity, are those which provide liberally for clinical and laboratory research and for the education of the medical student;

That, indispensable as may be the specialist's contribution to the welfare of the hospital patient, it is prudent not to regard this service as self-sufficient or final, but wise rather to esteem it as a link in the chain of cooperative clinical relief;

That the patient's confidence is worth having; that good hospital management presupposes the use of every available means of winning the patient's confidence; that the discharge of a large number of patients contrary to the advice of the attending or house staff, without treatment or relief, is not creditable to any hospital;

That it is the duty of the hospital to cooperate to the fullest extent with every relief agency capable of benefiting those who have been, who are, or who may be, its patients, and that the fulfillment of this duty implies the elaboration of the all-too-simple admitting department;

That it is a function of the admitting department to record and to publish all that it does for the patients, *and, with equal emphasis, all that it fails to do,* to the end that all who are interested may know how to proceed to fill existing gaps in the organization of hospitals;

That in any city, and in most hospitals, beds are often kept vacant and patients refused the treatment they seek, when the voluntary cooperation of hospitals, in the one case, and the occasional crossing of unnecessarily rigid departmental lines, in the other, would fill the beds and save the patients;

That by the recognition of these truths, the efficiency of American hospitals can be greatly enhanced.

Mt. Sinai Hospital.

RECURRENT VOMITING.*

By HERBERT SWIFT CARTER, M.D.,

NEW YORK.

VISITING PHYSICIAN, LINCOLN HOSPITAL, CHIEF OF MEDICAL CLINI THE PRESBYTERIAN HOSPITAL DISPENSARY.

It is not the purpose of this paper to present a series of cases of cyclic or recurrent vomiting, no matter how interesting these would be, nor to discuss at length the variety of symptoms which may be met with. All internists, including pediatrists, together with ophthalmologists and neurologists, meet these cases from time to time and are more or less familiar with the symptomatology. My object is, however, to take up and discuss, in a brief manner, the various theories of its etiology and the problems of faulty metabolism with which the condition is almost always associated, as well as some points in its treatment.

To characterize the condition briefly, it may be called a symptom complex, occurring for the most part in children from two to twelve years of age (although occasionally met with in adults perhaps) in which there may be a few days or hours of prodromal symptoms, such as lassitude, constipation, redness under the eyes, etc., and followed often without these symptoms or any error in diet, by vomiting, at first of food, later of watery fluid with some mucus, without reference to ingestion of food, although usually aggravated by attempts at feeding; this may come on quite suddenly without warning, and often the only exciting cause is a fright or shock of some kind.

The temperature is normal, subnormal, or only slightly elevated; the pulse often becomes quite weak; the child at first looks fairly normal, but rapidly shows signs of a severe illness out of all proportion to the main symptom of vomiting, as from a severe intoxication; the skin is pale, often sallow; there is rapid loss of flesh and strength, with absolute inability to retain food or water by mouth. This condition lasts from two to fourteen days, with a gradual return to the normal and subsidence of all symptoms; this return to the normal may also occur very rapidly. Although these little patients look and are severely ill, the condition is very seldom fatal, only a few such cases being reported; but the attacks are always alarming to the parents, and usually most disconcerting to the attending physician. They are apt to recur at intervals, varying from a few days to weeks or months, but are usually not at stated intervals, although they may come very regularly.

In later life these patients may be sufferers from migraine, which in the adult is supposed to be the analogue of the recurrent vomiting in children. A certain number of cases of this form of vomiting in adults have been reported, but as practically all the attacks are reported as accompanied by severe pain, they are more probably examples of tabetic crises of intermittent abdominal claudication or some such condition, and not a true recurrent vomiting.

We are now in a position to take up the consideration of the question from an etiological point of view, and to that end may discuss to advantage the various theories* advanced in explanation of this phenomenon, based more or less on the metabolism of the body as shown principally by urinary changes.

Theory of Edsall.[1] According to this the condition is due to a grave acid intoxication of a type met with in diabetes. He found one child suffering from a severe attack in whom the blood was feebly acid, which he considers due to an abnormal amount of acidosis with absorption into the blood, so reducing its alkalinity. He explains the acidosis as due either to faulty metabolism or primarily to digestive disorders exaggerated by a disturbance of metabolism.

The acidosis, here as elsewhere in disturbed metabolic conditions, is due principally to a vicious fat metabolism, the oxidization of which under ordinary conditions yields energy to the body, and by complete oxidization is broken up into water and carbon dioxide. The intervening products are beta-oxybutyric and diacetic acids, which, so long

*Read before the Hospital Graduates' Club, New York, October, 1907.

*In discussing some theories considerable assistance has been derived from Dickinson's work.

as metabolism is intact, are further oxidized into the end products and never appear in the urine. When, however, this process of oxidization is interfered with, these intermediary products are retained, circulate in, and are absorbed by the blood, and are gradually excreted as such in the urine. The complete burning up of these acids takes place only in the presence of an accompanying combustion of carbohydrates, and if these are absent from the diet, as often in diabetes, these acids are then excreted as before stated. This is also the explanation of their presence in starvation.

If, then, the acidosis appeared *only* late in the course of the attack, the explanation would be simple enough on the ground of starvation, but this is not a fact, as it is frequently found early, or even before the acute onset, so that at least in certain cases, as Howland and Richards point out, the presence of these acids must be accounted for by a loss of power in the cells to oxidize carbohydrates.

Edsall, too, thinks that autolytic processes are increased in this condition, just as Alonzo Taylor, in studying the acid intoxication following chloroform anesthesia, found that apparently the acidosis was secondary to the increased autolysis. Edsall thinks that a possible explanation of the occasional good effects as well as failures seen in the alkaline treatment of this disorder may be found in this fact, because Rowland and Hedin discovered that autolytic processes are favorably influenced by acids, but unfavorably affected by alkalies.

Comby[2] considers the attack a manifestation of an arthritic diathesis, because (1) cases occur so frequently in children of arthritic parents; (2) of a certain analogy between cyclic vomiting and migraine; (3) of the possibility of these attacks being converted later into migraine, as a certain number of children with cyclic vomiting when young have subsequently developed migrainous attacks.

Snow[3] thinks that the condition is a simple gastric neurosis accompanied by hyperacidity, and absorption of ptomains can precipitate an attack. No satisfactory clinical or experimental evidence is adduced to support this.

The theory of Griffith[4] differs from the last in that he considers it a neurosis of toxic origin.

Rochford and Whitney[5] trace it to an hereditary arthritic diathesis, which, besides producing uric acid, also produces poisonous leucomains related to the purin bodies, which are diffusable and gradually accumulate until an outburst. They call it a "lithemic gastric neurosis."

Mery[6] blames constipation and thinks most of the cases are due to that.

Richardière[7] attributes attacks to insufficient liver function, as signs of hepatic derangement are often seen, and he considers that the acetonemia and acetonuria, which are the most constant symptoms, must be looked on as an effect of this, that the liver is no longer able to destroy or prevent the formation of acetone in the system.

Hutinel,[8] quoted by Gilberti, elaborates this hepatic theory. He says that normally the toxins which are formed as a result of metabolism are eliminated, but if the liver is not capable of doing this, the poison gets into the circulation. The reaction varies with the individual, as all persons do not show identical reactions to the same stimulus, so it results sometimes in rise of temperature only, or urticaria, or various nervous phenomena, and sometimes in vomiting of a periodic or recurrent type.

Broca,[9] apparently, because in two cases the attacks ceased after removal of the appendix, puts the blame generally on an unrecognized appendicitis.

Comby, giving various statistics in thirty-four cases, found that in only two cases the appendix was implicated. There were twenty-four girls and ten boys, more than two to one. The favorite age was between two and ten years. Constipation was found in thirty cases. Most of the children were of a neuroarthritic diathesis, and among the more wealthy classes.

Rachford[10] describes the condition as a migrainous-gastric-neurosis, and found alloxur bases in the urine the same as found in migrainous attacks in adults.

Theory of Howland and Richards. "By far the most satisfactory experimental explanation of cyclic vomiting is offered by these authors, who attribute the attacks to an intoxication arising from products of proteid putrefaction in the intestine, under circumstances which have resulted previously in a lessened power of oxidization of the body cells, and sum up by saying that they believe at the outset of the attacks there is an interference with certain metabolic processes in which oxidation plays a part, and that as the attacks wear off the urinary signs of this interference wear off too. The indican so universally present in the urine of these cases means an increase, not only of indol, but of skatol and phenol, and is a result of synthetic product of oxidization of indol. This they show very well in their experiments in dogs, for indol injected into healthy dogs causes little or no harm. If, however, the oxygenating power of the cells is lowered, as can be done artificially by chloroform inhalation or giving a small dose of potassium cyanide, and then phenol or indol be injected, the toxic effects are marked, causing nausea, vomiting, blindness, stupor, or delirium, and if the amount injected is large enough, death occurs in from three to several days. In these experiments it was noted that in the normal dogs, after an injection of indol, the substance was entirely excreted in twenty-four hours in the form of indican, whereas in the animals previously poisoned by chloroform or potassium cyanide the amount of indican in the urine was greatly lessened, and its excretion was prolonged over a much longer period.

The autopsy in the fatal cases showed marked congestion of the entire gastric intestinal tract, especially of the duodenum, lower ileum, and colon, with extensive necrosis of mucosa and submucosa. The liver showed great degenerative changes.

The autopsy in one case of a child who had died in the fifth attack, showed a liver which was large and the seat of a fatty degeneration; the kidneys were also fatty, but there was no nephritis.[12] Usually the fatal cases are due to a complicating nephritis, although it seems likely that in this case the vomiting was more of renal origin.

The application of these findings, experimentally produced, to the condition of cyclic vomiting is that "in children fright or a shock of some sort reduces in an unknown way the power of oxidation and the organism thereby loses the power to detoxify substances absorbed from the intestine, which have been present there in excess; these circulate in the blood, and since they are not brought to the kidneys in proper form for excretion are retained, so causing the symptoms. Finally, the power to oxidize and detoxify these substances returns, and they are rapidly eliminated with quick improvement." They do not think the toxic qualities all confied to indol. Incidentally, they found also that in these poisoned dogs peristalsis was excessively

active, but that little fecal matter was found; this may very likely be the explanation of the reason that cathartics are so slow and ineffectual when given after the attack has begun.

Holt[13] has found a deficiency of uric acid in the attacks; and in one case the uric acid urea ratio was 1:83, which in a normal condition in the same patient was 1:42.

In summing up these various theories we may state them briefly thus: That the condition of cyclic vomiting may be due to (1) a pure neurosis; (2) a toxic neurosis; (3) an acidosis from a vicious metabolism principally in the digestion of fats, with or without autolysis; (4) a toxicosis from intestinal putrefaction of proteids when accompanied by a suboxidative power of the body cells; (5) a rheumatic diathesis.

That the cases may in some instances be due to one or another of these causes, or to a combination of one or more, seems likely, and further study is needed to enable us to classify them promptly clinically, which is, of course, the important thing for us as physicians.

Treatment.—Although there is no specific treatment for this condition, either for the attack itself or in the way of positive prophylaxis, much may be done for the patient's comfort, the severity of the attacks may often be mitigated, and their occurrence made less frequent.

From the standpoint of its being a pure neurosis, there is little to be said therapeutically, except, of course, we must improve the nervous stability of the children by all known means, such as exercise, baths, and general hygiene; from the psychical point of view nothing can be accomplished owing to the age of these little patients.

From the point of view that it is due to a real toxemia (as about most cases, if not all, there is little doubt in the minds of careful observers that it is so) we must first know the actual conditions present. Is it due to an acidosis? We must use alkalies. Is it due to a poisoning from the phenol group? We must purge them. If suboxidation is at the bottom of the trouble in association with the intestinal toxins, can we do anything to increase this, or must we wait many days to let nature do our work for us?

In this last connection it might be well to try the effect of thyroid extract on purely theoretical grounds, giving it by mouth if possible in small doses, or by hypodermic injection, or by rectum, as this substance increases metabolism by a direct increase of oxidizing power of the cells under ordinary conditions, and whether it would act under such abnormal metabolic circumstances can be determined only by trial; no reference to its use has been found in the literature on this subject.

One thing seems certain—that constipation holds a very fostering position in relation to these attacks, being present in thirty out of thirty-four cases already alluded to. It should be everlastingly combated in the children prone to such attacks, first, by all dietary means possible, under which may be mentioned the bran biscuit, regular habits, water drinking, abdominal massage, etc. In most cases it is a good plan to give these children calomel at regular intervals, every seven to ten days to insure a good cleaning out, if the attacks are frequent or severe; otherwise, rhubarb, magnesia, etc. As these children, with care and an increasing nervous stability, outgrow this tendency, there need be no fear of their becoming addicted to cathartics.

Then, too, those cases which are apparently due to acidosis or to uncertain cause, are often kept better by giving constantly or from time to time small doses of an alkali, bicarbonate of sodium being the one most easily given.

In the prophylaxis of future attacks, besides the occasional laxative the best results have been obtained by restricting in the diet the excess of proteid and carbohydrate foods, particularly the sugars, and making up their loss by an abundance of fats in the form of cream, fresh butter, fat meat, etc. If one must use salted butter, it should be worked over in fresh water to remove as great an amount of the fatty acids as possible.

For the attacks themselves we must do what we can, besides the initial cathartic, which may or may not be retained, and will work slowly and often unsatisfactorily at best. The indications are to supply fluids to the tissues in large amounts to dilute the poison, and food in small amounts, the latter by far the most difficult undertaking. In this connection it might be of service in certain of the cases to use high colonic irrigations of an alkali solution, or in extreme cases even to give it hypodermically or intravenously.

As the vomiting is probably eliminative, due to the excretion of the poison by way of the gastric mucous membrane, it will be seen that the usual antiemetic remedies will be useless. It is useful, however, to give fairly large draughts of either plain or alkaline water, with the idea that it will be promptly vomited, and so accomplish autolavage; or actually to wash out the stomach at intervals.

Valenti,[14] experimenting in dogs, found that after cocainizing a small area at the back of the throat at its junction with the upper end of the esophagus, he was able to give large doses of emetics which act centrally, *e.g.* apomorphine, with no resulting vomiting, and also locally acting emetics, which only had an effect several hours after the drugs were given, when in fact the effects of the cocaine had worn off. This may or may not prove valuable in these cases, for if successful, although in no way limiting the course of the disease, it would do much in the severe cases to save the patient's strength.

So far as rectal feeding goes, here as in other conditions it is most inadequate, for in spite of much that has been written in its favor, when actually put to the test, from the standpoint of metabolism, it fails; for by estimating the rectal intake of nitrogen and balancing it with what is passed in cleansing enemata plus urinary nitrogen, it is seen that there is a steady and unsatisfied loss of body proteid. This I put to a practical test in several cases of rectal feeding, and found the total daily loss of nitrogen ranged from 8 to 24 gms., accompanied by a steady loss of body weight. These results tallied to a large extent with those obtained by Edsall[9] and Miller.[15]

If, however, it is decided to use the rectum for alimentation as well as for supplying water to the system, it will be of service to use much smaller amounts of *fully* peptonized milk (two to three hours) alone than is usually done; this is by far the best substance, as shown by what Chittenden found, that nitrogenous equilibrium could be maintained upon, namely, 15 gm. nitrogen per kilo of body weight. This would mean that a child weighing 25 kilos would receive 3.75 gm. nitrogen in twenty-four hours, or about 750 c.c. of milk, roughly a pint and a half. This is allowing an average of .5 per cent. nitrogen in milk, a convenient number to remember. This would furnish approximately 542 large calories, the actual needs of such a child being about 600 large calories, quite near

enough. Water should always be freely supplied by rectum or colon, even by hypodermoclysis if necessary.

These attacks of recurrent vomiting are always distressing and occasionally fatal. The care of the child during the attacks, in the prevention of future ones, or at least in making them infrequent, may well tax the patience and ingenuity of the physician.

THE NEW SCHOOL HYGIENE.*

By GEO. W. VANDEGRIFT, M.A., M.D.,

NEW YORK.

ASSISTANT SURGEON NEW YORK EYE AND EAR INFIRMARY; MEMBER NEW YORK COMMITTEE ON PHYSICAL WELFARE OF SCHOOL CHILDREN.

It is not hard for many of us to recall the day, a few years in the past, when we sat with half a hundred others in a steam-heated, window-closed, gas-lighted room, squeaking with soapstone on a spit-greased slate; sitting, those of us who were short, with feet dangling above the floor, and those who were long, with knees bent against the desks in front. It is not difficult to remember how we peered from dark corners of the room, straining to read the writing that dazzled with a thousand reflections from the distant blackboard. We who were nearsighted remained in our rear benches, while the smart boys with their emmetropic eyes, heads of the class, occupied the front benches. Others of us who were mouth-breathers and failed in our lessons were kept back and called dunces, and at home had clothes pins fixed to our noses if we snored at night. We were a private, if not a public nuisance, and were tolerated more or less only because some day we would outgrow talking through our noses and breathing through our mouths. The lower classes had a recess of a few minutes in the forenoon, to be spent not romping in the sunshine, but going down narrow, stone stairways to a dark, foul-smelling toilet, and back again up four or five floors to the classroom once more, where the atmosphere had been bottled up carefully and preserved to be breathed again. The big fellows in the upper classes were able to withstand, of course, the many demands of nature, and needed no recreation or exercise until dismissal.

Even in those days we were taught a little hygiene, while we sat in a vitiated atmosphere. The evil effects of alcohol and tobacco were displayed before us on highly-colored charts, though we saw our fathers and our uncles, and even our teachers, hale and hearty, though drinking and smoking.

*Read at a public meeting held March 20, 1908, by the East Side Physicians' Association.

Slates have entered the limbo of desuetude. Blackboards, we pray, will follow. In most of the schools properly constructed desks and windows give comfort, fresh air, and light to pupils and teachers. Many of us have been fitted with glasses, by opticians probably, or have outgrown our enlarged tonsils and adenoids. The teachers have lost their fear of fresh air and sunshine. Reports of the Board of Education show a decrease in the percentage of truancy in the year 1907 over that of previous years. While this decrease is due largely to an increased efficiency of the truancy department, and a more thorough administration of the Compulsory Education law, I think it due also, to some extent, to more inviting and pleasant school surroundings. In many homes knowledge has entered, and the old fetiches—mufflers, chest-protectors, closed windows—are losing their pristine power. Recent-day physicians are responsible for this beneficent change both at home and at school. We no longer may be called bleeders and leeches, but apostles of fresh air and sunshine. And though this change from the old ideas of hygiene to the new has been most noticeable in the school, it had its beginning in the home, where the family physicians have been teaching for many years the dangers of darkness and bad air. In the schools the changes have been most marked because there the movement for the new hygiene has been organized. The old teaching of hygiene, that dealt with the evils of alcohol and tobacco, and neglected the evils of unsanitary surroundings, has been giving way rapidly before the new teaching that deals with the correct habits of health and with the relation of health to happiness and efficiency. We are learning that social and physical defects are more threatening to the welfare of children than alcohol and tobacco. Unsanitary homes and schools, dirty streets, and infected milk, breed defective bodies that crave the excessive use of these poisons.

A hue and cry recently has arisen over the physical defects of school children. They are looked upon by many as something entirely new, something that has appeared, Minerva-like, portents of the future degeneration of the American race. Though 12,000,000 school children of the United States have more or less serious physical defects, there is no cause for panic or pessimism. There are no reasons to make us think that the percentage of children suffering from physical defects is higher now than ever before, only that the unsanitary conditions and ignorance prevailing amid the crowded environment of a great city to-day aggravate their seriousness. To quote from the recent report of the New York Committee on the Physical Welfare of School Children, "the only new thing about the physical defects of school children is not their existence, but our recent awakening to their existence, their prevalence, their seriousness if neglected, and their cost to individual children, to school progress, to industry, and to social welfare."

The movement of human endeavor is like the pendulum of a clock. It is trite to say we rush to extremes, but it is an axiom that we must bear constantly in mind in this struggle for new hygiene. We have passed the point of utter neglect; we are approaching the up-curve of the movement of the pendulum, and there is a tendency to-day to attribute to physical defects all those weaknesses of human nature that prevent us from reaching the ideal. Much backwardness in study, truancy, incompetence, crime, no doubt are due to physical de-

fects that prevent proper physical and mental growth; but, if there never were such things as physical defects, these human weaknesses still would exist. We must bear this in mind or our broth will be spoiled by too much handling. We must not expect to create ideal conditions by eradicating defects, but we must expect to lift to a higher and better physical and mental life many thousands of human beings, who would otherwise remain a barrier to the progress of civilization.

Briefly, then, the problem is this: At various times the Department of Health has declared that about one-third of the public school population is suffering from some one or more physical defects, that inhibit not only physical but mental growth. How can we correct most quickly and cheaply these defects, and, at the same time, prevent or at least curtail their prevalence in the future?

To attain this result we must learn in the beginning what are the causes of physical defects among children, and what conditions at school and out of school tend to aggravate them. At the start we must remember that many physical defects are congenital, and that others are aggravations of normal conditions. We must expect, therefore, to find them amid all classes of life, from the very poor to the very rich, among the country as well as among the city dwellers. We are born myopic, hypermetropic, and astigmatic; unsanitary surroundings aggravate these conditions, do not manufacture them. Adenoids and tonsils are normal tissues, necessary to the functions of the body. Follicles are normal in the conjuntiva. Only when unduly hypertrophied do these tissues become a menace to the health of the child. Other defects there are also, which we call acquired, such as enlarged glands, cardiac and pulmonary diseases, bone diseases, malnutrition, and, above all, defective teeth, which are caused directly by unhygienic school, street, and home surroundings.

The conditions that tend to cause or to aggravate physical defects fall naturally into two groups—unhygienic conditions at school, and unhygienic conditions outside of school, particularly at home. To prevent, as well as to cure physical defects, we must study these errors of school and home environment and correct them.

I wish to bring before you a few of the many practical facts obtained by the Committee on the Physical Welfare of School Children, in its study of the home conditions of 1,400 defective school children of the City of New York. The cases have been taken from schools both old and new; schools representing not only poverty-stricken and crowded districts, but also those well-to-do and spacious. Surprising as it appears, low incomes do not monopolize physical defects. Only 8.4 per cent. of the cases reported belong in families having an income less than $10 per week; 59 per cent. have more than $15; 43 per cent. have over $20; and 15 per cent. over $30 per week. Of the 1,400 cases only 145 are reported for malnutrition, in the face of the crusade for free meals at school. Though 50 per cent. go without milk, cereal, meat, or eggs for breakfast, only 2.8 per cent. report no eggs or meat during the day; and only 0.7 per cent. claim to have nothing for breakfast.

The housing conditions, however, especially among those of low incomes, were found to be highly unsanitary, so much so that we would expect to find amid them a larger number, and more serious defects than reported. Defects cannot be corrected by nourishment alone, nor will exercise in the open air outside of school and home counteract the results of bad ventilation and bad light within school buildings and homes. Plenty of food will not prevent bad teeth and bad air from causing adenoids, enlarged tonsils, indigestion, and malnutrition.

The number of sleeping hours has been found adequate, but more evils will result from a vitiated atmosphere in sleeping rooms than from loss of sleep. Diseases of early childhood, while preparing the soil for physical defects, have been no more common among the cases studied than among children in general. Finally, two further and most significant facts stand forth: 1. Children receive inadequate medical care, only 60 per cent. of all examined using a private physician, and only 30 per cent. a dispensary. 2. Children receive inadequate dental care, only 27 per cent. of those examined employing at any time a dentist, though of the 1,400 cases 74.9 per cent. had defective teeth, a terrible menace to the health of the growing child.

These unhygienic conditions at home, bad as they are, are being remedied slowly. Many a crowded tenement can be made cheerful with light and air. The burden (it is a light one, surely) of the work rests upon the shoulders of the practising physicians. They touch more closely the lives of the people than do any others; and the Boards of Health and Education cannot eradicate physical defects until conditions at home are on a more sanitary level than they are to-day.

Conditions at school, that cause or aggravate physical defects, are being remedied, new schools being well lighted and well ventilated. It is a pity that each school cannot have an adjoining park as a playground, but at least the dark, foul-smelling, cellar playground of former days is disappearing. Much still can be done, however, not only in building construction, but also in correcting mistakes in school curriculum, number and length of school days, home study, and text books.

The sessions are too long for the growing children. No matter how good the ventilation, a room filled with many lungs soon has a vitiated atmosphere. Smaller classes, shorter sessions, more physical exercise and recreation during school hours, better books and less home study, a curriculum adapted to physiological, not chronological, age, will diminish the need of glasses, tonsilotomies and adenectomies.

Two measures for the eradication of physical defects we have, preventive and curative, that knowledge and experience gradually will perfect. To prevent physical defects we must eliminate all those unhygienic conditions at home, in the street, and in the school, that tend to create or aggravate them. To do this intelligently and properly the cooperation of the public, physicians and laymen, with the authorities of the Departments of Health and Education, is absolutely essential. The public must be educated by public lectures, by pamphlets, by advice of family physicians, by visits of municipal and private workers to make their homes sweet and clean, to cultivate the proper habits of health, to clothe, feed, and give medical attention properly to their children. The public must be educated to demand hygienic and sanitary schools, clean streets, clean milk, clean living quarters, in fact, to demand the correction of all conditions unsanitary and evil.

Strange as it may appear, we physicians need education, too. We are at a crucial point, and in this struggle must keep ourselves in the front ranks or we will lose our prestige with the people. There is far too much disinterestedness, and even antag-

onism, among physicians to this movement for new school hygiene, particularly where it relates to the examinations being conducted in the schools by the Board of Health. Parents and pupils are giving their cooperation more earnestly and more cheerfully than are the physicians. And this is due to the inexorable and selfish struggle for the almighty dollar. When a child is brought to us with a card from the Department of Health, calling our attention to a defect we ourselves may be unable to remedy, too many of us are prone to censure the Department for imposing upon our valuable time. This spirit must be banished from among us. We cannot better the physical condition of the American race unless everyone of us considers himself directly interested and responsible.

However, these methods are largely preventive, and physical defects are among us now in large numbers, and must be eradicated quickly, adequately, and in a cheap and practical manner. The first step must be a thorough physical examination and periodical reexamination of all school children. In this city the Department of Health has undertaken the work of its own initiative, and its success, while highly commendable, has been limited by its inadequate means and by a lack of concentrated organization.

Last term the Department of Health made 92,000 examinations, in which 48,778 defectives were found. There were 46,089 reexaminations, and among these 10,434 had received treatment. There were registered in the schools last term 695,614. In boroughs outside of Manhattan the examinations amount to a negligible quantity. Something must be done, and at once, to make this investigation more full and efficient.

This work is not only medical, in so far as the direct examination is concerned, but also educational, in so far as it teaches parents and pupils the need of physical well-being. The preliminary examinations are made in school buildings, and often, as in preliminary examinations for defective eyes, by the teachers, and it seems reasonable to think that under these circumstances, and because the work is one of investigation and education, rather than one of treatment, it is a function of the Department of Education. At present there is a tendency to a conflict of authority. However, the labor has been begun by the Health Department, and it may be hardly fair or advisable to change horses in the middle of the stream.

After the physical examination is completed, proper notification to parents should be made of those children needing medical care, and follow up notices and visits by those in authority, to inform or persuade parents to give this care, and, in recalcitrant cases, to force this attention under penalty of the law. When parents are unable to pay for medical attention, then private or public philanthropy or the State must assume the responsibility. Dispensaries and hospitals in New York City are equipped sufficiently to care for the needy poor, especially if from their doors are kept those who are able but unwilling to pay for medical and dental care. Until this is done, needy, defective children cannot be cared for properly in hospitals and dispensaries. Financial investigations are carried on, as a rule, spasmodically and ineffectually, and a change to stricter measures will not be initiated by hospital authorities, for they are more interested in increasing the cases treated and operations performed—these large numbers look well in print—than in caring properly for these children. The initiative must come from the city or State authorities.

Each physically defective child should be indexed, the statement containing a record of diagnosis, treatment and result, and kept on file for easy reference. Until a census of the physically defective children has been made, showing the adequacy or inadequacy of present methods of eradicating these defects, free meals, free eyeglasses, free operations and the municipalizing of the medical man are hasty and uncertain remedies.

Among the many defects of school children reported, defective eyes and hypertrophic tonsils and adenoids are of first importance. In many hospitals adenoids and tonsils are removed without general anesthesia, a cruel and inhuman procedure that should be stopped at once. Such an operation without an anesthetic produces a shock so profound upon the nervous system that its effects are more harmful, I believe, than the disease itself. While the final examination of defective eyes should be made under atropin and by an oculist, preliminary examinations can be made in the classrooms by the teachers. Snellen charts are cheap, and the method of their use easily learned. If this examination is made by the teachers the attention of the school physicians can be turned more fully to the detection of other defects. It must be remembered, however, that defective eyes may have perfect vision, a fact at present little appreciated by teachers, and indeed by physicians. The Snellen test will detect defective vision. Observation and attention to symptoms, such as headaches, backwardness in study, various nervous derangements, and congested and inflamed eyelids, are necessary on the part of the teachers to detect defective eyes that may have normal vision. I think, therefore, that lectures and conferences for the teachers might be given with great benefit upon the subject of the detection of physical defects, particularly of the eyes.

In hospitals and dispensaries equipped for such work special hours might be assigned for the treatment of physical defects, and a moderate fee might be paid to the young members of the clinical staffs to carry on this work. In that event competent men will be obtained, and school clinics, as has been proposed to be established, would be an unwarranted burden on the taxpayers.

A sub-department of hygiene in the Department of Health or Education might be established, not only in this and other cities, but in every rural district, under the sole authority of an associate superintendent, who shall be physician, and have full charge not only of the discovery and correction of physical defects, but of all school matters pertaining to the welfare of school children, embodying questions of properly-constructed buildings, of playgrounds, of books, curriculum, home study, and physical training. Under such a régime there will be no division of authority, the single aim being the physical welfare of the school children. Special appropriations should be made by the Board of Estimate for its furtherance, and this appropriation should be used for no other purpose. The department should not be, as the Board of Health now is, forced to live from hand to mouth, borrowing in advance to pay for work done in the past. To earn the confidence of the people, to do its work efficiently, this new department should show clearly what the needs of these defective children are, and should place squarely upon the fiscal authorities the responsibility for success or failure in this labor of "New School Hygiene."

147 East Eighteenth Street.

A PRELIMINARY NOTE ON THE DISINFECTION OF BODY CAVITIES BY INJECTION OF SUSPENSIONS OF LIVING NONPATHOGENIC BACTERIA.

By CHARLES E. NORTH, M.D.,

NEW YORK.

BACTERIOLOGIST OF THE LEDERLE LABORATORIES.

My purpose in this paper is to call attention in general to the use of living nonpathogenic bacteria as a means of combating infections. In particular I wish to suggest the use of suspensions of living lactic acid bacteria as a spray for the nose and throat, as an injection for the colon per rectum, and as an injection for cavities where putrefactive processes and other processes which may be inhibited by these bacteria are in progress.

The several methods of immunization which are now being practised are theoretically based upon natural processes.

The administration of smallpox vaccine is based upon the fact that an infection fatal to one species of animal may be attenuated in another, and in its attenuated form may be used to protect the more susceptible species.

The several antitoxins are obtained by the overproduction of chemical substances naturally released into the circulation by the reaction of normal tissues against toxins. The surplus antitoxin, artificially produced in one species, may be injected in another for the latter's protection.

The opsonic vaccines consist of suspensions of dead bacteria. Their injection into a healthy animal is claimed to cause a reaction which produces chemical substances favorable to increased phagocytosis in a focus of infection in the animal injected.

In any proper comprehension of the term "immunity" we are bound to consider all of the means, both natural and acquired, which contribute to the defense of an organism against attacks of pathogenic bacteria.

In the methods of natural and induced immunity enumerated above, the immunity depends upon certain changes which occur in the body tissues and body juices themselves. These may be spoken of as internal defences.

I wish now to present the claims of certain external defences of the body for recognition as playing an important part in the immunity of the individual from infection. Certain nonpathogenic bacteria, because of the function they naturally perform in defending man and other animals against infection, deserve, I believe, a consideration which they have not yet received.

That antagonisms exist between various species of pathogenic and nonpathogenic bacteria has for some time been recognized by bacteriologists. Such antagonisms are in line with those which exist all through biology between different living species of both plants and animals. The "survival of the fittest" is the natural result of competition between species dwelling in the same locality.

The importation of the English sparrow has resulted in driving away most of the song birds from our city parks. The boll-weevil, an insect which causes much destruction of the cotton crop in the South, is, I understand, now being fought by another insect, harmless to cotton, which is administered to the fields, under the direction of the U. S. Department of Agriculture.

When the bacteria of typhoid fever are placed in ordinary garden earth they disappear after a few hours and cannot be recovered by bacteriological methods. But if the garden earth be first sterilized by heat and then inoculated with typhoid bacilli, they may be found alive even after several weeks. Extensive experiments of this character made by a number of observers have brought them to the conclusion that typhoid bacilli are destroyed in a short time by the living bacteria of the soil.

The souring of milk delays the putrefaction of milk because lactic acid bacteria inhibit the growth of putrefactive bacteria.

But, while the existence of various antagonisms is apparent, little attempt has been made to make use of this fact in preventive medicine. That such use is possible is not a fancy, but is strongly suggested by Nature herself. The protection afforded by nonpathogenic bacteria against pathogenic forms is a thing which is already naturally established in all men and animals. Herter has drawn attention to the uniformity of the species of bacteria normally inhabiting the intestines of man. Extensive studies carried on by him and by other observers show the colon bacillus to be constantly found in the intestine of man and of almost all warm-blooded animals. It is impossible to contemplate the universal existence of such a phenomenon without being driven to the conclusion that its existence signifies the performance of some important natural function.

Persons in robust health are comparatively free from putrefactions and other irritations of the digestive tract. Examinations of intestinal fluid show that the tract of such persons is abundantly inhabited by nonpathogenic bacteria, chiefly colon bacilli, while in the intestine of those who suffer from putrefactions these bacteria are greatly reduced. Herter and other observers are convinced that the normal inhabitants of the intestinal tract afford a certain degree of protection against strange species of bacteria.

What is true of the intestine may also be true of other body cavities. The mouth, nose, ear, vagina, and urethra are all inhabited by bacteria. Some of the bacteria represented may be pathogenic, but the vast majority are probably nonpathogenic. The normal nonpathogenic inhabitants of all these cavities may be a constant protection against infection. It is not improbable that in some of the infections which we term "mixed infections" the advent of additional species of bacteria is really a blessing in disguise. In abscesses and sinuses it may be that the mixing of the infection actually inhibits the infectious process.

Such considerations as these have led me to form the opinion that the judicious administration of properly selected nonpathogenic bacteria as a means of opposing infections has a basis in reason.

If the immunity of any body cavity is largely dependent upon the integrity of its garrison of nonpathogenic bacteria, the question arises whether this integrity cannot be maintained and the personnel of the garrison even improved by trained reinforcements administered by the bacteriologist.

Metchnikoff and his followers have already made a beginning. They recommend the drinking of milk soured by selected lactic acid bacteria for the purpose of inoculating the intestines with these bacteria. Metchnikoff's statement that the shortness of human life is chiefly due to the absorption of toxins of putrefactions from the large intestine, and that longevity can be brought about by the prevention of these intestinal putrefactions, is perhaps one of the landmarks of recent medical literature. While there has not been any great enthusiasm

among medical men to accept his philosophy, still all bacteriologists and physicians who have investigated this subject are satisfied that lactic acid bacteria do exert a marked inhibitory effect upon the bacteria that cause putrefactions.

The medical literature of Europe and particularly of France during the last few years teems with articles concerning sour milk preparations and their favorable effects, not only in curing the intestinal putrefactions of adults, but also the acute summer diarrheas and dysenteries of infants and children. The growth of interest in sour milk as a therapeutic agent has been very rapid in the United States during the past two years. Sour milk beverages have multiplied on the market, and many physicians are prescribing them in their practice. It is noteworthy that thus far the administration of lactic acid bacteria destined to reach the colon has been by mouth and in coagulated milk as a vehicle.

Most of the lactic acid bacteria refuse to grow well in any other medium than milk. At the Lederle Laboratory studies of sour milk beverages and of lactic acid bacteria have been conducted under my direction for the past year. In connection with these investigations attempts have been made to obtain a medium other than milk which is favorable to the growth of these bacteria. One of my associates, Dr. Garside, has found such a medium in lactose broth. By its use it is possible to obtain an abundant growth of lactic acid bacteria in a clear fluid that is free from other solid material. Such suspensions as these possess special advantages for the purposes I have to suggest.

My first suggestion relates to the colon. Here the value of administration of lactic acid bacteria has already been demonstrated. Many persons rebel against the drinking of sour milk preparations. It is a long journey from the mouth to the colon, and many of the lactic acid bacteria administered in this manner undoubtedly fall by the wayside.

The direct route to the colon is through the rectum. The injection per rectum of a suspension of lactic acid bacteria in a fluid medium which is clear and free from other solid matter will bring these bacteria into direct contact with the walls of the colon and its contents without interference. I believe that after the lower bowel has been cleared by the usual saline enema, such injections, made high up and repeatedly, will be found to possess important advantages over the administration of sour milk beverages. Such injections in infant diarrhea seem to me likely to be particularly advantageous. They may also prove to be of service in chronic constipation, typhoid fever, acute and chronic diarrhea, and other intestinal inflammations. By this means lactic acid bacteria may be induced to take up their residence in the colon without laying any extra burden upon the digestive organs.

As a spray for the nose and throat and the adjacent cavities, I believe that suspensions of lactic acid bacteria are worthy of serious study. Mixed infections and putrefactions are common in these regions. If lactic acid bacteria can antagonize putrefactive bacteria in the intestine, it is fair to infer that they may do likewise in other parts of the mucous membrane.

The spraying of the mucous membrane of the nose or of any infected cavity with antiseptics and germicidal solutions is at best only a superficial method of disinfection. The structure of the lining tissue of cavities is usually one which includes numerous crevices and follicles, many extending deeply beneath the surface, wherein colonies of bacteria can find shelter. The most that can be expected of a chemical disinfectant is to destroy bacteria that may be lying on the surface. A biological disinfectant, on the other hand, such as the one suggested, may fight infection with its own weapons, for where one germ can penetrate it is conceivable that another germ can follow. If an infected nasal cavity can be sprayed and implanted with a suspension of lactic acid or other nonpathogenic bacteria which are capable of antagonizing the germs causing the inflammation, a novel and promising method of treatment is afforded.

In some of the body cavities—the middle-ear, the vagina, and the urethra, and in sinuses and abscesses—it may be that the natural antagonisms which exist between nonpathogenic bacteria and pathogenic forms can be of therapeutic use. The suspensions of lactic acid bacteria may prove to be of service in these cavities, especially where putrefactive processes are causing the irritation.

It would be unwarranted for me to make any positive claims at the present time as to the value of this method of combating infection. A large amount of experimental work in the laboratory is necessary and also much clinical work before any positive and precise statement can be made as to the preparation of these suspensions or regarding the results of their administration. The study of the effect of these suspensions has already begun. A number of cases of nose and throat inflammation have been treated with apparently favorable results. One case of chronic diarrhea has been treated with apparent cure. Enough has been done to convince me that these injections deserve a fair trial and that the field is a promising one. With the cooperation of some of the physicians of this city, studies will be continued during the summer in my department at the Lederle Laboratories, and the facts as secured will be published in a subsequent article.

Acute Syphilitic Aortitis.—An interesting case was recently shown by Fein to the Medical Society of Vienna, the patient being a young man of 20 years who had contracted syphilis six months before coming under observation and complained of cardiac trouble and loss of voice. Examination revealed stenosis and insufficiency of the mitral valve and a complete paralysis of the left vocal cord. The *x*-rays showed the presence of a dilatation of the heart and a pulsating broad vessel corresponding with the aorta but no other signs of aneurysm. There were no means of deciding whether it was the mitral disease or the dilatation of the aorta which was responsible for the loss of voice. Under a course of mercury the patient's vocal cord regained its normal motility, his voice returned, and his cardiac symptoms disappeared almost completely. In making the differential diagnosis the points relied on were that dilatation of the heart has been proved to produce compression of the recurrent nerve, and that the patient was suffering from either syphilitic neuritis or acute syphilitic inflammation of the aorta, with secondary dilatation and pressure on the nerve. The *x*-rays showed that simultaneously with the improvement of the voice the dilatation of the aorta diminished until no pressure at all was exerted on the recurrent nerve. If there had been no loss of voice the aneurysmal condition of the aorta might have escaped detection and in the course of a few months would have become permanent. The author was therefore induced to classify the case as one of syphilitic disease of the aorta. He was of opinion that in all cases of syphilis showing cardiac symptoms special attention should be given to those conditions at an early date after infection, for it was possible in this stage to avert the threatened danger by energetic antisyphilitic treatment.—*The Lancet.*

AN EFFORT TO RAISE THERAPEUTICS TO A TRUE SCIENCE.

EMPIRICISM is to-day, despite the very real advances made in our knowledge of the nature and causes of disease, almost the sole basis of therapeutics. If we except a few drugs, not by any means all of the so-called specifics, we still give remedies because experience has taught us that they are "good" for certain diseases or symptoms. In the case of some we have learned, or think we have learned, why they are curative, but it is in the case of very few only that we are able to explain the how as well as the why. Practitioners in general accept the teaching of experience, or empiricism, and base their therapeutic endeavors upon that, preferring to cure their patients even if they are unable to explain how they do so; but some refuse to be guided by faith—"the substance of things hoped for, the evidence of things not seen;" they regard it as unscientific to use a remedy the action of which they do not know or do not think they know; and forgetting that "all true science begins with empiricism," they remember only the conclusion of Huxley's phrase that "all true science is such exactly in so far as it strives to pass out of the empirical stage." This is the foundation of therapeutic nihilism, and this conceit of the ultrascientific mind will no doubt continue, though perhaps in lessening degree, to exert its baleful influence upon medicine until the science of therapeutics shall have passed out of the empirical stage. That it is doing so now we have reason to hope.

There is one fact upon which both schools of medicine, the pessimists and the optimists, are agreed, and this is what our fathers called the *vis medicatrix naturæ*, nature's inherent power to overcome disease. We are learning more of that to-day, and the belief is growing that it is through the study of this protective and curative force residing in the cells and fluids of the body that we shall find an explanation of the action of drugs and other therapeutic agents, and so, by removing the stigma of empiricism, elevate therapeutics to the rank of a true science. The use of serums, of antitoxins derived from animals, is only a makeshift, and the treatment of disease will never be truly scientific and certain until we know definitely nature's method and learn how to assist the organism in its own way of combating disease. The opsonic method, the introduction of dead bacteria which stimulate the organism to the production of more protective bodies without increasing the number of noxious agents to be destroyed, is a long step in the right direction. But there are other diseases than those of microparasitic origin to be overcome, and we have yet to explain the action of drugs and of other therapeutic agents. That drugs do not, in many cases at least, act directly upon the tissues or organs to modify their action or restore their function is evident, yet that they do act in some way is equally evident. That they act by affecting the nervous centers in all cases is also an untenable assumption. We have learned that nature regulates the functions of certain organs by means of specific substances, hormones, secreted in one part of the body and carried by the blood to another part, conveying the message that it is time now for that part to act and to do its appointed share in the work of the economy. It is probable that something analogous to this occurs in disease and that drugs are hormones, or stimulants to the production of hormones, conveying the information that something is wrong in a certain part of the economy and calling upon the curative powers of the organism to exert their specific action in that direction.

This is the theory advanced and developed by Sajous in his work on "The Internal Secretions." Through a most ingenious process of reasoning this investigator has come to the conclusion that the pituitary body is the regulating organ of the economy. Its anterior lobe, he holds, contains a sensitive membrane which detects the presence of any foreign or toxic substance circulating in the blood and then notifies the posterior lobe, which is the nerve center of the adrenal bodies and the thyroid and parathyroid glands. Drugs exert a specific action upon this center, each influencing it in its own way. We cannot here develop this interesting theory or show how its author applies it to explain the action of tonics, alteratives, analgesics, hypnotics, etc. This is well done in Sajous' work above mentioned, and is summarized in a paper read at the recent meeting of the American Therapeutic Society and published in the May issue of the *Monthly Cyclopædia of Practical Medicine*. Notwithstanding the vast array of facts and the explanation of them in accordance with the theory of the interrelations of the pituitary bodies, adrenals, and thyroid, which Sajous presents in the two volumes of his work, much remains to be explained of the way in which these organs exert their selective action and render effective the specific action of the individual drugs. The theory is, however, a seductive one, and gives promise of raising therapeutics more nearly to the rank of a true science than it has yet attained through the empirical "provings" of experimenters.

HOSPITAL SHIPS.

THERE has been no naval war of sufficient magnitude since the evolution of the hospital ship really to test thoroughly the value of such an aid to the sufferers in marine actions under modern conditions. Hospital ships were certainly used in the Spanish-American, in the Boer, and in the Russo-Japanese wars, but it can hardly be said that any true conclusion as to their utility was gathered from the results of these wars. That there is a future for vessels of this description cannot be doubted,

but many questions remain to be answered before any decided opinions can be given. Whether, for instance, specially constructed ships should be used or adapted commerce vessels, are points which as yet have not been cleared up. Probably there is room for both, and this seems to be the view taken by the majority of British authorities. In fact, during war time it is likely that most dependence will have to be placed on adapted commerce vessels, but for permanent hospital use the provision of a specially constructed ship is indicated.

Fleet-Surgeon E. B. Pickthorn, R.N., recently read a paper in London dealing with the question, in which he said the following ships were needed: (1) A stationary hospital ship would be useful in providing a base hospital until other accommodation was provided, the advantages gained being a certain dependable water-supply and easy disposal of sewage. (2) A ship for the transport of sick and wounded, such as had already undergone treatment in base hospitals or stationary hospital ships. (3) An ambulance ship that would attend upon fleets in action for the conveyance of wounded to home ports. (4) A ship to accompany a fleet in which medical and surgical treatment could be undertaken for as long a period as necessary. He also suggested the advisability of entering into an arrangement with a shipping line dealing with emigrant service with a view to constructing emigrant ships in the first place for subsequent conversion into ships for the transport of sick and wounded, or ambulance ships. The other classes of hospital ships, he thought, should be specially constructed.

The objection to specially constructed hospital ships is their expense, and it is probable that the British navy will rely for the most part on adapted passenger ships. This country, however, is in a somewhat different position. She has not a large number of suitable passenger ships flying her flag, which she could charter in time of need. The number of such ships, indeed, is quite small, therefore it would appear as if dependence must be almost wholly placed upon specially built vessels. Ships of this kind cannot be built in a day, consequently they should be built in time of peace. It may be argued that good hospital ships were soon forthcoming during the Spanish-American war, and this is to some extent true. On the other hand, the merits of these vessels were scarcely tested at all, and it must be borne in mind that if we are so unfortunate at any future time as to be involved in another naval war we shall undoubtedly have to meet a more formidable enemy than in the former war. Even granting that our naval authorities can command the services of some fairly effective adapted vessels, it still would be a wise step to have two or three specially constructed vessels. To be fully prepared for war is to be on the road to victory, and a navy can hardly be said to be fully prepared for war which has not made provision for the care of its sick and wounded. Besides, the dictates of humanity call for this provision.

SALOMON'S TEST IN GASTRIC DISEASES.

In 1903 Salomon published a test by means of which he claimed it was possible to make an early diagnosis of cancer of the stomach. After a day of non-albuminous fluid diet the patient's stomach is washed and emptied at night; the following morning the empty stomach is again washed with 400 c.c. of physiological salt solution and the return fluid is examined quantitatively for albumin and nitrogen. Salomen found that in benign cases the nitrogen never exceeded sixteen milligrams per 100 c.c. of fluid and that Esbach's test showed no, or only slight cloudiness. In cancer cases on the other hand he always found from one-sixteenth to one-half a gram per mil of albumin while the nitrogen ranged from ten to seventy milligrams per hundred c.c. of fluid.

Since Salomon's publication the test has been tried in many cases and recently J. Witte published reports of twenty-seven additional cases, together with over two hundred collected from the literature, in the *Zeitschrift für klinische Medizin*, Vol. 65, Nos. 1 and 2. His findings were similar to those of other observers and while they substantiated Salomon in general, they proved that the test was not infallible, as benign cases at times showed high figures and cancer cases at times low ones. In cases of healed ulcers the nitrogen figures were always low and Esbach's solution showed only a trace of albumin at the most. Open ulcers never showed more than twenty-one milligrams of nitrogen per hundred c.c. of fluid, the highest amount of albumin found having been one-eighth of a gram per mil, even when a trace of blood was present microscopically. Blood in appreciable amount makes the test useless. Cases of chronic gastritis, without or with very much mucus, never presented more than a slight cloudiness with Esbach, the nitrogen figure always remaining below 13.3. In differentiating cases of gastrosuccorrhea and myxorrhea from carcinoma Salomon's test is liable to lead to errors of diagnosis. In these cases the amount of nitrogen was at times found to be as much as twenty-eight milligrams per hundred c.c. of fluid, while the albumin reached one-eighth of a gram per mil. In the great majority of carcinoma cases the clinical diagnosis was substantiated by Salomon's test, though in one case of nonulcerating carcinoma the nitrogen value was as low as nine and eight-tenths. At times high values of nitrogen were accompanied by only a trace of albumin and vice versa, high values of albumin then being of greater significance than high values of nitrogen. Witte believes that nitrogen amounts of over thirty milligrams per hundred c.c. of fluid together with measurable quantities of albumin positively point to malignant disease. Several cases in which a clinical diagnosis was doubtful showed high figures of nitrogen and albumin, operation having later revealed a carcinoma.

From Witte's observations we can but conclude that the test, though not infallible, is of practical value and should be made in all gastric conditions of doubtful diagnosis.

Weak Labor Pains.

The normal process of child-birth so frequently assumes a pathological aspect in the case of many women illy fitted to bear the physical burdens of maternity that a modern physician usually shares the anxiety of the patient when the end of pregnancy approaches. "Weak pains" is the untoward phenom-

enon most often observed in child-birth, and to the consideration of its causes, varieties, and treatment, Dr. W. A. Freund devotes an article in the *Deutsche medizinische Wochenschrift* of May 14, 1908. He defines as absolute weak pains those which are not sufficient to propel a normally developed child through a normal pelvis; relative weakness of the pains is made evident, on the other hand, by their inability to overcome any increased resistance to the birth of the child. Both varieties are frequently met with in the so-called infantile type of women, whose physical development is below par in every respect indeed, but is especially insufficient in the organs of reproduction. In such cases prophylactic treatment is of more value than interference in the presence of a fully developed case of uterine inertia: rational hygiene in adolescence, careful avoidance of all disturbing factors in pregnancy, encouragement of the prospective mother are the means of preventing the appearance of exhaustion and of inability to complete the act of birth. Manual or instrumental interference, too, must not be long delayed in cases of necessity, the indication for their employment being sought not in the mere duration of the labor but in the presence of any possible danger for the mother or the child if things were allowed to take their own course. Other means of treatment consist of the administration of strong coffee, of hot bouillon, and the direct stimulation of the uterus by massage and even by the use of electricity. Of drugs, the use of ergot is indicated not exactly in the presence of weak pains but in the failure of the uterus to contract firmly in the third stage of labor when the placenta has been expelled and the most serious danger, that of hemorrhage, becomes possible. Recently the extract of the adrenal gland has been used for the same indication and is always to be thought of when very prompt action upon the uterine muscle is desired. In very rare cases the only procedure offering hope in the presence of a severe hemorrhage which cannot be stopped by the usual packing of the uterine fundus lies in the immediate extirpation of the organ.

The Value of X-ray Pictures in the Diagnosis of Tuberculosis.

The older methods of early diagnosing pulmonary tuberculosis by means of percussion and of auscultation have received assistance in recent years from carefully taken *x*-ray pictures of the lung apices. Elsewhere in the present issue of the Medical Record we abstract an article of Albers-Schöneberg recounting the more frequent findings in such cases and warning against the many sources of error. Writing in the *Deutsche medizinische Wochenschrift* of May 14, 1908, Dr. Schlayer gives the clinical results of using *x*-ray pictures in diagnosis. Of 350 cases, which were observed for a sufficient period of time, 280 or 80 per cent. were suspected of suffering from incipient tuberculosis in the early examinations; 300 of them, or 85 per cent. showed evident changes in the apices in the *x*-ray pictures. Of these, the existence of active tuberculosis was proved by means of various clinical methods and the injection of tuberculin in about 58 per cent. In 28 per cent. long observation of the patient justified the conclusion that the *x*-ray findings were due to the existence of healed or, at least, inactive lesions. In 6 per cent. of the 350 cases examined, though the *x*-ray findings were negative, tuberculous infection was proved by prolonged clinical observation. These figures show the value of the new procedures in strengthening the diagnoses made by the older clinical methods. On the other hand, they serve to emphasize the truth that most of the recent direct methods of diagnosis are not to be looked upon as more final and infallible in most cases than the older methods in which inductive and indirect reasoning had to be more often employed. The newer procedures have certainly added very much to our diagnostic possibilities; but the results of them are only single, more or less valuable signs pointing to the correct interpretation of the patient's condition, but not naming directly and absolutely the disease from which he is suffering.

Breast Feeding and Development.

It seems obvious that infants who have been breast-fed should enjoy better health than artificially fed children. It is not as obvious however that the development of the child fed artificially should be more backward than that of the infant nursed at the breast, even in regard to such a function as walking, which is usually learned after the nursing life is over. That such is the fact, however, is shown by the data published by Dr. Nagel in the *Münchener medizinische Wochenschrift* of May 19, 1908. His tables show that a great proportion of the children breast-fed not at all or only for a short time are backward in the development of the teeth, as well as in learning to walk. The greatest cause for the latter failure is found in the frequency of rickets among artificially fed children. The remedy for the evil the author finds in the propaganda of the value of nursing, the spread of correct ideas in reference to rational feeding of infants and to the general hygiene of childhood, and the support of all organizations that attempt to help the women of the poor in the difficult task of bringing up their children.

News of the Week.

Army Medical Department Examinations, 1908.—The Act of April 23, 1908, reorganizing the Medical Corps of the Army, gives an increase in that corps of six colonels, twelve lieutenant-colonels, forty-five majors, and sixty captains or first lieutenants, and establishes a Medical Reserve Corps as an adjunct to the Medical Corps. Under this recent act, the lieutenants of the Medical Corps are promoted to captain after three years' service instead of five, and the increase in the higher grades insures promotion at a reasonable rate all through an officer's military career. Furthermore, applicants who are found qualified in the preliminary examination are appointed first lieutenants of the Medical Reserve Corps and ordered to the Army Medical School in Washington, D. C., for eight months' instruction.

The Medical Corps. Preliminary examination for appointment in the Medical Corps will be held on August 3, 1908, and formal applications should be in possession of the War Department prior to July 1. The applicant must be a citizen of the United States, between twenty-two and thirty years of age, a graduate of a medical school legally authorized to confer the degree of doctor of medicine, of good moral character and habits, and must have had at least one year's hospital training or its equivalent in practice. The examination will be held concurrently throughout the country at points

where boards can conveniently be assembled, and due consideration will be given to the localities from which applications are received, in order to lessen the traveling expenses of applicants as much as possible. The examination in subjects of general preliminary education may be omitted in the case of applicants holding diplomas from reputable literary or scientific colleges, normal schools, or high schools, or graduates of medical schools which require an entrance examination satisfactory to the faculty of the Army Medical School. The large number of vacancies created in the Medical Corps by recent legislation makes it certain that all successful candidates will be recommended for a commission for several years to come.

The Medical Reserve Corps. It is desired to obtain and maintain a list of qualified medical men all over the country who are willing to serve as medical officers in time of emergency, and to such men the President is authorized to issue commissions as First Lieutenants, Medical Reserve Corps. It is recognized that it will be necessary to place only a limited number of these officers on the active list in time of peace, and it is hoped that young medical men throughout the country and medical officers of the militia of the various States may be sufficiently interested to secure positions on the Medical Reserve Corps list. An applicant must be between twenty-two and forty-five years of age, a citizen of the United States, a graduate of a reputable medical school legally authorized to confer the degree of doctor of medicine, and must have qualified to practice medicine in the State in which he resides. Examinations will be held in the near future and will embrace the practical medical subjects. Full information concerning the Medical Corps and the Medical Reserve Corps may be procured upon application to the Surgeon General, U. S. Army, Washington, D. C.

Red Cross in Japan.—The sixteenth anniversary of the formation of the Japanese Red Cross was celebrated in Tokio, on June 1, by a meeting held in Hibiya Park in the presence of the Empress. The society has a membership of 1,414,225, and the value of its property exceeds seven million dollars. On its medical staff are 212 doctors, 143 pharmacists, and 668 male and 2,701 female nurses. Since the war two large hospital ships have been added to those already in use.

Babies to be Cared for.—Systematic work to insure that the infants of this city will be properly cared for during the coming summer has already been begun. In response to a request from the Health Department many societies and institutions will cooperate in the work. Milk depots are to be established, instructions to mothers will be issued, and nurses will be employed to visit at the homes. The plans for the campaign are being laid by the Conference for Hot Weather Care of Babies, of which Dr. William H. Allen, secretary of the Bureau of Municipal Research, is chairman, and Dr. John J. Cronin, medical inspector for the Board of Health, is secretary. An executive committee of seven has been appointed. Cards of instruction and information as to how to feed, clothe, bathe, and provide fresh air for the baby, will be sent out by the thousands. They will state the whereabouts of milk depots, recreation piers, and playgrounds and hospitals, and furnish other useful information. The organization of the work under a central board will permit of the division of the city into districts, with a special corps of physicians and nurses in each, and will prevent much conflict and duplication of efforts. Among the institutions represented in the Conference are the Children's Aid Society, the Trinity Dispensary, the Seaside Hospital, Bellevue Hospital, Gouverneur Hospital, Bureau of Municipal Research, St. John's Guild, the Hackley Diet Kitchen, the Presbyterian Hospital, the Children's Seaside Hospital, Roosevelt Hospital, the Junior Sea Breeze, and the Babies' Hospital.

Low Death Rate.—The Board of Health of the City of New York reports that the death rate for the week ending May 30 was the lowest for any week since 1895. The number of deaths was 1,335. The rate was 15.75 per thousand, against 16.36 for the same week last year. There were twelve deaths from typhoid fever during the week, against five for the same week last year, and 149 deaths from heart disease, against ninety-two for the same week last year. For the week ending June 6 the rate was still lower, the lowest indeed in the sanitary history of the city, being only 14.41 per thousand. The death rate for the corresponding week last year was 17.46.

Plague.—Owing to the prevalence of bubonic plague in Venezuela, the Cuban ports, with the exception of Mariel where there is a quarantine station, have been closed to vessels from that country. In Ecuador the plague seems to be well under control, though between May 8 and June 3, forty-two new cases developed. Five fatal cases have been reported from Trinidad, and every precaution is being taken to prevent its spread. President Castro has declared La Guayra free from plague and open to navigation, yet in spite of his assertion the plague continues to claim new victims daily.

Antivaccination.—The antivaccinationists of Omaha, Nebraska, have scored a victory for smallpox in the repeal by the city council of the regulation requiring compulsory vaccination in the public schools. It is stated that the enforcement of this regulation has kept out of school, during the past four months, one thousand children who will now be permitted to return. From an educational standpoint the Omaha schools have for some time been considered to have a very high standing.

Woman Ambulance Surgeon.—Dr. Mary Merrit Crawford, a graduate of Cornell Medical College, and an interne at the Williamsburg Hospital, is now on the ambulance service of that institution. Dr. Crawford is said to be the first woman to serve in this capacity in Brooklyn, though Manhattan has long since grown familiar with the sight of a medical woman on the ambulance.

Early Use of Tuberculin by the Nonfebrile Method.—The signature to the letter on this subject, in the MEDICAL RECORD of June 6, 1908, p. 949, was accidentally omitted. The letter was from Dr. F. Frémont-Smith of Washington, D. C.

Marriage Licenses.—During the five months since the first of the year, when the new marriage licence law went into effect in New York City, a total of 17,032 licenses were issued in the entire city, an average of more than 112 licenses a day. Of these, 12,715 were issued in the Borough of Manhattan.

X-ray Injury to the Eyes.—Dr. F. P. Baetjer of Baltimore was compelled to undergo an operation for the removal of one of his eyes, injured in *x*-ray work, a short time since. Dr. Baetjer began his studies on the physiological effect of the rays ten or twelve years ago, shortly after they were discovered by Prof. Röentgen. Trouble with the eyes in connection with the *x-rays* seems to be

unusual, although it is known that the eye is sensitive to the rays.

A Research Fellowship.—The graduating class of the Department of Medicine of the George Washington University, numbering 45, who received the degree of Doctor of Medicine at the commencement exercises, June 3, 1908, has announced to the university authorities the establishment by the class of a research fellowship. This fellowship will be known as the "Class of '08 Fellowship," and will have an annual fund of not less than $300.

National Association for the Study and Prevention of Tuberculosis.—The fourth annual meeting of this association was held at the Auditorium Hotel, Chicago, June 5 and 6. The scientific work was divided into sections. In the afternoon of June 5, the Association listened to a symposium on State Sanatoria, and on Saturday afternoon to a series of papers on the prevalence and prevention of tuberculosis in charitable and correctional institutions.

The Rockefeller Institute for Medical Research.—The following appointments have been made to the staff of the Rockefeller Institute for Medical Research: P. A. Lewis, Assistant in Pathology; A. I. Kendall, Assistant in Bacteriology; A. R. Dochez, Fellow in Pathology; A. O. Shaklee, Fellow in Physiology and Pharmacology. The following promotions have been made: John Auer, Associate in Physiology and Pharmacology; Don R. Joseph, Assistant in Physiology and Pharmacology; Alexis Carrel, Associate in Surgery; J. W. Jobling, Associate in Pathology; Benjamin T. Terry, Assistant in Protozoology; Donald D. Van Slyke, Assistant in Biological Chemistry; Walter A. Jacobs, Assistant in Biological Chemistry; Bertha I. Barker, Fellow in Pathology; R. V. Lamar, Fellow in Pathology.

Gifts to Hospitals.—By the will of Mary Ann Astor Woodcock of Bedford, N. Y., the Methodist Episcopal Hospital of Brooklyn receives five thousand dollars to be used for the relief of widows and orphans of clergymen and of aged and infirm clergymen.

International Medical Congress.—The American delegation to the international medical congress to be held at Budapest next year has been appointed. The list is headed by Dr. Joseph D. Bryant of New York, and includes Dr. Herbert L. Burrell of Boston; Surgeon-General Robert M. O'Reilly, of the army; Surgeon-General Rixey, of the navy, and Surgeon-General Walter Wyman, of the Public Health and Marine Hospital service.

American Gastroenterological Association.—At the eleventh annual meeting of this Association, held at Chicago, Ill., June 1 and 2, 1908, the following officers were elected for the ensuing year: *President*, Dr. Julius Friedenwald of Baltimore; *First Vice-President*, Dr. David L. Edsall of Philadelphia; *Second Vice-President*, Dr. Wm. Gerry Morgan of Washington, D. C.; *Councilor*, Dr. John P. Sawyer of Cleveland.

American Gynecological Society.—At the annual meeting of this society, held in Philadelphia, May 26, 27, and 28, 1908, the following officers were elected: *President*, Dr. J. Riddle Goffe, New York; *First Vice-President*, Dr. Howard A. Kelly, Baltimore; *Second Vice-President*, Dr. Malcolm McLean, New York; *Treasurer*, Dr. J. Wesley Bovée, Washington; *Secretary*, Dr. LeRoy Broun, New York; *Members of the Council*: Dr. George T. Harrison, New York; Dr. J. Montgomery Baldy, Philadelphia.

American Medical Editors' Association.—At the annual meeting of this association in Chicago, May 30 and June 1, the following officers were elected: *President*, Dr. T. D. Crothers of Hartford, Conn.; *Vice-Presidents*, Drs. W. A. Young of Toronto, Canada, E. W. Taylor of Boston; *Secretary and Treasurer*, Dr. Joseph MacDonald, Jr., of New York; *Members of the Executie Committee*, Drs. J. J. Taylor of Philadelphia, W. C. Abbott of Chicago, and W. A. Jones of Minneapolis.

The Rhode Island Medical Society, at its annual meeting on May 26, elected the following officers: *President*, Dr. Frank B. Fuller, Pawtucket; *Vice-Presidents*, Drs. Eugene Kingman, Providence, and Augustus A. Mann, Central Falls; *Treasurer*, Dr. George S. Mathews, Providence; *Secretary*, Dr. Stephen A. Welch, Providence. The library committee reported that the library now numbered 22,000 volumes, and that from July 1, 1907, to May 12, 1908, there had been 1,173 visitors to the library.

The Connecticut State Medical Society, which held its one hundred and sixteenth annual meeting at New Haven during the last week in May, elected the following officers for the ensuing year: *President*, Dr. Selden B. Overlook, Pomfret; *Vice-presidents*, Drs. Irving L. Hamant, Norfolk, and W. L. Barber, Waterbury; *Secretary*, Dr. W. R. Steiner, Hartford; *Treasurer*, Dr. Joseph H. Townsend, New Haven.

The Middlesex East District (Mass.) Medical Society held its annual meeting on May 13. The following officers were elected: *President*, Dr. Charles Dutton, Wakefield; *Vice-President*, Dr. Philip Hammond, Winchester; *Secretary*, Dr. Frederick R. Sims, Melrose; *Treasurer*, Dr. Josiah P. Bixby, North Woburn; *Councillors*, Drs. Corydon W. Harlow, Nom. Councillor, Melrose; Roscoe D. Perley, Melrose; Daniel C. Dennett, Winchester; *Censors*, Drs. Daniel C. Dennett, Winchester; Charles F. McCarthy, Winchester; Ernest C. Fish, Melrose; George F. Dow, Reading; Ernest D. Richmond, Reading; *Auditor*, Dr. George W. Nickerson, Stoneham; *Commissioner of Trials*, Dr. Ernest S. Jack, Melrose.

Obituary Notes.—Dr. Horace George Miller of Providence, R. I., died suddenly at his summer home in Camden, Me., on May 29, at the age of 68 years. Dr. Miller was a graduate of Harvard Medical School in the class of 1865, and had made a special study of diseases of the eye and ear. He was president of the American Otological Society from 1900 to 1902, and also served for two years as president of the New England Ophthalmological Society.

Dr. A. J. Pettis of West Branch, Mich., died on May 21 at the Harper Hospital in Detroit following an operation. Dr. Pettis was 38 years of age, and was a graduate of the University of Michigan in 1903.

Dr. John Carroll Irish of Lowell, Mass., died on May 29, from an acute attack of indigestion, at the age of 64 years. Dr. Irish was graduated from the Bellevue Hospital Medical College in 1872, and in 1877 was appointed medical examiner for his district, an office which he held at the time of his death. He was a member of the surgical staffs of St. John's and the Lowell General hospitals, and of a number of medical societies.

Dr. E. A. Deane of Montague, Mass., the oldest member of the Franklin District Medical Society, died on May 31, aged 83 years. He was a graduate of the Berkshire Medical College in 1853.

Dr. George D. Emerson of South Berwick, Me., died at his home on May 23, aged 44 years.

LETTERS TO A NEUROLOGIST.

To which are appended brief replies purporting to set forth concisely the nature of the ailments therein described, with remarks on their appropriate treatment.

VI. Education of a Mentally Defective Child.

Rochester, N. Y., Oct. 30, 1904.

My Dear Doctor:

I am writing you to ask when it will be convenient for you to see the little girl, whom, you will recall, I sent to you for an opinion concerning her condition four years ago. Although she has made considerable progress in the right direction since you saw her, it is not so great as I had anticipated in view of the sanguine position that you then took in regard to her physical and mental development. I must say, however, that the parents have done very little to carry out the plan of treatment which you outlined. They realize that it is necessary to have something done for their child and are willing, I believe, to carry out any suggestions that you make. She is now seven years old and her physical peculiarities and her attributed feeble-mindedness are making her a marked individual among their intimates and friends.

From the time of her birth, which occurred when her mother was forty-two years old, the child has always been "nervous." The mother had been ill with some kidney trouble while she was carrying the child and this illness continued after the birth so that she was unable to nurse it. During the first year the baby is said not to have slept at night except for brief periods. It was restless and in almost continual motion. When she was a year old she could not crawl or even move from the reclining position. Placed upon her belly upon the floor she could move her arms and legs but the movements were incoordinated and jerky. She began to walk when twenty-six months old, not having previously crept, but capacity for secure locomotion came very slowly. She tripped and fell even when there was no apparent obstruction or obstacle in her way. When she was three years old, I had Dr. ——, of your city, see her because of this difficulty in walking and of the jerky movements, particularly of her head, face, and upper extremities. He made a diagnosis of muscular dystrophy and gave a bad prognosis. She was then taken to Baltimore to consult Dr. ——, who interpreted her condition as a form of cerebral infantile palsy and gave a gloomy prognosis. It was soon after that I sent her to see you. Although she could then walk alone it was impossible for her to go upstairs without holding the banister, and when lying on her back she could not help herself to arise. Her speech was unintelligible. Its striking feature being lack of articulation, evident inability to coordinate the movements of the tongue, lips, and breathing to produce articulation, and almost constant grimacing, twitching of the head, blinking the eyes, and contorting the upper part of the body.

At that time she was apparently a well developed child physically. She was tall for her age, the muscles of her arms and her legs were well developed, but her chest was flat and her shoulder blades jutted out from the back. The only striking feature of her appearance was due to her eyes. They were round and small like those of a Mongolian, the internal canthus being narrow and adherent.

She has not learned to talk save a peculiar gibberish which the family are able to understand but which is unintelligible to me. She walks more securely but she has so much choreic like movement of her hands that she is unable to do anything satisfactorily, such as feeding and dressing herself. When she attempts to talk she screws her eyes, her face becomes contorted, the shoulders shrug, the body wriggles, and then she emits this peculiar inarticulate speech. She has never learned to play either by herself or with other children. I have done everything I could for her in regard to her diet and general health and I think I may say she is in fairly good conditions in these respects. The operation for removal of the adenoids has not yet been performed, but I hope to be able to persuade the mother to have it done this autumn. My chief object in sending her to you now is to get specific instructions as to how to develop her mentally. She has many qualities of mind which are as well developed as the average child of her age. She is obedient, affectionate, and docile. She knows the difference between right and wrong and although she apparently forgets very readily what she has been told they have been able to train her to a certain kind of conformity to the ordinary occurrences of daily life, but practically no real start has been made with her education. I shall be glad to get detailed instruction from you what to do.

Believe me,

Yours very sincerely, ——.

New York, Nov. 3, 1904.

Dear Doctor ——:

It is convenient for me to see your patient a week from to-day. I shall be glad to see her, even though she does not exhibit as much improvement as I anticipated, after my first examination, she should now manifest. Possibly she has not had "a square deal" from us and from her parents. These unfortunate patients are often treated by the family physician and by the neurologist alike, as dogs do the Nile. Either the parents are told that the case is hopeless or they are advised to get a teacher, whose work, pedagogical or hygienic, the physician is not fitted by training or inclination to supervise. Often the parents are warned so successfully against overstraining the child, that they do almost nothing toward disciplining or toward providing material for intellectual development. In many other instances the parents are told that the child will outgrow its present condition. Whichever attitude is taken, it is based upon an insufficient study of the existing conditions, and in the majority of instances the result is that the child reaches maturity a mental and physical defective.

I find nothing to marvel at in the fact that the majority of us are unable to supervise the training of these children and that so many of us leave to nature what properly belongs to the expert trainer. As a matter of fact, such expert trainers, as a class, have yet to be developed in this country, and in no department of pedagogy are we so far behind the procession as we are in making application of the well recognized fact, that children who do not conform to the average standard require individual instruction in order that they may properly develop. The successful trainer of mentally defective children should have unusual force of character, intelligence, insight, originality, knowledge of articulation work, such as is given to deaf mutes, and a familiarity with the modes of application of massage, baths, and calisthenics. In addition to this the trainer must be a vicarious mother and the supreme authority for the child.

You will recall that when you first sent the child to me I recommended simple exercises which could easily have been carried out by the mother, tonic baths, careful feeding, weekly weighing, and the removal of adenoids. When the child got to be five years old I suggested that it be sent to a training school for backward children, and that this school should be selected with great care, meaning thereby that it should meet the requirements of this particular case. Instead of following this advice, I am told that the mother employed a kindergartener as a governess. She could not have found one less fitted for the kind of work which was required for this child. The fundamental motive of the kindergartener is sympathy. What is needed for children such as ——, is intelligence, capacity to discipline, and sufficient insight into character to recognize that though a thing may be done advantageously in one way to-day, it must be done in a different way to-morrow.

My diagnosis of this child's condition is that she is suffering from an agenesis, or lack of development of the brain. The brain is, as you know, the central and dominant organ of the human economy which presides over the symmetrical functional development of many portions of the body. On the other hand its growth is favored or hampered by the state or condition of other fundamental parts of the body, such as the alimentary tract, the circulatory apparatus and the respiratory system, but the chief avenues of brain development are the sense organs leading to those areas of the brain which preside over the production and regulation of bodily movements. If the child cannot see, hear, smell, taste, or feel properly, it cannot acquire an adequate control of the movements of its body. On the other hand if there is some obstruction to motor expression or externalization which prevents the child from walking, running, from using the arms and hands dexterously, from moving the lips, tongue, and larynx coordinately, there is bound to be retardation in the development of its sense perception which will retard the growth of intellectual process and which will be manifested especially in disorder of attention.

You will observe that I appear to be going from the confines of medicine into the fields of education. My justification is the fact, that it is through education that neurology and psychiatry are bound to produce their best results. This child is not feeble-minded in the sense that there exists a congenital mental defect based upon an irremediable brain defect, in other words she should not be put in the category of idiotic children, although it may be thought from superficial observation of her that she is feeble-minded. It is only from the skilled diagnostician, who is acquainted with cases presenting psychological aspects similar to this child, that we can expect a differential diagnosis between inherent irremediable brain defects and those deficiencies which are the result of obstruction and deprivation.

A similar skill to that which the internist acquires from long experience with diseases and which permits him to say that such a case will recover with appropriate treatment and such a case will not, is what is demanded of the physician who essays to interpret and to treat the kind of case that we are considering. We are beginning to recognize that many states of mental and nervous exhaustion result from most trivial causes when the general vitality falls below a certain line. That which immediately precipitates this fall is oftentimes comparatively trivial. It is always the last straw that breaks the camel's back, but taking off this straw or indeed taking off the entire load will not cure the camel. The balance of the nervous system once upset is regained but slowly and no item of the patient's economy is too trivial to be disdained.

The same thing is true for these children. They are not feeble-minded, but they are psychasthenic in the narrow sense of the word. When we examine their mental and physical characteristics we can find no one thing that adequately explains their physical and mental deficiencies. Many children have larger adenoids than this child and yet their capacity for articulation is good. Still this child may remain unable to articulate until its adenoids are removed. In the same way an ordinary child possessing very little capacity of attention may learn easily without much time spent on physical exercises. This child has very defective powers of attention, inadequate control over the movements of her limbs and organs of articulation, and she will not be able to make mental progress until her attention has been first strengthened through the training of her motor powers. This can be accomplished by physical exercises, singing, articulation drill, and in other ways which will suggest themselves to the skilful trainer.

In other words, to develop this child's mind successfully, it is necessary that there should be a close cooperation of the physician and the pedagogue. The child must be under constant medical supervision, if the foundation for successful mental training is to be established and maintained. The adenoids should be removed immediately. This will enable the child to breathe through the nostrils and keep the mouth closed. This in time will remove a great deal of the idiotic expression of the face. You should carefully supervise her diet, which should consist of easily digested and highly nutritious foods. Tonic baths should be given daily. She should sleep in a well ventilated but not too cold room, and should sleep alone. It is important that she should get the full measure of sleep. The trainer naturally will see that a proper amount of rest is had during the day. If it is possible to procure satisfactory massage, she should be given some massage daily. This should be applied not only to the limbs, but also to the neck and spine. If there is any constipation, which I believe exists, this should be watched carefully and provided against through the selection of food and through abdominal massage, rather than through a resort to medication.

The educational treatment should be conducted by some skilled psychologist who has devoted his attention to this kind of work, and it should be carried out in such a way that the child is called upon to exert the best measure of energy which it possesses and still avoid overstrain and fatigue. I do not profess to have had such training myself, and I am therefore going to ask Professor Witmer of the University of Pennsylvania to examine this case with me. I shall advise that his interpretation of the pedagogical side of the case be accepted, and that his suggestions regarding the training of the child be carried out. I hold the opinion which was apparently first popularized by Apelles, that a shoemaker should give no opinion beyond the shoes.

My own experience has been that children such as this one should be taken away from home and placed in a training school where there are a few similar children. You say that the mother is not willing to have the child go to such a school, and we shall therefore have to send a trainer to her. Under the circumstances the trainer will have to

display as much diplomacy and tact in dealing with the mother as in training the child. Usually these children lack discipline of mind and conduct. They have been humored because of their defect, and they have not failed to take advantage of it. They are allowed to do pretty much as they please. In this case I learn that the child is docile, obedient, and of almost exemplary conduct. We have no reason, therefore, to look for active resistance. This will considerably lighten the task of gaining control over the child's mental capabilities. Discipline of mind is somewhat more difficult to obtain than discipline of conduct. These children show a lack of discipline through their inability to give attention to what the mother or trainer may desire them to do, through inability to do things repeatedly, whereby they become automatic, and through inability to become insensitive to distracting occurrences around them, or through complete absorption in their own meager train of thought. To give proper mental discipline and at the same time to gain the obedience and affection of the child, is an important part of the work of the trainer. She must exact that obedience which "makes slaves of men and of the human frame a mechanized automaton," for it is such a transformation that we wish her to induce. The child must recognize the trainer as the dominant influence of its life. There must be no questioning of what she does, nor of the wisdom or legitimacy of her demands. Complete, absolute, implicit obedience is her due. The child must be rendered as incapable of offering passive resistance, as she is unable to think of offering active resistance.

The trainer must realize that she is dealing with an individual and not a class. She must know that while there are certain general principles which apply to the education of these children, it is nevertheless the insight into the particular needs of the moment that affords her the best opportunity. She must know that what may be done to-day with benefit, cannot be done to-morrow, that the child may be kept at an allotted task for fifteen minutes on one occasion, when under other circumstances three minutes may suffice to bring on injurious fatigue. The capacity of the child must be carefully measured, and the trainer must appreciate that this capacity is a variable quantity. The trainer must also have a definite idea of what is the next most favorable step of progress for the child to take, and the best mode of inducing the child to make this forward movement. We cannot expect her to have a comprehension of the physiology of the nervous system, but it is not too much to ask that she shall know the physiological mechanism of movements of all sorts, and that she should attempt to apply to the individual needs of her charge the best that is known concerning the physiological and mental antecedents and concomitants of all purposive movements.

In work of this kind it is always necessary to resort to some form of physical education. This is not only beneficial to the body, but is also absolutely essential for the training of the powers of attention. All physical and mental exercises intended to train the attention and the will should be given by the trainer herself, and no part of them—it matters not how simple or elementary, or how often repeated they may be—should be delegated to others or to the child itself. To execute a movement exactly requires a definite mental image of the movement which it is desired to imitate, and a considerable exercise of the power of attention. It is extremely important in the beginning that some movement should be selected which the child can easily carry out at command. From a few simple movements of this work, the trainer should then proceed to new and more complicated movements. It is from relatively simple movements, performed with precision and at command, that the greatest mental discipline may be expected. In addition to these simple movements of precision, there should be others that are performed more freely and rather by way of amusement. These include many rhythmical exercises, which I hope eventually will overcome the incoordinate movements which this child now has. Some forms of play, in which the child may happen to be interested, should be encouraged, and used as a basis for further development, that is to say, her play should be cultivated to reach progressively higher levels. In this class come such movements as are involved, for example, in cutting out paper figures with a pair of scissors. This will not only amuse and rest the child, but will also tend to steady the movements of the upper extremities and will play an important part in training visual attention. The cutting out of various objects may also be employed as a means of training the child's imagination, or used as a medium for imparting much information.

In these general considerations I can only point to the necessity of having the work stand in some definite relation to the child's mental and physical status. Thus, every child needs coordinate physical exercises, but this child is marked out especially as having an incoordinate gait, the movements of her arms are excessive, and the articulation is very imperfect. Naturally, we desire to control these movements and perfect her articulation. Consequently we will select such activities as will not only develop will power and train the attention, but also improve coordination of the limbs and organs of articulation. That is to say, the child will first be taught to walk, then to run, to hop, skip, jump, and dance; with the hands to catch a ball, to throw, to use chalk, to hold a pencil in her hand, and, finally, to write; with the organs of articulation, first to open and shut the mouth, to move the tongue to and fro, up and down, to breathe properly, to gain voluntary control over the breathing process in association with the emission of vocal sounds, and, finally, to take the positions appropriate for perfect articulation. If the child is musical, the task is going to be a much easier one, and it should be early determined whether the child is responsive to melody, rhythm, and pitch, and has a good singing voice.

Most children like to make up and make believe. I have heard through a member of the family that this child has a great interest in dressing up in fancy clothes and pretending she is some other person. This is a natural inclination, which the trainer will undoubtedly make good use of. She will teach the child how to play better, and through her interest in "make believe" may get the child interested in stories, drama, or opera, and from this lead the child on to an interest in acting, declaiming, in people and events in the world about her, and in history.

I cannot lay too much stress upon the importance of a continual appeal to the child's aptitudes and interests. Any special aptitude which may disclose itself, as in singing, for instance, supplies a great lever. These children need encouragement. Here is a girl of eight years of age who all her life long has found herself unable to do the things which ordinary children of her own age accomplish with ease. She has found herself completely out of the

running. To bring her into competition with ordinary children will require her to pass through a very lengthy course of training, which is tedious and often discouraging. The inspiring influence of some one aptitude wherein she is better than other children, may serve to lighten the task immensely. It should be taken hold of immediately, as a means of development, for it will give her confidence and self-respect, and stimulate her ambition.

You are doubtless desirous of knowing the amount of progress that this child may be expected to make as the result of training. Considering her present condition, you will probably suspect me of excessive hopefulness and optimism when I inform you that I see no reason why this girl should not be developed into an entirely normal young woman. By that I do not mean to imply that when she reaches the age of eighteen she will have the robust health of mind and body that will enable her to commit the many indiscretions in the direction of over-eating, late hours, and excessive exercise which so many young women to-day permit themselves during the period of adolescence. She will probably always be required to be careful to avoid the excessive strains of life. Barring this, I believe that in station and gait, in conversational abilities, in ripeness of intellect, in accomplishments, and in physical appearance, she will be indistinguishable from her associates. The most difficult factor to combat is the choreic movements. These undoubtedly can be made to disappear in the legs, and with more difficulty in the arms and face. It is my belief that skilful training will enable this child to learn how to control these forced movements. The training must have due regard for the sensory as well as the motor side. What we observe are the forced movements. What we cannot observe but is probably nevertheless existent is a feebleness or weakness of sensations received from these movements. If the trainer will have due regard to the development of the perception of the sensations received from these automatic movements, she will lay the foundation for inhibitory control. The capacity of the child to gain this inhibition will depend to some extent upon her intelligence. The more intelligent the child is, and this will be developed as a result of training, the more confidently I should expect these movements to be overcome at an early period. I see no reason for believing that there is any mental enfeeblement present. We must therefore regard her as at the present time having a normal intelligence, which is unable to manifest itself owing to the many physical difficulties with which she is burdened. Open the avenues of the intellect, and we shall probably find her possessed of normal intellectual capacities. Given these, it is my belief that in from three to five years these movements should practically disappear, to recur from time to time only at moments of excessive fatigue or unusual emotional excitement. They will disappear first from the lower limbs, then from the face. The most difficult to control will probably be the movements of the arms, but it will be necessary that such control shall be gained in order that the child be enabled to write properly.

A very favorable prognosis of intellectual development can be given. The child is young enough to respond instinctively and imitatively to the suggestions of the trainer. With a skilful appeal to whatever special mental qualities reveal themselves, there can be little doubt that this child's mind will unfold year by year unexpected capabilities. The mother, I understand, asks at the present time little more than that the child be able to sit at table without being virtually a specter at the feast—in other words, she wishes her to escape notice among her friends. A great deal more than this can be done for her. In my experience it is much more common to unearth unusual mental capacity than it is to find these children to be more seriously limited than was at first supposed. The development naturally will be slow. In the first month probably very much will be accomplished. This will give rise to exalted hopes, and the first year will perhaps be spent in doing little more than making steadfast such progress as was indicated in the first month's work. The home environment is always a great difficulty for the trainer to contend against. I should estimate that this child's progress would be very nearly double what it would be if she were trained away from the influences of the home, but even with the home environment I believe that at the end of three years we shall find this girl practically normal, and with very positive indications of the kind of young woman into which she may be made to develop. I am, of course, assuming that we shall have in this work the entire cooperation of the family in carrying out the medical treatment, in making necessary changes in climate, and in following out the suggestions of the trainer. If we do not have this, we shall, of course, fall short of my expectations. My prognosis is based upon what can be accomplished under the most favorable conditions.

Yours sincerely.

Correspondence.

VISION AND MORALS.

To the Editor of the Medical Record:

Sir:—He who plants a valuable idea in the minds of his fellow men, and watches it long and weeds and waters it faithfully, though he may never live to see it as a tall and glorious tree, nor, himself, gather ripe fruit from its branches, yet has he that true satisfaction which is beyond and above the loudest plaudits and golden rewards of the world.

It has taken a long time for the idea of "eyestrain" as a major factor in many diseases to grow in our minds, and one man above all others has labored long and unselfishly to stimulate that growth. But, where once he looked in vain over the field to see the tender leaves piercing the ground, now the spreading branches are everywhere and we hear them sway and sigh in the breeze of recognition.

That much admired and much maligned book "Concerning Lafcadio Hearn," just issued from the press, deserves to be read and pondered by every live practitioner, as the latest bloom, the subtly scented flower of the seed planted long ago by one earnest member of our profession. Less direct in its lesson than his well known "Biographic Clinics" it appeals in a different way to the professional reason and understanding; it gives us a picture, graphic beyond description, of the silent, subtle, yet overpowering influence of eyesight on a man's character and work. By reason of limited vision Hearn was what he was—wonderful in a wonderful way—limited on the one hand—boundless in his ability to use the English tongue, on the other. His very lack of imagination can be traced to his lack of vision. What eye hath not seen the mind cannot conceive. No wonder he was vacillating, shiftless, uncertain in his friendships as in his purposes, for he had never come into actual, everyday, visual contact with his fellow-men, as most of us do. He never *saw* them. The flitting emotions and impulses mirrored on the faces of those around him conveyed no meaning to his semiblinded eyes. Like the totally blind, he was ever suspicious, from want of knowledge of men.

And what occurred in him may occur in many. Clear vision gives clear judgment—defective vision in its varied manifestations gives different warps and bents to the minds of its unfortunate possessors. Can we blame men for their misfortunes of birth? Can we wonder at their warped mental attitudes when their physical vision shows them only a warped and distorted world?

So the first great question concerning defective sight is its bearing on reflex disease, and this makes it incumbent on us all to think of this cause *first* in looking for causes—not last—as we too often do. And the second great question is the relation of vision and its defects to character and morals, and the problem to solve is, can we by early correction of visual defects *convert* the growing child into the straight path that leads to moral worth and soundness of intellect?

Edward Willard Watson, M.D.

Philadelphia.

OUR LONDON LETTER.

(From Our Special Correspondent.)

THERAPEUTIC NOTES — NEGLECTED REMEDIES — RHEUMATISM AND CHOREA—SALICYLATES—THE BLACKWATER FEVER EXPEDITION—ST. MARY'S HOSPITAL—SIR G. KEKEWICH AGAIN.

London, May 22, 1908.

The proposed bureau in London for collecting and distributing information with regard to sleeping sickness may now be considered as an accomplished fact. On Monday the Colonial Office announced that the Government, with the cooperation of the Royal Society and the Government of the Soudan have appointed the honorary committee, consisting of Sir West Ridgeway (as chairman), who is also chairman of the advisory committee on the Tropical Diseases Research Fund; Sir Patrick Manson, Sir Robert Boyce, Dr. Rose Bradford, Col. D. Bruce and Messrs. Clarke, Read, and Lobb of the Foreign and Colonial Offices.

The bureau will be administered by a paid director, Dr. Bagshawe of the Uganda medical staff, and its main function will be to collect information respecting the disease from all sources, to collate, condense, where necessary translate, and distribute that information as rapidly and as widely as possible among those at work on the subject. Two categories of publication will be issued—(1) scientific for those engaged in research work or in carrying out medical administration in infected districts, and (2) less technical publications for the use of Government officials, missionaries, and others whose duties require residence in such districts. One important work will be to produce a map of the whole of tropical Africa, showing the distribution of sleeping sickness and of the blood-sucking insects which are suspected of conveying it. This map, showing how far the distribution of the disease coincides with that of the different species of insects, is expected to supply valuable information to scientific investigators and to give guidance to different administrations by indicating the lines of advance of the disease and the districts which require special protective measures.

The Royal Society will provide accommodation for the bureau at Burlington House, and the Soudan Government will contribute one-fourth of the cost of upkeep.

Dr. Seymour Taylor has called the attention of the West London Society to some old remedies which he considers are too much neglected. Fashion is not altogether without influence, but it may be well to protest against interested vendors of drugs or special modes of preparing them. Pharmacists have too easily made themselves the instruments of interested persons and so far lost position as the right hands of prescribers. Dr. Taylor, in commending neglected remedies, did not confine himself to drugs. In fact, he put external applications in the foreground of his recommendations. Thus he was convinced that a seton judiciously applied in epilepsy could render the fits less frequent and less severe. Then venesection, so rarely resorted to nowadays, he has found, as is generally believed, very useful when the right heart is embarrassed. Bleeding was also useful in many cases of pneumonia, in chronic bronchitis with cyanosis, and acute edema of lung from mitral obstruction. The indication for this measure is from the heart rather than the lungs. He mentioned a case of suicidal hanging in which the external jugular was opened and life prolonged to the third day, with a suggestion that if adopted earlier the remedy might have resulted in recovery. A blister to a rheumatic joint gave great relief, and this treatment had been revived for pericarditis. Turning to drugs, Dr. Taylor said arsenic was often as good as iron in chlorosis, but must be persevered with. If it acted as a mild purgative, so much the better. He thought arsenic useful in some skin affections, but its chief use was as an adjunct to iodides in syphilides and nodes. In primary syphilis Plummer's pill, freshly made, was valuable. Pulvis basilicus or royal powder was a good febrifuge for children with gastrointestinal symptoms. In the profuse or fetid expectoration of chronic bronchitis guaicum, ammoniacum, and even copaiba, might be utilized. In acute affections of the respiratory tract antimony deserved more attention. Musk he had known to save a life which seemed to be sinking in typhoid. Dr. Seymour Taylor did not suggest that these remedies were quite discarded, but he thought most of them might be more frequently prescribed. I suppose no one will deny that in the crowd of other newer claimants they are rather out of fashion.

Let me contrast the remarks of Dr. Taylor with some statements made in the Therapeutical Section of the Royal Society of Medicine. At the last meeting Dr. Leonard Guthrie read a paper in which he maintained that the salicylates are palliative—not curative—in rheumatism and chorea in children. Large doses he found were not devoid of danger. He was told that sodium bicarbonate was an antidote, but he thought it questionable practice to give poison and antidote together. Rest in bed, isolation, and nutrition were the remedies for acute chorea—in very severe cases hypnotics. He could not recommend arsenic on the intensive method. Gastrointestinal symptoms and neuritis were too frequent. The average duration under the treatment he advised was four or five weeks. Cases running to three months were not good testimonials of treatment.

Dr. Cecil Wall endorsed Dr. Guthrie's views and referred to statistics he published in 1905. (Transactions of Therapeutical Society), and which showed little difference in results under arsenic, salicylates, and other drugs—except acetosalicylic acid, which gave a shorter period before discharge from hospital. As to aspirin, gastric disturbances would be prevented if it were only given after meals—never on an empty stomach. Further, it should be given in powder only—never in tablet form. Very large doses, such as he would never prescribe, he had known to give rise to hematuria. In severe cases, he thought sedatives useful. Chloral or chloralamide lead bromides he considered injurious. They had been known to produce mania. Any such depressant increased the condition.

So far the dangers or limits of the salicylates. Now turn to the replies put forward. Dr. D. B. Lees advocated in both rheumatism and chorea very large doses of sodium salicylate and believed they were better tolerated if double doses of bicarbonate were given at the same time. He said if unpleasant symptoms appeared, the dose should be diminished—not omitted. It was not difficult to educate a patient up to tolerating three or four times the dose that first produced disagreeable symptoms. The local use of ice in pericarditis had given him extraordinary good results. Dr. Gordon Sharp argued with Dr. Lees as to the value of large doses of salicylates, and declared he had never known them give rise to depression. He expressed astonishment, too, at the opinion against arsenic, which he had met with in London. In the North of England it was regarded as a most valuable remedy. He suggested a peculiarity in the London constitution. Dr. Gray Duncanson supported him in this, as in Scotland they found arsenic very successful. The differences might perhaps be due to differences of environment.

News has been received from the Blackwater Fever Expedition, sent out by the Liverpool School of Tropical Medicine last August. A despatch, dated Blantyre, reports that the work is progressing satisfactorily, and states that already the mechanism of blackwater fever has been put on a different footing to that which it has heretofore occupied. Drs. Barrett and York are recording their work as they go on, but it is not proposed to publish results until they return. They have not at present seen many patients passing black water.

A three-day fête at St. Mary's hospital has been held, in order to raise funds to enable the Memorial Clarence wing to be fully occupied. It was opened on Tuesday by the Princess Henry of Battenberg; on Wednesday by the Lord Mayor and Lady Mayoress. St. Mary's has always enjoyed the support of the royal family. The original foundation stone was laid by the late Prince Consort, sixty-three years ago. Twenty years later, the King (then Prince of Wales) laid the first stone of an enlargement (1865). The next extension was opened by Princess Louise. The first stone of the Clarence wing, in memory of the Duke of Clarence, was laid by the King in December, 1892. Two floors, in which the fête has been held, have so far remained unoccupied. It is hoped these wards will now be speedily furnished and used for patients.

The history of this, like that of many similar institutions, shows how ready committees are to undertake building before they have obtained the money to meet the cost.

Sir George Kekewich seems inclined to dispute the

claims of Mr. Stephen Coleridge to the leadership of the antivivisectionists. I gave you last week a sample of his slanders. He presided over a meeting last night, in which he said the association was "not a hysterical and half-crazy body of old men and women, or a lot of wishy-washy, weakminded sentimentalists." He declared they had made "full investigation," and meant to "abolish entirely the terrible cult." By way of showing how fully he has investigated the matter, it is only necessary to say he said, instead of benefiting the human race, vivisection had injured it, notably in connection with the plague in India, which could have been stamped out in seven months, but had been prolonged to eleven years by the use of serums. Just think of a number of people listening to and approving such stuff! Among his supporters, too, are members of both Houses of Parliament, etc.

The proposal to organize an International Society of Tropical Medicine has been well received. Already the German society devoted to the subject has appointed two delegates to attend the meeting to be held in London during the coming summer or autumn.

Progress of Medical Science.

Boston Medical and Surgical Journal, May 28, 1908.

A Case of Intravesical Cyst of the Ureter.—In the case reported by E. A. Codman, the chief symptom was a urine turbid from pus and bacteria. The three-glass test showed that the pus came from the bladder or kidneys. The cystoscope showed a cyst at the site of the left uteral orifice. Calculi were detected by the *x*-ray in the left ureteral region and they lay at different times in different relative positions. By an operation combining the technic of suprapubic cystotomy and pyelonephrotomy, the stones and cyst were removed. One year later there was no evidence of reformation of stones or cyst, but there persisted a mild degree of bacteriuria, phosphaturia and alkalinuria. The patient was a Russian male twenty-four years of age. The author does not regard the condition as severe enough to demand operative intervention like drainage of the kidney pelvis in the loin or even frequent lavage of the renal pelvis through the ureteral catheter. Such treatment might do more harm than good. Full details of the operation and of the chemical and microscopical examinations in the case are given in the original paper.

New York Medical Journal, May 30, 1908.

The Management of Self-Limited Disease.—W. B. Konkle says that the term "management" indicates direction rather than coercion; influence rather than usurpation; promotion of recovery rather than cure. It is not exclusive of the idea of specific treatment of disease. In every case of self-limited disease rest and sleep should be given careful attention. To this end pain of a degree that is distressing and exhausting should be controlled. Of course the heart should be assiduously, untiringly watched. A consideration of vital importance is the efficient performance of their functions by the emunctories—this cannot be overemphasized. Nutrition should be looked after; but here again natural indications should be closely studied—we should be careful not to say eat when nature says fast. Water will be the indispensable food. It is a serious matter to administer a really active dose of a potent drug. To do it intelligently is eminently proper. To do it at random is eminently reprehensible. In the management of a case of self-limited disease, immediately after the requirement of an adequate acquaintance with the natural history of such disease, comes the obligation to see that this natural history be normally developed. The single but solemn duty of the doctor here is to have the disease keep its due course, or maintain its symmetry. He can do no more than that; he should try to do no more. His province includes no less than that; he should aim at no less. As a corollary of his obligation to see that these diseases hold their course stands the further obligation to not interfere when that course is being followed. Symptom tinkering is extremely pernicious, can do naught but harm, where a proper balance or proportion between the symptoms already exists. In illustration take temperature. Not so long ago it was thought good practice to depress exalted temperature, regardless of its relationships; now it is coming to be considered a useful factor, and its deficiency within bounds is deplored.

Gonorrheal Rheumatism Cured by Seminal Vesiculotomy.—E. Fuller has performed the operation of seminal vesiculotomy 101 times without a death. Of these operations 23 have been done for the relief of gonorrheal rheumatism. In all the operation has had a profoundly beneficial effect on the rheumatism. Histories of 8 cases are given in detail. In all the 23 cases referred to above there was a seminal vesiculitis to account for the focus from which the systemic absorption originated. Of this group of cases 17 were cured as a direct result of the operation and were well when last seen. Of the remaining six two recovered and remained well until they contracted a fresh gonorrhea. Rheumatic symptoms then reappeared. Two more remained well until they indulged in sexual excesses, but when the effect of the latter passed off they again became well. Two very chronic cases relapsed, but they were a class exposed to destitution and poor living. In the acute bedridden cases the effect of the operation is most marked. In twenty-four to thirty-six hours the pain in the joints disappears, and by the fourth day the swelling. Some stiffness and some atrophy of the muscles are of course left after the rheumatic process has disappeared in these acute cases, requiring massage and passive movement. In the chronic cases pain disappears in a week or ten days, and at the end of two weeks massage can be prescribed. In the very chronic cases it may take two to three months of massage and exercise to limber up the joints which have been robbed of their function.

The Kidney in Acute Infections.—J. B. Huber enumerates the diseases in which the kidney may become infected, describes their gross environment and structure, refers in a general way to their physiology, and summarizes the symptoms of their involvement by the various infections, together with the pathological changes occasioned thereby. His experience as Coroner's physician has impressed on him the fact that patients can live with extensive destruction of organic tissue, and that the average quantity of the urine, as well as the normal quantities of its various constituents, may be greatly reduced without any visible detriment. He utters a caution against the excessive use of water on the "flushing out" principle. Certainly the patient should drink as much fluid as he desires and can comfortably dispose of, but to force it on him in unlimited quantities is certainly a mistake. For this extra work is laid on the kidney and heart. We should ease up these organs by acting on the skin and bowels. In excessive erythema, the skin cannot perform its functions, and diaphoretis then are not available.

Extraction of Cataract in the Capsule.—Three cases are summarized by W. R. Marple. Contraindications to the operator are the following: (1) Even when from its character a cataract is suitable for this operation, it is contraindicated if, after section and iridectomy, the tension of the vitreous is high or the patient is unruly. (2) In cataracts which have been ripened by Förster's method, it is best not to attempt to extract in the capsule, since the latter is very tightly stretched by the swelling of the lens masses, and is apt to rupture if such an attempt is made. (3) Cataracts which have been ripe only a short time, and have ripened quickly, as in the course of a few months, should not be operated on after this method, as the capsule has not attained sufficient strength compared to that of the zonula. These cataracts are swollen, and are said to be in the stage of imbibition. In the cases reported the indications for operation are hypermature cataract in two, and dislocated cataract and presentation of the vitreous after section or iridectomy. As to the advantages of the operation, the author notes that the vision secured in the manner followed by him is permanent, for there is no capsule left behind to subsequently wrinkle and cause deterioration of sight. The best possible vision is secured, the pupil is clean, and a secondary operation is not necessary. As to disadvantages, it may be said that there can be no doubt that loss of vitreous occurs by this method far more frequently than when the capsule is left behind. Pagenstecher operated on seventy-four cases in which the cataract in one eye was hypermature, and in the other eye simply mature. He extracted the first seventy-four with the capsule and the last seventy-four without the capsule.

The Lancet, May 23, 1908.

A Method of Suturing the Lateral Recti to Insure Greater Mobility of the Stump After Enucleation of the Eyeball.—E. Clark's method is as follows: The conjunctiva is opened all round the sclerocorneal margin and freely separated from the globe. The two lateral recti are then separately hooped up and thoroughly isolated from their attachments, clamped with a Prince's forceps, and finally divided close to the eyeball; the other muscles are divided close to the eyeball and the globe removed in the ordinary way, but especial care is taken to remove the eye as cleanly as possible. One of the lateral recti is then sutured with catgut to the lower lip of the conjunctival opening on the opposite side and the other rectus to the upper lip of the conjunctival opening on its opposite side.

A thickish silk suture is passed through the margins of the conjunctival opening in the center, and not tied, but simply twisted. This twisted thread, although enough to keep the lips of the conjunctiva in apposition, allows the egress of any blood which may accumulate within. The bleeding of the stump should be prevented or arrested by a few drops of adrenalin solution and by very firmly applying a sterilized pad. The bandage can be loosened and the dressing changed six hours after the operation, and then the socket need not be redressed for twenty-four hours. At this later dressing the conjunctiva is pulled forward by the twisted suture and the parts gently bathed with a weak carbolic or some other antiseptic lotion. The twisted suture is entirely removed on the third day. If catgut is used for the suturing of the muscles they will require no further attention. The resulting stump forms a firm bed for the artificial eye, and its lateral movements are very extensive.

The Acute Suffocative Catarrh of Laennec and Other Conditions from Which It Should Be Distinguished.—S. West says that Laennec's catarrh is a peculiar and characteristic affection, rare especially in the adult, and not generally recognized as a clinical entity. It has to be distinguished from capillary bronchitis and disseminated postbronchitic — that is, secondary bronchopneumonia. More closely resembling it are primary bronchopneumonia —that is, disseminated pneumococcal pneumonia, and, possibly, an acute pneumococcal or other bacterial bronchitis. In association with it may be placed (1) acute pulmonary edema, developing in the course of chronic heart obstruction or of acute heart failure; (2) collateral fluxion or of pulmonary failure, and (3) pneumonia which commences with widespread pulmonary congestion. A careful examination should be made in all cases, of the sputum. The author's paper is an elaboration along the lines indicated, and several illustrative cases are given. Autopsy in fatal cases shows little change. The lungs are somewhat congested and the tubes contain more or less frothy mucus. According to Laennec, the urgent symptoms are due to the rapid tumefaction of the mucosa of the medium and small bronchi. They are surprisingly like those following the inhalation of such vapors as iodine and bromine.

Malarial Cirrhosis of the Liver.—E. F. Gordon Tucker refers to a condition not uncommon in India. It is a complex state, of which the hepatic disease is the terminal event. Ascites is late, and, maybe, only slight. In the early stage, the organ is a little enlarged, and in the last stage not very small. The finely granular surface is quite distinct in appearance from hobnailed liver. The cirrhosis results from repeated attacks of malarial hepatitis and capsulitis, associated with perisplenitis and a plastic peritonitis. The adhesions resulting from the latter along with the dragging of the enlarged spleen produce extreme deformities of the stomach. There are accompanying degenerative changes in the kidneys, involving both the interstitial tissues and the renal epithelium, and the nephritis may accelerate the fatal issue. Three case histories are given. In all these cases there is invariably found a history of ill health and progressive enlargement of the spleen has extended over several years. There have been repeated attacks of remittent fever with intermissions of fair health. After two or three years of this condition the patient notices the enlargement of the spleen, which is subsequently to become so extreme. By the time this organ has reached the level of the umbilicus or has filled up the left side of the abdomen, he is suffering from all the symptoms of a profound secondary anemia, with shortness of breath after exertion, languor, and, sometimes, slight puffy swelling about the ankles. Later still there is profound emaciation, and the abdomen still further distends from the collection of fluid in the peritoneal cavity.

British Medical Journal, May 23, 1908.

Recent Advances in the Surgical Treatment of Syphilis.—D'Arcy Power presents the following conclusions: (1) Experimental evidence has shown that syphilis is due to infection with spirocheta pallida, an organism which lingers for a short time at the seat of inoculation and then rapidly spreads through the body. This organism transmitted from parent to child is the cause of inherited syphilis. (2) Many forms of arthritis formerly classed as syphilitic are due to other infective agents acting upon tissue modified by the action of the syphilitic virus. (3) Syphilitic changes in the bones, joints, tongue and other parts may occur as a result of inherited syphilis much later in life than is usually recognized. They are then the result of accidental causes, and they are often the only evidence of the inherited taint. (4) The modern treatment of syphilis consists (*a*) in the more careful administration of mercury, which is now given to cure the disease itself, and not merely to relieve the symptoms, as has hitherto been the case; (*b*) in a recognition of the limitations of the absorptive power of the iodides; (*c*) in a freer use of surgical methods to remove the products of syphilitic inflammation before the iodides are administered.

The Absorption of Ointments.—R. L. Rutton's experiments seem to indicate that lard, simple or benzoinated, and pure goose grease, are the most quickly absorbed of all the substances commonly employed as ointment bases. Petrolatum penetrates poorly unless applied with friction. Lanolin alone is absorbed very slowly, but if mixed with a more fluid material, like olive oil, it enters the skin readily. The addition of a little oil of cedar wood considerably increases the rapidity of absorption. The author's experiments were conducted on guinea pigs and white rabbits. In order to get more direct results, various tissue stains in the form of aniline dyes, were employed. These were thoroughly mixed with diverse vehicles and applied to the bare skin, the hair having been carefully clipped off. In some instances friction was used, in others the fluid or ointment was simply painted or smeared on. After the lapse of a certain period, varying from fifteen minutes to several hours, the patch was excised under anesthesia. The pieces of tissue were at once blocked, frozen, and cut, the sectioning being done in a direction parallel with the hair shafts and from below upward, in order to prevent the stain from being carried further into the tissues by the microtome blade. For the same reason the knife was cleansed with ether after each stroke. The sections were immediately placed in a filtered mixture of honey, glycerin, and water, later being mounted and examined in the same media.

Treatment of Puerperal Eclampsia with Nitroglycerin.—J. M. McCarthy analyzes fifteen cases which have come under his personal observation, together with two epileptic cases, and one of tuberculous meningitis during which labor occurred. Of the eighteen mothers, twelve were saved. Of the fifteen puerperal cases, five mothers died out of the fifteen. Standard works state the mortality to be long ago from 40 to 50 per cent., and more recently from 20 to 25 per cent. His own cases approximate 33 per cent., but if we divide the mortality into three classes, having respect to the use or otherwise of nitroglycerin, as follows—(1) cases in which it was not used, (2) used only internally, (3) used hypodermically—we get the following results: Without nitroglycerin, 5 cases, 3 deaths; with nitroglycerin, internally only, 2 cases, 1 death; with nitroglycerin hypodermically, 8 cases, 1 death. The mortality among infants was four out of fifteen, or about 26.7 per cent. And here, by the way, it may be noted that, in selecting the treatment to be employed in any particular case, the life of the infant should have careful consideration; what effect, for instance, is a prolonged period of convulsions in the mother likely to produce on the life of the infant, and, if not on its life, on its future? In the case of a patient of the Roman Catholic persuasion the first question would be a very important one. The author enumerates the various drugs which have been employed in times past. In his own hands, nitroglycerin has been the remedy giving the best results. He admits that it is quite possible that the series of cases reported, with its results, may be only a coincidence, and he urges a more extensive trial of the drug under the conditions considered.

The Internal Use of the Oil of Turpentine.—Eustace Smith says that the most palatable way of giving this remedy is to rub it up with almond mixture, sweeten the whole, and flavor with a little oil of cloves. Caution must be used with reference to the kidneys. Large doses are aperient, and so pass off mainly through the bowels. Small doses do not irritate the kidneys. The remedy is of value as a hemostatic, as in purpura, and here it must be given in aperient doses. In hemophilia, an aperient dose will often bring about a cessation of the bleeding after all other remedies have failed. Smaller doses are good for such bleedings as hemoptysis, the melena of typhoid, etc. For uritis in the adult, both syphilitic and rheumatic, it may be given in dram doses thrice daily. One of its most valuable uses is its internal administration in small doses as an antiseptic and sedative in cases of flatulent colic and unhealthy states of the intestinal mucous membrane. Also in hiccough it may be used in combination with spirits of nitrous ether. It is useful in the removal of hepatic concretions. The curative value of turpentine when given by the mouth may often be supplemented and enforced by its internal use in enema. In cases of threadworms the vermicidal action of the remedy is strikingly manifested, and it has only a salutary influence upon the mucous irritation which is a constant accompaniment of ascarides if these be numerous. It has been employed, too, in cases of catalepsy. One ounce of the oil well mixed with a pint of thin gruel and thrown slowly into the bowel acts as an

energetic stimulant to the torpid nervous system; and the injection, if followed by vigorous frictions along the spine with a strong irritating liniment, is said to be attended with very satisfactory results. In flatulent colic a terebinthinate enema, if given hot, is a welcome addition to the use of remedies by the mouth, and will often bring a severe attack to an immediate close. In the seizures of this kind which have been before referred to as common in infants the derangement is a cause of so much suffering that nothing which tends to shorten the attack should be neglected; and the injection of a dram of the oil in five or six ounces of hot barley water thrown slowly into the bowel will often put an end to the distress and send the child into a quiet sleep.

Berliner klinische Wochenschrift, May 18, 1908.

Disinfection of Stomach Tubes.—Fuld says that disinfecting stomach tubes by boiling them in water very soon damages the rubber. He has found a safe method of disinfection in keeping the tubes in 50 per cent. glycerin at 70° for twenty minutes. The rubber is made fully sterile by this method, and the tube does not seem to be harmed by the heating. It may be kept in the same fluid after the disinfection, and introduced directly without being rinsed in water.

Periosteal Fibrosarcoma.—Nunokawa describes a case of periosteal fibrosarcoma involving the left ilium. At the autopsy it was found that the numerous metastases seemed to be confined to the bones alone. The explanation of the path taken by the cells responsible for this dissemination of the neoplasm was found, however, in a number of very small neoplastic nodules in the lungs. These lung metastases were of abortive character, and could be easily overlooked with the usual autopsy technique; they were important in forming the connecting link between the primary tumor and the numerous bony deposits. The author thinks that small metastases in the lungs are a frequent source of origin for the generalized dissemination of a new growth throughout the body.

Münchener medizinische Wochenschrift, May 5 and 19, 1908.

Proteolytic Property of Sterile Pus.—Hertz has produced foci of suppuration in dogs by the injections of turpentine, kreolin, silver nitrate, and mercury. In all cases the pus obtained by such means proved to be sterile. He further tested its proteolytic activity by the method of Müller and Jochmann which consists in placing drops of diluted pus upon Löffler's serum plates. Pus due to injection of turpentine had no proteolytic action, while pus following the injection of the other chemicals possessed such action even in high dilutions. Microscopically turpentine pus consisted of lymphocytes, the pus caused by other injections contained polymorphonuclear leucocytes. The author, accordingly, corroborates the statement of Müller and Jochmann that polymorphonuclear leucocytes alone possess a proteolytic property.

Hot Irrigations in the Treatment of Chancre and Chancroid.—Zinsser irrigates venereal ulcers three to five times daily, using a strong stream of postassium permanganate in the solution of 1:4000 for this purpose. Four or five liters of the solution are used at a sitting, the temperature being raised from 45°C. in the beginning of the treatment to 50° later. Such treatment leads to discharge of the necrotic masses, disappearance of the offensive odor, and great improvement in other local as well as general symptoms. The favorable action of such irrigations is due to the mechanical cleaning of the sores, the bactericidal action of the hot antiseptic solution, and the hyperemia.

Gelatin and Salt Solution in Typhoid Hemorrhage.—Witthauer has used subcutaneous injections of gelatin and of salt solution in this condition and considers them of great value. He recommends that gelatin should be used every day or every second day while the salt solution may be injected even oftener if needed. The injections are to be discontinued after two days have passed without bleeding. Sterilized gelatin sold in glass tubes is best used for the above purpose.

Antibodies in Typhoid Bacilli Carriers.—Schöne says that the immunity of the chronic bacilli carriers must be explained by the production of antibodies which protect the mucous membranes from the bacilli. In the blood of two out of three bacilli carriers he has succeeded in showing the presence of complement-binding antibodies. None were found in persons that had had typhoid before, but did not harbor the bacilli. Schöne thinks that the demonstration of these specific antibodies may help the discovery of bacilli carriers, in some of whom neither the agglutination nor the excretion of bacilli are constant phenomena.

Pathology of Recurrent Fever.—Rabinowitz examined the organs of forty-five patients, in thirty-five of whom the diagnosis at autopsy was recurrent fever, in eight "biliary typhoid," in two Weil's disease. Microscopically, the first two groups showed similar appearances. Most characteristic changes were seen in the spleen in the shape of hemorrhagic infarcts, karyorrhexis, and deposits of fibrin. The kidneys showed parenchymatous changes, and the cells of the liver and of the heart stained badly. Free and intracellular spirilla were found in the patients dying in the first and second crisis of the fever or in the first apyretic period, being distributed through many organs. The organisms were oftenest observed in clumps and foci, and in the spleen such clumps were found near the areas of fibrin and of karyorrhexis. Their number was diminished in the second paroxysm, and after it they could be no longer demonstrated.

Von Pirquet's and Moro's Tests Compared.—Emmerich has used Moro's tuberculin ointment for the diagnosis of tuberculosis in 241 patients, in 121 of whom the v. Pirquet cutaneous test was also applied. He concludes that fewer patients, clinically free from tuberculosis, give a positive reaction with Moro's ointment than with v. Pirquet's test; that the ointment test is much easier applied; that it fails to produce a reaction in progressive tuberculosis much sooner than the cutaneous test; that latent foci cause a positive reaction with the ointment, which is, therefore, of little use in adult patients.

Deutsche medizinische Wochenschrift, April 29 and May 14, 1908.

The Practical Uselessness of the Ophthalmotuberculin Reaction.—Klieneberger has tried the Calmette test in fifty-two cases of tuberculosis, in which bacilli were demonstrated in the sputum. In nineteen patients, or 63.5 per cent., reaction was observed, the greater number of negative results being given by patients in the third stage of the disease. Of the one hundred and twenty-three persons with suspected tuberculosis sixty-eight, or 44.7 per cent., gave a positive reaction; of the 239 persons in whom no tuberculous infection could be diagnosed clinically, fifty-six, or 23.5 per cent., gave a positive reaction. The author thinks the ophthalmoreaction has no prognostic significance; that a positive reaction is not a sure sign of the existence of tuberculosis; that negative results are of still less value. He prefers the cutireaction of v. Pirquet, because it is not dangerous and is less liable to error. Of seventeen tuberculous patients of his series, fourteen gave a positive cutaneous reaction; of eighty-six suspected cases forty-five gave a positive reaction; of twenty-three cases in which no tuberculosis was suspected, sixteen reacted.

Prophylaxis of Syphilis.—Uhlenhuth and Weidanz say that they, with other authors, have succeeded in showing that the arsenic preparation atoxyl is both a curative and a preventive remedy in syphilis, the latter action being demonstrated on apes inoculated with the disease. They have further compared the relative value of atoxyl and of mercury as preventives of syphilitic infection by many experiments on rabbits. With the use of atoxyl they were able to prevent a specific keratitis in any of some thirty or forty animals used, though the controls showed the virulence of the material employed. No such action could be satisfactorily demonstrated in the case of mercury and its value as a prophylactic remains undecided. The authors disclaim any intention of claiming that their results deny any possible preventive value of mercury in human infections with the virus of syphilis, but are of the opinion that the work of Metschnikoff, Salmon, and others show that atoxyl even here is a better remedy than mercury.

Apex Tuberculosis in "X"-ray Pictures.—Albers-Schöneberg says that the small foci of infiltration may be discovered at a time when they give no physical signs on percussion, and few or none on auscultation. Normally, the apex presents a black shadow with whitish streaks made by the vessels. The pathological findings may be as follows: There may be well-marked diffuse shadow without the blood-vessel streaks; the shadow may be evident only in the upper portion of the apex and present a linear demarkation from the rest of it; cloudlike, often confluent spots may be seen; distinct, separate, lenslike foci; distinct, deep shadows, probably due to calcified spots; unilateral white border running parallel to the lower edge of the second rib. The sources of error are found in pictures showing no contrast; in over-exposed plates, which show the vertebra very distinctly, while the apices appear as very dark shadows without vessel streaks; in under-exposed plates, where bone and lung tissue cannot be differentiated; in lack of sharpness in the pictures. Other sources of error are found in the local changes of the tissues overlying the lungs, and in the bad position of the patient during the process of taking the pictures. Only technically perfect *x*-ray pictures are useful in the diagnosis.

Society Reports.

AMERICAN MEDICAL ASSOCIATION.

Fifty-ninth Annual Session, Held in Chicago, June 1, 2, 3, .. 4, and 5, 1908.

(Special Report to the MEDICAL RECORD.)

(*Continued from page 968.*)

HOUSE OF DELEGATES.

Wednesday, June 3—Third Day.

Report of the Reference Committee on Sections and Section Work.—Dr. LEARTUS CONNOR of Michigan, Chairman. The resolution presented at the previous day's session to provide for the establishment of a section on the science and art of diagnosis was reported upon adversely. The report was adopted.

Report of the Reference Committee on Legislative and Political Action.—Dr. C. S. BACON of Illinois, Chairman. The committee reviewed the work of the Committee on Legislation during the year. Under the head of national legislation it recommended the adoption of a resolution providing that, in view of the great importance of the duties of the dental corps in both branches of the military service of the country, action should be taken, in accordance with the views of the Secretaries of War and of the Navy respectively, to obtain legislation at the next session of Congress looking to the establishment of these corps on a commissioned basis. The resolution was adopted.

The resolution presented at Tuesday's meeting providing for a special committee to seek such a modification of the patent and trade-mark laws as to prevent the acquirement of proprietary rights in pharmaceutical preparations was favorably reported on, and was adopted by the House.

The draft of a model law for registration of births and deaths was recommended to be approved and communicated to constituent bodies with a view to its adoption by such States as now had no provision for keeping vital statistics. The recommendation was adopted.

The proposition for the establishment of State legislative committees to act in connection with the Committee on Medical Legislation was recommended for approval, and was adopted by the House.

The resolution presented at Tuesday's session by Dr. Sanders of Alabama, to seek a national charter for the Association, did not have the support of the committee, in view of the fact that repeated efforts in the past toward the same end had been futile. This adverse report was adopted.

Report of the Reference Committee on Hygiene and Public Health.—Dr. W. N. WISHARD of Indiana, Chairman. On the question presented by the Board of Public Instruction in its report as to whether articles for the instruction of the laity, under the authority of the Board, should or should not be signed by the author, the Reference Committee recommended the adoption of a resolution expressing the sense of the House of Delegates that the name of the writer might be published at the discretion of the Board, but that neither his place of residence nor positions held by him should appear.

Dr. J. F. PERCY of Illinois was convinced that the medical profession had gone too far in its fear of self-advertising. He considered that the articles under consideration provided an ethical way of reaching the public. So far as the main purpose of the effort was concerned, undoubtedly the names of the authors should be published with the articles, and he did not think the fear of advertising an adequate argument against such publication.

Dr. WILLIAM T. SMITH of New Hampshire believed that articles should either be signed by their authors or should be indorsed by the Board of Public Instruction. On the suggestion by a member that the matter of publishing the names be left altogether to the discretion of the Board, it was pointed out on behalf of the Committee that the Board wished a definite expression of the sentiment of the House as to whether the names might be published. The Board would still retain discretion in the matter.

Dr. A. K. WEST of Oklahoma thought that the designation of the positions held by the writer should certainly be given. The name of a leading man talking to the people of his State would have much more weight than the mere publication of an unsigned paper.

Dr. OLIVER T. OSBORNE of Connecticut asked why the committee thought the name only and not the title of the writer should be published. Explanation was made that the committee, realizing the great differences of opinion which existed in the profession upon the subject, made this recommendation in the nature of a compromise between extreme views. The committee desired to approve the main question, and to leave the matter of amendments along the line of signature to the House of Delegates, expecting that the matter would be the subject of considerable debate which would develop the sentiment of the Association. After considerable discussion, the question was recommitted to the Reference Committee for the formulation of a new resolution, which was later reported to the House and adopted, as follows:

"Resolved, That it is the sense of the House of Delegates of the American Medical Association that the papers authorized by the Board of Public Instruction shall bear the statement of such authorization by the American Medical Association, and may be signed by the author."

The Reference Committee recommended that the report of the Committee on Ophthalmia Neonatorum be adopted, and that the committee be continued for another year, to carry on its work as outlined in its report. The recommendations of the Reference Committee were adopted.

Report of the Reference Committee on Constitution and By-laws.—Dr. GEORGE W. GUTHRIE of Pennsylvania, Chairman. The committee reported favorably an amendment to the By-Laws providing that the Sections on the Practice of Medicine, Surgery and Anatomy, and Hygiene and Sanitary Science should elect the orators on medicine, surgery, and State medicine, respectively. After the addition on the floor of the House of a proviso that the annual addresses on the above-named subjects should be delivered by the orators before their respective sections, the amendment was adopted.

Report of the Reference Committee on Miscellaneous Business.—Dr. STUART MCGUIRE of Virginia, Chairman. The committee had given consideration to the report of the Committee on the Davis Memorial and to the supplementary statement presented at Tuesday's session by the chairman, Dr. MARCY. The question of an appropriation toward the memorial fund had previously received the careful attention of the Board of Trustees, who had considered that to make such an appropriation would establish a dangerous precedent and hence be unwise. The Reference Committee recommended that the Board of Trustees be upheld in its decision, and the recommendation was adopted.

On the question as to whether the Association should request of State societies that they adopt a policy identical with that of the *Journal* to exclude from their organs all advertisers whose products had not been indorsed by the Council on Pharmacy and Chemistry, the committee recommended favorable action.

Dr. WALTER CHEYNE of South Carolina advised delay, saying that for the present the matter should, he thought, be left to the Association of Medical Editors, and that the House of Delegates should let the matter go over for another year.

Dr. MCCORMACK pointed out that almost this iden-

tical resolution had been adopted a year ago, except for the formal communication of the recommendations to the State societies. It was a matter of such vital importance that if the State societies should not accede to the sentiment of the association thus expressed, the House of Delegates should next year, he thought, instruct the State bodies to obey its injunction.

Dr. Oliver T. Osborne of Connecticut said if the action was one which should be taken at all it should be taken now.

Dr. A. K. West of Oklahoma said that the work of the Council had been conservative; that its purpose had been to assist, not to break down, legitimate business, and to attack only dishonesty. The recommendation of the committee was adopted by the House.

Dr. G. Lane Taneyhill of Maryland submitted resolutions whose purpose was to divert the contributions thus far made to the Davis memorial fund from the original purpose of a monument and to establish therewith a fund to be used in the encouragement of scientific medical research, thereby establishing a greater and more lasting memorial to Dr. Davis than one of stone. The resolutions were referred to the Reference Committee on Miscellaneous Business.

A resolution adopted by the Section on Obstetrics and Gynecology was presented to the House of Delegates requesting that that body appoint a standing committee to be called the National Committee on Criminal Abortion, whose duty should be to investigate the laws of the United States and of the several States bearing on the matter of criminal abortion and to seek to bring about the adoption of uniform and adequate legislation upon this subject. The resolution was referred to the appropriate reference committee.

Another resolution from the same section recommended to the House of Delegates the advisability of establishing some system of instructing the youth of the country on sexual subjects. Discussion brought out the fact that the Board on Public Instruction favored the presentation of such information only through the attending physician. The resolution was referred to the Board on Public Instruction.

Dr. H. L. E. Johnson of the District of Columbia presented to the House a number of matters bearing on the practice of medicine in the District of Columbia, discussed the need of a general revision of the medical practice act so as to exclude from the practice of medicine in Washington all who were not properly qualified professionally and ethically. He mentioned the effort which had been made by the two chiropractic operators to have established a board of examiners in their art, which effort had so far been successfully checked. These matters were referred to the Reference Committee on Medical Legislation.

Dr. William H. Welch of Maryland called attention to the fact that no action had been taken upon the invitation from the American Association for the Advancement of Science that the American Medical Association appoint two of its members to become members of the Council of the former body. Dr. Welch pointed out that the American Association for the Advancement of Science represented for all sciences save medicine just what the American Medical Association represented for medicine. He therefore urged the acceptance of the invitation. The House thereupon took favorable action.

Dr. L. S. McMurtry of Kentucky presented a resolution endorsing the candidacy of Dr. Charles A. L. Reed for the United States Senate. This resolution was received with much enthusiasm, and was adopted by a unanimous standing vote of the House.

Dr. J. N. Hall of Colorado presented a resolution commending the Public Health and Marine Hospital Service for its services against plague and yellow fever in California and Louisiana, and recommended that the functions of that service be so amplified as to cover all matters which should come within the province of a department of public health.

Dr. W. T. Sarles of Wisconsin offered to the House a resolution adopted by the Northwestern Alumni, at the instance of Dr. John B. Murphy of Illinois, expressing the sense of that body that the time had arrived when a department of public health should be established by the United States Government. This and the preceding resolutions were referred to the Reference Committee on Legislation and Political Action.

On behalf of the Section on Hygiene and Sanitary Science a resolution was introduced recommending that ophthalmia neonatorum should be classed with contagious diseases and so treated by health authorities. The resolution was referred to the Reference Committee on Hygiene and Public Health.

Dr. C. S. Bacon of Illinois presented a resolution providing that the chairman of the Committee on Organization should be associated with the Committee on Medical Legislation and at its request should represent the latter committee in the advocacy of medical legislation before various legislative bodies during the ensuing year.

Thursday, June 4—Fourth Day.

Election of Officers.—The following officers were elected: *President,* Col. Wm. C. Gorgas, U. S. Army; *First Vice-President,* Dr. Thomas Jefferson Murray of Montana; *Second Vice-President,* Dr. John A. Hatchell of Oklahoma; *Third Vice-President,* Dr. Thomas A. Woodruff of Illinois; *Fourth Vice-President,* Dr. E. N. Hall of Kentucky; *General Secretary,* Dr. George H. Simmons of Illinois; *Treasurer,* Dr. Frank Billings of Illinois; *Trustees,* for the term ending 1911, Dr. Wisner R. Townsend of New York, Dr. Philip Mills Jones of San Francisco, and Dr. Wm. T. Searles of Sparta, Wis.

Atlantic City was selected as the place of meeting in 1909.

SECTION ON ANATOMY AND SURGERY.

Tuesday, June 2—First Day.

Local Applications in Surgery.—Dr. James E. Moore of Minneapolis read this paper. Most wounds healed by the unaided efforts of nature. Local applications had for many years been used without proof of their usefulness. A failure on the part of the profession to accord to nature the credit for cures which they unjustly ascribed to themselves and their medicaments had done much to encourage and justify in the eyes of the public at least the developments of such cults as Eddyism, Dowieism, etc. Even the value of dressings had been greatly overestimated. Too much meddlesome surgery had been practised in the case of suppurating wounds. Irrigations, even if unirritating, tended to stop the development of granulation tissues. Ninety-five per cent. phenol followed by alcohol in two minutes was the best treatment. The use of heat and cold had been much abused. Misplaced faith in local applications as a substitute for operative intervention had lost many precious lives.

Dr. H. A. Royster of Raleigh said he believed that there were certain well defined uses for local applications which were shown to be free from harm.

Dr. Ochsner of Chicago said that the value of most harmless applications lay in the fact that they kept the applier from doing something worse. Whatever benefit might be ascribed to them undoubtedly came from rest and hyperemia.

Dr. J. B. Murphy said that stress should be laid upon the desirability of leaving wounds alone, there being no worse instance of the failure of doing so than the milking of abscesses.

Dr. R. F. Weir of New York said that wounds required rest and cleanliness. Personally he said that he considered painful swellings required for their successful treatment

moisture and heat. It might not do good for the inflammation but it helped the tingling nerves.

Dr. A. B. Bevan of Chicago could not agree with the German pathologists as to the entire uselessness of bland washes. He thought that wet dressings improved the drainage and gave comfort. He was also coming to the occasional use of ointments for the relief of pain.

Dr. Jackson of Kansas City said that the prime element in moist heat was not its hyperemic action but the fact that it exercised a selective static action upon the lymphatics. This could be proved in a homely way by the fact that the first action of heat upon the skin was to blister. Heat produced in other words an outward flow of lymph. Heat was an emphatic phenomenon and was therefore indicated in infections but contraindicated in contusions.

Bier's Hyperemia.—Dr. J. F. Binnie of Kansas City read this paper. He said that granulation tissue was the first element in resistance and that hyperemia was the second. Prolonged research had given him much faith in the Bier's treatment and the results were gratifying. An important point was that the suction of the cups should not be sufficient to cause stasis. Formerly the pain of inflammatory swellings was supposed to be due to the mechanical stretching of the tissues. The fact that Bier's cups stopped it suggested that pain was due to the high specific gravity of the exudate. The specific gravity of the pus in an acute abscess was very high while that of the pus in a so-called cold abscess was not very different from that of plasma. This further suggested that pain was largely due to the difference in specific gravity.

Dr. M. G. Seelig of St. Louis said that cups were less dangerous and more successful than tourniquets.

Dr. Eisendrath of Chicago said that the Bier treatment was particularly successful in certain forms of acute arthritis. In tuberculous arthritis the results were equally good. In acute streptococcic infection the treatment had little effect. It had, however, a profound effect upon the healing of fractures, and lastly it was of distinct value in preventing infection after crushing injuries.

Dr. J. B. Murphy of Chicago said that Bier's treatment had been too little used and too often misused.

Wednesday, June 3—Second Day.

Lantern Slide Demonstration of Cranial Operations.—Dr. Harvey Cushing of Baltimore read this paper. It was not so long ago, he said, when the physician as the man of skill and intelligence directed the surgeon who was then simply the artist who could handle a tool. Modern surgery had done much to change this, and indeed in the commoner forms of surgery the great surgeons were all great diagnosticians. Cranial surgery was as yet in process of evolution. Until now it had occupied a position very similar to that held by old-fashioned abdominal surgery—the neurologist had furnished the brains and the science while the surgeon furnished the mechanical skill and art. A great change was taking place in that the neurologist of the future would of necessity no longer be a mere diagnostician but a neurological surgeon. As to the technique of cranial operations it was well known that the cardio-respiratory centers in the medulla were often impaired functionally by intracranial pressure. Some operators had advised the use of rectal anesthesia, but there had been elaborated at the Johns Hopkins Clinic a very complete method whereby all possibility of infection was done away with, the ether being given in the ordinary manner. Decompression operations done intermuscularly through the temporal muscle were proving satisfactory in two very important ways. Allowing as they did the protrusion of a large amount of the silent area of the brain, they gave in the first place not only relief from pain but allowed of restitution of functions subverted from the normal by intracranial pressure. At first it was thought that all one could hope for from the decompression operation lay in the mere palliative and temporary relief, but now that some of these operations had been done a considerable length of time ago it was beginning to be observed that a second and equally important outcome was to be expected of decompression in certain cases. Already there were returning to the hospital a number of decompression cases in which primary operations has permitted a hitherto unlocalizable tumor to develop sufficiently to give rise to definite focal symptoms. This diagnosis, now easy, was impossible at the time of the primary operation. A secondary operation enabled the successful removal of the growth. He called attention to the great danger of lumbar puncture in cases of brain tumor situated below the tentorium. After removal of the water pressure tumor pressure crowded the medulla down into the foramen magnum, and in one case at least so harshly as to stop the functions of the medullary centers and cause death.

Dr. Frank Hartley of New York City read a paper on the same subject. He demonstrated the special instruments which he was in the habit of using and in particular the direct-acting circular saw. This was capable of complete sterilization, and in the hands of one familiar with it proved a valuable addition to the armamentorium of cranial surgery. He then demonstrated by lantern slides the various bone flaps which he had found of practical value in entering the skull, and showed also the method of localization which he had found most constantly satisfactory.

Dr. C. H. Frazier of Philadelphia read another paper in which he considered the vertical position of the patient both as regards the control of hemorrhage and as facilitating the approach to the part as a point of great technical importance. He showed a great number of photographs of patients upon whom decompression operations had been done and stated that he felt reasonably sure that the release of pressure afforded by this measure might in some cases hasten and in others retard tumor growth. In one photograph shown the decompression tumor had grown at such a rate as actually to burst its bounds.

Intracranial Complications of Ear and Nose Diseases.—Drs. James F. McKernon and C. G. Coakley of New York City presented this paper. Dr. McKernon said that there was a very distinct classification of the complications in the order of their recurrence. By far the most frequent was pachymeningitis, epidural abscess being a close second. As to the symptoms, headache, which was exaggerated by exercise, was suggested, but the diagnosis was rarely made until the time of operation. The treatment consisted of the removal of all diseased bone. He regarded the differential blood count as very important; the leucocyte count furnishing only an index of the patient's resistance. Blood cultures he regarded as the most important of all laboratory aids to diagnosis and believed that this method would soon surpass all others.

Dr. Coakley said that cases of intracranial complications arising from rhinological lesions were very rare. There were three paths by which it was possible for infection to reach the brain from the nose and accessory sinuses, viz., by the blood-vessels, by the lymphatics, and by direct necrosis of the bony walls. Out of 200 cases he had observed but three in which the posterior walls of the frontal sinus were involved. The inferior wall, however, not infrequently suffered considerable bony destruction. In the ethmoidal cells there were three types of disorders, viz., suppuration, polyp formation, and cysts. One reason that the literature on the subject was so meager was because cases of painless sinus infection were not as a rule regarded either by the laity or by physicians as in any way as serious as a similar lesion occurring in the ear. Furthermore, the nasal cavities communicated with that portion of the encephalon which lay in the interior fossa of the skull. Not so the ear which communicated with the middle and posterior fossæ. It was well known how much damage could be done to the interior portions of the brain without symptoms and also how little could be done to the middle and hinder portions without serious symptoms at once

arising. As to operative technique, he preferred the so-called ethmoidal route which enabled one to work parallel to the floor of the cranium, as it seemed much safer than the maxillary route. The operation in acute cases should permit of absolutely no delay.

Dr. J. B. Murphy of Chicago said that ligation of the external carotid in middle meningeal hemorrhage would often be a life-saving procedure. The closure of the foramen of Magendie had a very important bearing upon atrophy of the optic nerve. It was possible to resect a V-shaped piece of the velum and reestablish the opening.

Dr. Jansen of Germany corroborated Dr. Coakley's findings, stating that in 1,200 cases of rhinological lesions only three developed meningitis, and in the entire series there were no cases of brain abscesses secondary to the nasal trouble.

Dr. Willy Meyer of New York said that the occipital fossa tumors were chiefly under discussion, and that it was gratifying to learn that so much progress was being made in the technique for successfully reaching the region, because of all tumors these were the easiest to localize on account of auditory and facial nerve involvement.

Dr. Robert F. Weir of New York said that from 1875 to 1880 he had entered hopefully and enthusiastically upon this field of surgery. At the end, however, of six years of discouraging failures he gave up cranial surgery, concluding that his energies might better be spent elsewhere. Most of the lesions seemed at that time to be either tuberculous or malignant. Three things of value were handed down from this period of work, viz., the rubber band for scalp compression, the celluloid plates, and the decompression operation.

Dr. Cushing said that the work was new and difficult to discuss. Some points, however, were sufficiently well fixed to justify great encouragement and hope for the future. What was to be done inside the skull case seemed to him of much greater importance than the mere technique of effecting the entrance. To this end a thorough knowledge of neurology was absolutely essential in those attempting to do cranial work.

Dr. Frazier said that the technique of operations for post-tentorium lesions was not yet evolved. The two-stage method of operation had evidently been abandoned. He warned against the danger of decompression operation taking place in injudicious hands of indicated radical tumor removal.

Observations on the Thyroid and Parathyroid.—Dr. Herman Tuholske of St. Louis read this paper. He said that even to-day certain authors still maintained the morphological and functional entity of these two glands. The vast mass of modern observations, however, forced one to the belief that they were separate entities and a part of the general glandular system of the body. It had been observed that if the thyroid veins were tied in dogs the glands, at first swollen, eventually underwent a certain amount of atrophy. Acting upon this observation he had ligated the veins in a man the subject of violent exophthalmic symptoms.

Dr. Charles Mayo said that living pathology, thanks to modern technique, could now be studied. The circulation of the thyroid was the most perfect of all organs save the brain. All glands had an associated function, the hormones being the interglandular messengers. The preservation of the parathyroids did not seem to him as vitally important as certain observations would lead one to think, because in over 700 operations upon the thyroid no case of tetany had as yet developed.

Dr. A. J. Ochsner of Chicago said that the problem relating to the surgery of exophthalmic goiter resolved itself into an interpretation of the double question, when and how. The two important technical points were to minimize the trauma and the shock.

Decapsulation of the Kidney.—Dr. Samuel Lloyd of New York read this paper. Chronic nephritis, he said, was always to be treated by decapsulation. The functional activity of the kidneys was always increased by the operation, and in about 33 per cent. this improvement was permanent.

The Diagnosis at Operation Between Chronic Ulcer and Cancer of the Stomach.—Dr. F. B. Lund of Boston read this paper. Even with the abdomen opened there were many cases of indurated ulcer of the stomach in which differential diagnosis between benign and malignant conditions was impossible. There were cases in which diagnosis of early cancer was important because it enabled thorough removal. There were, broadly speaking, two classes of cases. The first included indurated ulcers which were movable and which might be benign or malignant. In this type, even if benign, gastroenterostomy was often useless, partial gastrectomy being indicated. Indurated ulcers of the pylorus often extending from the duodenum and adherent to the pancreas or left lobe of the liver, formed the second class. These were usually benign, excision was difficult, gastroenterostomy was safe. In the first class excision should be done regardless of laboratory findings. In the second these were important and usually reliable.

Ulcer of the Duodenum.—Dr. William J. Mayo of Rochester, Minn., read this paper. Duodenal ulcer had been shown recently to be more frequent than gastric in a percentage ratio of 69 to 31. The difference in the sexes was marked, 77 per cent. of duodenal ulcers occurring in males, and 23 per cent. in females. The contents of the duodenum were relatively sterile. This might account for the fact that although there was a high percentage of perforations in duodenal ulcer the death rate was low. The perforating ulcer was divided into acute, subacute, and the chronic. The latter comprised more than one-half of the total number. The general operative mortality was 2.8 per cent.

Dr. A. H. Ferguson of Chicago said that as a rule diagnosis was made at the time of the operation; that abdominal surgery had now reached such a point of development that all patients having definite gastric symptoms should be explored early.

Dr. Parker Syms of New York emphasized the importance of early diagnosis and of early operation. He gracefully admitted the value of gastroneterostomy as practised by Mayo, but suggested that the views of Rodman as to the conservative use of the more radical operation, pylorectomy should be given more than passing heed.

Dr. N. B. Leggett of New York demonstrated a series of experimental gastroenterostomies which had been made on dogs at the Surgical Research Laboratory at Columbia University. These dogs had been fed a string to which a BB shot had been attached, the other end being made fast in the pharynx. A lantern-slide exhibition demonstrated the courses which these strings might take. They might obviously go in one of four directions, viz., through the pylorus and on into the gut; through the pylorus and back into the stomach, a direct cycle; through the stoma and on into the gut; through the stoma and back into the stomach again *via* the pylorus, a retrograde cycle. The position of the stoma, whether at the most dependent portion of the stomach or near the pylorus, had no practical effect upon the frequency with which it was used. About half the strings passed through the stoma, the other half through the pylorus.

Dr. Mayo said that, as Dr. Leggett had shown, the mere doing of a gastroenterostomy without first making a surgical diagnosis might do great damage to the patient. He emphasized the need of early operation and said that no form of medical treatment would ever cure a pylorus contracted from ulceration.

The Surgical Diseases of the Pancreas.—Dr. John B. Deaver of Philadelphia read this paper. He spoke of the pathology of chronic pancreatitis, stating that infection was the most important point in the etiology of pancreatic disease.

Pancreatitis in Its Relation to Gallstone Disease.—

Dr. W. D. Haggard of Nashville read this paper. The pancreas was involved in 6 per cent. of all cases operated upon for disease of the biliary passages. Eighty per cent. of all pancreatic diseases were the result of or coincidental with gallstones. The head of the gland was invoked seven times as often as the entire gland. Nearly two-thirds of the common bile duct was surrounded by the head of the pancreas. Swelling of this probably caused most cases of obstructive jaundice.

Is Death in High Intestinal Obstruction Due to the Absorption of Autotoxic Glandular Secretions?—Dr. J. W. Draper Maury of New York read this paper. He detailed a series of experiments which had been conducted during the past year at the Surgical Research Laboratory at Columbia University. The experiments had been made on dogs under ether anesthesia. Obstructions in the oral portion of the small intestine had given certain interesting results. The twine triangular ligature had been used to create a potential gastroenterostomy, and this gave in all cases drainage of the stomach in a uniform average time. Obstruction oral to the papilla to the vater did not kill the animals whereas obstruction just aborad to it did kill them. If the obstruction were made 35 cm. aborad to the papilla the animals would live. If the obstruction were made within the first 35 cm. just referred to and if in addition the bile were shunted by cholecystenterostomy, the common bile duct being cut and ligated, the animals would live. What was there in the length of the intestinal loop which saved the dog? What relation if any did the bile bear to the fatal outcome? Did a longer loop admit of certain detoxicating changes to take place? Was it perhaps true, as Mr. Moynihan had suggested, that the bile in itself was not the lethal agent? The studies of the essayist had opened up the question of metabolic changes in the alimentary canal to which attention had not previously been directed.

Dr. Arthur Bevan of Chicago advised the early exploration of the gland under gas anesthesia.

Dr. Rodman of Philadelphia said it was clear how difficult it was to differentiate the various lesions of the stomach even after laparotomy. Pylorectomy was often indicated but there was an element of danger in removing the gall-bladder because it afforded the only known channel for biliary drainage.

The Report of a Case of Chronic Peritonitis with Complete Obstruction Caused by Numerous Transverse Constrictions of a Previously Undescribed Character Throughout the Intestine.—Dr. M. F. Porter of Ft. Wayne, Ind., presented this case. He said that the intestine was found at operation to be covered by an organized false membrane which did not constrict the bowel, but which shortened it 80 per cent. The lumen was obstructed by infolding of all the coats. The etiology was in doubt, possibly the condition was the result of typhoid fever. No similar case had been recorded.

Dr. William H. Welch of Baltimore discussed the pathological findings of this rare case in detail and demonstrated the gross specimen.

Thursday, June 4—Third Day.

Artificial Respiration in Its Physiological Aspects.—Dr. Edward A. Schäfer of Edinburgh, Scotland, read this paper. He said that Benjamin Howard of New York, in 1868, was the first to publish any important statements on artificial respiration. Even at that early date it was pointed out that the reestablishment of the function depended upon the elasticity of the chest walls, and that this was particularly true in the resuscitation of the drowned. The position recommended at that time was practically the same as had been in vogue ever since, viz., with the patient supine and with the tongue dragged forward. Sylvester, who came later, had materially aided the subject, and frequently combinations were used of the two methods. The objection to them, however, was manifest, the principal one being that the patients were not prone, and, therefore, were not in suitable position to get the water out of the lungs. He was Chairman of the Royal Commission appointed to investigate the subject, and as a result of the many experiments studied by this Commission, with special spirometers and other forms of appliances, a very definite conclusion had been reached. It was this: That all patients upon whom attempts were to be made to produce artificial respiration should invariably be placed upon the belly. Pressure should then be made upon the loins and upon the lower ribs, the operator squatting or kneeling beside the patient. The operator's hands should be placed over the region referred to, the arms held rigid, and all the pressure derived from the forward and backward swaying of the body of the operator. For an adult, about sixty pounds pressure ought to be employed. The essayist presented a chart which showed the results of comparative experiments with all the known methods now in vogue, and showed that all except the prone pressure system caused a respiratory interchange that was insufficient. With the prone pressure method, an interchange amounting to several hundred cubic centimeters more than the normal interchange could easily be effected. This was a very far-reaching and important conclusion, and after it was brought to the attention of the authorities, steps were immediately taken to demonstrate the method before the accredited agents and instructors of the Royal Life Savings Service, and the prone pressure method was now in use throughout the United Kingdom for all cases of drowning.

Surgery of the Thoracic Cavity; Sauerbruch's Method of Preventing Pneumothorax.—Dr. F. Sauerbruch of Marburg, Germany, read this paper. He said that in his first experiments he had made use of positive pressure, but early in the work had come to the conclusion that negative pressure had many points to commend it. A very small amount of anesthetic was necessary, and no disturbance of any kind followed the opening of the chest wall. This was important in itself for delicate surgical work, even though it had been noted by many that in man at least, and certainly in an adult, one side of the chest could be opened without mortal danger. It was of great advantage in lung surgery to have the lung in normal motion, as it prevented suction of foreign matter into distant parts of the lung at the time of operation, and allowed of a coaptation of the lung to the side of the chest after operation without difficulty. He said that in cases of bronchiectasis, if not multiple, there was hope of cure by operation in the cabinet. He spoke of the rarity of carcinoma of the lung, and reported one case. As to the surgery of the thoracic esophagus, he said that he believed it had a brilliant future. His experiments showed that it was necessary to utilize some form of mechanical contrivance to coapt the surfaces, because, no matter how applied, stitches would leak. He said that a great many surgeons considered there was but little use for any form of apparatus designed to further the work upon the chest cavity, partly because the occasions for it were not frequent, and partly because one side of the chest had frequently been opened and reasonably good work done without any artificial pressure apparatus. He said, however, that unquestionably as the surgery of the part improved, and as more exploratory thoracotomies were done, the field would broaden with the increase of our knowledge of the subject. He demonstrated a very beautiful negative pressure cabinet, which was about 5 feet high by 5 wide by 6 long, which he had used for experimental purposes. The cabinet for operating upon the human beings was somewhat larger. This experimental cabinet was, however, a perfect model of the larger one, and of the large cabinet, twelve were now in successful operation in the German clinics.

Artificial Intrapulmonary Pressure; Application to Surgery of the Lungs.—Dr. Samuel Robinson read this paper. He said that there were obviously great objections to the use of a cabinet such as Professor Sauerbruch had

just described, and with which, as all who were at all conversant with the subject, knew he had done the most remarkable pioneer work. And for this work, the entire surgical community of the world should ever remain grateful, whether or not the positive or the negative pressure methods were eventually found to be the most practicable. From his own standpoint, the positive pressure had seemed to offer the greatest chances of the solution of the problem, and it had been in use in all the research work done at Harvard University. He had used the modification of the well-known method of Brauer, and was able to report that no fatalities could be attributed in their series to the use of the positive pressure. The fear of artificial emphysema, he thought, could now be justly considered groundless, because, after careful search for this lesion, none had been found. Indeed, it was of a difficult matter to produce it with a properly regulated overpressure apparatus, and nothing but the very grossest carelessness could produce this result. The various blood pressures had been studied, and they showed no variation if there was a properly adjusted air pressure. He considered the presence of an abundant air vent very essential in completing the flushing out of the alveoli of the lung. He showed a series of beautiful photographs, one of which showed the use of a pneumatic glass cone to cover the thoracic opening, and spoke of its application in case of removal of positive pressure apparatus.

Artificial Intrapulmonary Pressure; Application to Surgery of the Esophagus.—Dr. Nathan W. Green of New York read this paper. He briefly reviewed the literature of the subject, and referred to the classic work which had been done by Dr. Sauerbruch. He said that, so far as operations on the thorax were concerned, it was necessary only to apply a difference in pressure amounting to about 7 mm. of mercury. How this was applied seemed to the essayist of relatively little importance. It was hardly essential whether the pressure was a negative or a positive one. The practical point in the surgery of the chest was to find some easy method of obtaining the difference in pressure and of applying it. The work which he reported was done at the Surgical Research Laboratory of Columbia University, and all the experiments had been conducted with a positive pressure apparatus. He had not used any modification of the Brauer box, but had introduced the positive pressure, which, of course, was of an intermittent kind, directly into the lungs by an intralaryngeal tube. He said that unquestionably one of the most important factors favoring this method of applying the difference in pressure already referred to lay in the fact that, if for any reason the respiratory acts of the patient became lessened or ceased altogether, owing to any cause whatsoever, the patient could be resuscitated by the simple use of air unmixed with anesthetic. He spoke of the necessity of an uninterrupted pressure circle in coapting the serus surfaces of organs within the thorax, and stated that this was particularly true of any intrathoracic esophageal work. He agreed with Sauerbruch that stitches were of little avail in this sort of surgery, and that a mechanical device or appliance of some kind was necessary. Whether this increased difficulty in obtaining freedom from leakage after section of the thoracic alimentary canal depended upon the pumping motion of the diaphragm, or as was more probably the case, upon the negative pressure in the chest, or possibly upon inherent lack of cohesive power of the chest organs as compared with those in the abdominal cavity, these were subjects as yet to be worked out. He had done two types of operations upon the esophagus, viz., section and infolding of its termination with a transplantation of the end to another region of the cardia, which was brought up through an opening in the diaphragm, and a sidetracking operation, which left the normal orifice patent, and united the cardiac portion of the stomach to the esophagus above the opening. He said that particular care should be taken in securely fastening the stomach to the margins of the opening into the diaphragm, because failure to do this might result in a fatal prolapse of the abdominal viscera into the chest.

Dr. George Crile said that great credit was due Professor Schäfer in introducing this most rational and desirable method, and he believed that many lives, which would otherwise be lost by the older methods, would now be saved. He said that the effect of a small amount of air in resuscitating was wonderful. He said that, according to results obtained by studies in the Research Laboratory at Cleveland, excessive intrapulmonary pressure might give sudden death unless there had been an overtransfusion of blood prior to its application. This question of overtransfusion in cases of marked anemia was also being studied.

Dr. H. H. Janeway of New York said that he had experimented with both the negative and the positive pressure methods, and had found them equivalent in results. He spoke first of the extraordinary tendency to infection that existed within the chest, and, second, of the inadequacy of the suture method for intrathoracic work. He likened the intrathoracic conditions to an inverse Biers cupping device, and said that in his experience infection was almost certain to follow clean operative work in the chest, owing to this negative pressure. He had tested anastomoses made in the intestines with segments removed from the body and hung under hydrostatic pressure. He confirmed Dr. Sauerbruch's results as to the necessity of utilizing a button. He spoke of a modification which he had suggested might be applied to the Green intrathoracic button, which consisted, first, in covering the needle points by an elongated floating ring, and, second, by a broadening of the knives, so as to get immediate drainage. He showed photographs of the modification of the Brauer box, which he had used at the Surgical Research Laboratory of Columbia University, and drew attention to the electric lights in the box, which served the double purpose of lighting it and of warming the respired air. This he considered a very important point, because through its use, and also with the agency of an electric pad, which was applied to the outer surface of the body, a dog's temperature could be maintained throughout an intrathoracic operation of several hours' duration at a normal temperature of 101°.

Dr. Willy Meyer of New York spoke of the clinical side of the intrathoracic surgery. He said it was hard to discuss the subject, because it was still in its infancy, and only very crude work had been done clinically. There were very great technical difficulties in the development of this portion of the body, which was the last for the surgeon to invade. He thought that, although up to date the positive pressure method had been used by experimenters very largely in this country, there were great advantages in the negative chamber which Sauerbruch had devised.

Dr. Fell demonstrated that the familiar device which is associated with his name, and gave a history of a number of cases in which he had employed it continuously for artificial respiration extending over several days.

Dr. Smyth of New Orleans demonstrated the positive pressure appliance, which, in conjunction with Dr. Matas, he had elaborated at the Surgical Research Laboratory at Tulane University. He applied the overpressure through a laryngeal tube. There were two points of great importance in connection with this apparatus. The first, for which Dr. Smyth himself was personally responsible, and to which he had called attention several years ago, was the very ingenious application of a sliding valvular device attached to the cylinder of the pump. This rendered it possible to regulate the amount of air to be given from 1 to 800 cubic centimeters, and constituted the important, mechanical side of the apparatus. The second important point about this most admirable and convincing affair lay in its extreme portability. This was particularly marked

when contrasted with the more elaborate appliances which had been described by previous essayists. It could be packed in a very small valise, and the pump could be run by any one of ordinary intelligence. It was further arranged by a very simple device, so that either ether, chloroform, air, or oxygen might be employed alone or in conjunction.

Dr. J. B. Murphy of Chicago said that it was not the pneumothorax which did the harm, but the absence of respiratory exchange.

Dr. Martin Tinker of Ithaca said that for some years he had been in the habit of using a combination of the Sylvester and Howard methods of artificial respiration.

Dr. Sauerbruch, in closing, said that one advantage of the cabinet was that easy access was possible of the anesthetist to the patient. Further, that it should not be forgotten that healthy dogs had been used in the positive pressure work, and not sick human beings. That eleven dogs out of twelve, which had undergone esophageal resection, had recovered.

Dr. Robinson, in closing, said that he hoped in the next two years some simple form of apparatus would be devised which would further the surgery of the chest. He believed that some form of low-pressure apparatus would prove to be the thing of the future. Dr. Green, in closing, said that he agreed with Professor Schäfer that a small dose of atropine would be very valuable. The mediastinum was very movable in dogs and also in children. The rhythmical inflation of the lungs was a very necessary and valuable factor in his opinion favoring the intermittent positive pressure method.

The Surgical Importance of the Cervical Ribs.—Dr. John B. Roberts of Philadelphia said that the cervical ribs were probably very common, but that those which produced symptoms were relatively uncommon.

Dr. J. C. Stewart of Minneapolis said that an important factor in the recognition of cervical ribs lay in their tendency to elevate the scapula and slightly broaden the base of the neck. Every case of brachial neuralgia ought therefore to be subjected to the *x*-ray.

Dr. Brophy of Chicago demonstrated a number of patients upon whom he had operated for the cure of cleft palate.

Report of the Anesthesia Commission.—Dr. J. G. Mumford of Boston read this in abstract. He referred to the work which was in progress and the methods which the commission was employing in classifying its studies. Up to date, the general conclusion was that for the average practitioner, ether was the anesthetic of choice, although special methods, such as local anesthesia, rectal and spinal anesthesias, etc., certainly had a place in the hands of the skilled man. Nitrous oxide in major work probably had a very bright outlook.

Effects of Normal and Abnormal Variations of Peristalsis on Peritoneal Absorption.—Dr. J. L. Yates of Milwaukee read this paper. It was a final interpretation of studies which had been in progress during his association with Dr. Ochsner. The work had been done on dogs and had been conducted by the use of intraperitoneal injections of lampblack and solutions of snake venoms and normal salt solution. Postural studies had been made. The conclusions were that diffusion depends on physiological and physical phenomena and is restricted by maintenance of physiological inactivity. Morphine may limit it very markedly, soluble irritants are apparently effective, as is lampblack. Solutions spread more rapidly than suspensions.

Intestinal Anastomosis, Presentation of a New and Aseptic Method.—Dr. F. B. Walker of Detroit read this paper. He spoke of the need of cleanliness and demonstrated by preparations the new method. This consisted in tying the gut off, in resecting the part to be removed by the actual cautery, in placing Lembert's, and by the removal of the primary ligature which had been tied in a bowknot.

Gas Cysts of the Intestine.—Dr. J. M. T. Finney of Baltimore read this paper. He said that these cysts were first noted about 1825 in the intestines of a pig. About fourteen cases had been reported since 1876 in human beings. The cysts varied in size from the microscopic form to those about the size of a walnut. The condition was nearly always found when there had been associated circulatory trouble or intestinal obstruction. Careful analyses had been made of the contents of the sacs, but owing to the law of diffusion of gases, these were probably not very authentic. The most rational explanation was that they were a definite form of tumor, the cells of which possessed the ability to create gas. They were noninflammatory and for this reason were scarcely to be attributed to the ordinary action of bacteria. It was noted that the relief of the primary condition often cured the associated gas cysts.

Acute Diverticulitis of the Sigmoid.—Dr. George E. Brewer of New York read this paper. He made reference to an article which he read a year ago on left-sided suppuration. In this paper, he reported six cases of left-sided abdominal infection. Reference was made to a few instances in which these conditions had been found at autopsy, but in no case prior to the author's had the trouble been diagnosed antemortem. This in itself was sufficient proof that the condition was a very rare one. That its fatal outcome was rare was undoubtedly true, but it was rather undoubted that there were a great many cases of diverticulitis which passed for ordinary colic and which recovered in the ordinary course of treatment. He cited the history of a case operated upon by his associate, Dr. Flint, in which it was possible to diagnose the condition before operating. The diagnosis was greatly assisted by the fact that the patient was an intelligent man who had undergone an operation for a similar condition the year before. It was found impossible at the second operation to remove the diverticulum on account of the breadth of its base and the presence of many adhesions. It was therefore segregated peritoneally. The results were admirable.

Extirpation of the Rectum and Sigmoid for Cancer.—Dr. James P. Tuttle of New York read this paper. The careful study of a long series of cases of this nature was in the opinion of the author the only just means of reaching a definite conclusion. He had excluded all cases which had tended to make the report more favorable and felt that the percentages as given were very close to the truth as represented by the present study of the development of the technique. Everything depended on technique and judgment. Age was unfavorable for immediate results but most favorable for common recurrences. The site of the disease was most important. He did all his work through the perineal route, now having come to the conclusion that for small-handed people this was preferable to any other. He regarded the use of the Fowler position as confirmed. Pain was rare unless the margin and the skin was involved. Constipation was likely to be the cause rather than the effect of the carcinoma. Twenty per cent. of his cases were incontinent.

Dr. E. W. Andrews said the results in Dr. Yates' cases were conclusive. We were on the right track surgically when we invoked the aid of gravity in abdominal drainage.

Dr. A. J. Ochsner said that although twenty years of important clinical observations had been made, these must all be corroborated by animal experimentation. He considered Dr. Yates' contribution as exceedingly important and as corroborating his own clinical theories. As to the importance of Dr. Walker's technique, he said that patients died of conditions which were more often preoperative than those which resulted from soiling at time of operation.

Dr. Gregory Connell said that the necessity still existed for important technique in abdominal work. He thought that through-and-through stitches were necessary for strength, although the nominal absence of peristalsis

following for six hours after operation afforded ample time for sero serus union to take place.

Dr. Ransohoff of Cincinnati said that hemorrhage constituted the greatest danger in abdominal gunshot wounds.

Dr. Wathen of Louisville, in discussing Dr. Finney's case, said that it was certainly a pathological curiosity. These gas collections were usually associated with a palpable tumor.

Dr. Finney said that Dr. Welch would not commit himself as to the character of the tumor. An interesting point about it was its very wide dissemination.

Dr. Eisendrath said that we were indebted to Dr. Brewer for first calling the attention of the surgical community to these cases of diverticulitis. The chronic form was the common one and all were frequently associated with stenotic conditions.

Dr. Truesdale of Fall River, Mass., said that a vaccine virus from the colon bacillus had been used very satisfactorily to combat severe peritoneal infections due to this germ.

Dr. McArthur of Chicago said that he felt much encouraged by Dr. Tuttle's paper.

Dr. Evans of Dayton said that after hearing Dr. Tuttle's paper he believed that every case, even if apparently hopeless, should be operated upon. He advised the transplantation of the levator muscles.

SECTION ON PRACTICE OF MEDICINE.

Wednesday June 3—Second Day.

Dr. C. F. Hoover of Cleveland in the Chair.

High Arterial Tension of Nervous Origin; Diagnosis, Consequences, and Treatment.—Dr. Louis Faugères Bishop of New York read this paper. He said this form of high arterial tension resulted uniformly in an elevation of the blood pressure through increased output of heart energy. The origin of the hypertonia of the arteries was found in an increase in the natural tone of the involuntary muscles in the median coat of the blood-vessels. The condition was diagnosed by the high reading of the sphygmomanometer and the exclusion of sufficient causes outside of the brain. The recognition of hypertonia vasorum as the origin of these cases led to hopeful and successful therapeutics. Drawings were shown of hypertonia vasorum in arteries in which the various lesions were diagrammatically represented. The importance of a quick method of determining blood pressure so that all cases could be examined just as the pulse was felt, had led him to devise a hydrostatic instrument whereby he could quickly apply water pressure to the brachial artery to ascertain the pressure required to stop the pulse wave. This was what he termed a blood pressure detector. This instrument had already been described in the Medical Record. The treatment consisted in the hygienic modification of the pathological physiology and he suggested the principles upon which it might be successfully carried out. Every case should be treated upon its merits, and it was of the utmost importance that the physician should be in complete command and not only be an occasional advisor. The points he wished to emphasize were the immense clinical importance to the physiological element in cardiovascular disease, and its susceptibility of early recognition and successful treatment.

The Factors in the Estimation of Blood Pressure.—Dr. Joseph Eichberg of Cincinnati said that the first factor in the interpretation of blood pressure must be a satisfactory instrument; it should be of service for general work, be portable, quick of adjustment, and accurate, and these qualities were possessed in eminent degree by the tonometer of Recklinghausen. It did not detract from the achievement of Riva-Rocci that later modification had improved the technique. A notable advance in the Recklinghausen apparatus was found in the pump, and its ability to measure both systolic and diastolic pressures. The Erlanger instrument was suitable only for hospital or office use. The tonometer of Recklinghausen was the only instrument thus far devised that conveniently gave both data with certainty and promptness. The quantity and viscosity of the blood necessarily influenced the blood pressure. The most important factor in the control of the blood pressure was the nervous system. Passive movements, except those causing pressure on the thorax or abdomen might be performed for a long time without increase of pressure. Dyspnea increased the blood pressure very materially, not only in the acute suffocative conditions, but dyspnea of long standing. Contrary to what might be expected, acute infectious diseases had but little influence on the blood pressure. There had been found in typhoid fever cases a hypertension increasing with complications, parallel to the severity of the disease and to deepening intoxication. It should be remembered that hypertension, however, was not a disease. The general assumption had been that hypertension was in itself very dangerous, inasmuch as it led to alteration of the vessel wall, possibly to rupture, or induced cardiac hypertrophy and subsequent dilatation, so that in every case they should resort to baths, iodine compounds, and nitrites. This view was strongly combated by some. Many agents reduced the blood pressure. Warm, effervescent baths were of signal value. The functional capacity of the heart was increased by combining the baths with exercise. The effect of iodine in arteriosclerosis was perhaps to be explained by the control which it exercised over the polycythemia, and by reducing the viscosity of the blood, rather than to any influence on the anatomical change. It was, however, in the direction of prevention that they should most earnestly apply their efforts. He said the following conclusions seemed justified: (1) The routine interrogation of the blood pressure should constitute part of the regular examination of each case. (2) Both systolic and diastolic pressures were necessarily in the solution of the problem. (3) Systolic values of more than 130 mm. called for further study. (4) The most important feature of the study of blood pressure was found in its behavior under tests with measured amount of work. (5) Increase of blood pressure was often conservative, and then called for no interference. (6) A pressure that was at all times above normal might be the only, as it often was, the earliest, evidence of arterial sclerosis.

Dr. W. Forest Dutton of Pittsburg said that the study of hypertonic contraction and blood pressure was practically in its infancy, but they had certainly learned a few important facts from their investigations and observations. The etiology of hypertonic contraction readily resolved itself into two great factors or divisions, the influence of the nervous system, and the composition of the blood. He said he was not referring to the mechanical conception which would make the arteries mere elastic tubes, but he was referring to living tissue. He had been recently experimenting with methylene blue, administering it in large doses with marked retention of the drug in the tissues. This manifested itself by a diminished excretion, etc. Owing to disturbances of the renal function, a retention of the drug took place in the tissues. After a saturation of the tissues, every additional dose caused lessened functional activity, and this effect was most apparent in the arteries, causing at once an hypertonic contraction and hyperemia of the renal capillaries, as well as other pathological changes.

Dr. N. S. Davis of Chicago said he was particularly interested in the chart presented by Dr. Bishop because it brought out so distinctly the fact that a highly deseased arterial wall still retained its power of contraction, a fact that at the bedside physicians frequently overlooked. A general thickness with rigidity of the arterial wall was generally ascribed to disease in the arterial wall and not always correctly. Furthermore, many times a diseased wall

had a greater degree of tonicity, or was more easily stimulated to contraction than a healthy arterial wall. Another point referred to the size of the lumen of the artery; when one compressed the artery, to measure the degree to which you had compressed it, one not alone measured the compressibility of the artery's walls, but the pressure of the blood within the artery as well. These were factors that should be borne in mind.

Dr. Arthur D. Hirschfelder of Baltimore said the members of the section were greatly indebted to Dr. Bishop for demonstrating to them his instrument, a very ingenious and simple method for determining the maximum pressure. An apparatus that was portable was much to be desired. The instrument presented by Dr. Eichberg, that of Recklinghausen, was also a useful piece of apparatus but was only a little more pretentious in so far as it attempted to replace the apparatus of Erlanger which had been proven to be an accurate instrument by experimental control on animals. But like all other forms of apparatus which depended upon the spring of steel, it had to be frequently tested because there was only a certain life to its accuracy. It must be reexamined at the shops frequently, or sent back to Germany. Unless these tests were continually made, one could not be quite sure of the proper resistance of the spring. One of the great advantages of the Erlanger apparatus was in testing the variations in the pulse pressure (called by the Germans amplitude); this became a matter of great importance to be able to determine more or less infallibly the point of diastolic pressure; in this the Erlanger apparatus had a distinct advantage.

Dr. I. J. Wolf of Kansas City said he was much interested in what Dr. Eichberg said with regard to the mental influence on the rise and fall of blood pressure. The same phenomenon had been seen by Pawlow in diseases of the stomach; the influence of the mind on the gastric secretions was as great as the influence of food itself. This mental influence upon the rise and fall in the blood pressure was as great as the influence of work. Increase in the blood pressure was often a compensatory act, and then it was dangerous to interfere. For instance, there were cases of Bright's disease, or even arteriosclerosis with an hypertrophied heart; he had noticed a number of such cases that came under his observation with a failing heart and in which men called in consultation advised reducing the blood pressure with nitrites; when used these patients became much worse. It was only by using digitalis that improvement resulted. In these cases of failing heart it was not a question, in his opinion, of whether the blood pressure was 240 or 250; it was a question of what was the blood pressure before he was seen by the doctor.

Dr. Joseph L. Miller of Chicago said he wished to reinforce the statements made that cases of hypertension did not necessarily require treatment. He thought that all would agree that the most frequent cause of hypertension was a nephritis. Arteriosclerosis of the splanchnic vessels was also a cause. The question arose whether lowering the blood pressure in such cases would reduce the elimination from the kidney. There had been a great deal of work done upon this subject, the effect of drugs which lowered blood pressure, and the effect upon the elimination from the kidneys.

Dr. Wright of Akron, Ohio, called attention to the various kinds of pressure, that from business competition, social functions, etc. The modern house to-day had thermometers, barometers, adenometers, clinical thermometers, in fact, a small laboratory for use before the doctor was sent for. He compared the old-fashioned doctor with the doctor of to-day, as well as the farmer of one hundred years ago with the man of to-day. What he wanted, he said, was the old-fashioned doctor who, merely with his finger tips, gained some idea of the blood pressure. But it should be remembered that the old farmer of one hundred years ago was a hard-working man, who had muscles of iron and a constitution of steel, who got his eight hours' sleep, and who read only his weekly newspaper; that condition, however, was a different proposition from what it was to-day. All these things should be considered.

Dr. C. F. Hoover of Cleveland said that there were some cases of Bright's disease in which any attempt made to lower the arterial tension would cause a profound depression; the patients became weaker after the employment of the nitrites. He had seen a number of cases of chronic interstitial nephritis in which the elimination of urine in twenty-four hours was very small; these patients were given diuretin and caffeine without diuresis. Then lowering the tension would be followed by a profuse diuresis. He referred to an experience he had had in which caffeine and diuretin were used without effect until trinitrin was administered, thus lowering the arterial tension. He believed that Dr. Wright's point was good, but the doctor who could learn much of the blood pressure with his finger alone was not yet made.

Some Comments on the Physics of Physical Signs, with Special Reference to the Respiratory Murmur.—Dr. H. D. Arnold of Boston read this paper. He said that those were mistaken who assumed that medicine had already attained the rank of a science, for only a few steps had as yet been made in that direction. Unfortunately our knowledge of physical signs had lagged far behind many other branches of medical knowledge; it was far from deserving the term "scientific," and it had fallen into disrepute which was more or less deserved. One reason for the disrepute of physical signs was that physicians did not train their senses enough to keenness of perception. Again, they failed to fully appreciate that those signs were based on the laws of physics, and they were too often oblivious to the distinction between fact and fancy in their explanations. Recent textbooks on Physical Diagnosis were making some efforts in the right direction, but they were still open to severe criticism because they failed to discriminate between unfounded theories and established facts or well-grounded hypotheses. In order to illustrate these faulty methods he chose the respiratory murmur for consideration, although there were other topics which would make equally good examples.

Dr. Jack of Buffalo, Dr. Sewell of Denver, Dr. Scott of Iowa, Dr. Edwards of California, discussed the paper.

The Clinical Value of the Quantitative Estimation of Pepsin, with Special Reference to the Mette and Ricin Methods.—Drs. Clifford B. Farr and Edward H. Goodman of Philadelphia presented this communication, which was read by Dr. Goodman. In carcinoma ventriculi, achylia, and occasionally in chronic gastritis, the pepsin determination revealed values below the minimal normal, but as a rule in neuroses and chronic gastritis the pepsin was relatively but little affected in contradistinction to carcinoma and achylia, and this would seem to be of assistance in making a differential diagnosis between these conditions. They had found, as had others, that within normal limits there were wide variations without apparent relation to the acidity, but at present they were not in a position to draw and diagnostic or therapeutic conclusions from these observations. The results obtained with the ricin method corresponded with those shown by the Mette method, *i.e.* normal values and subnormal values more clearly shown, but the finer variations were not seen and when present did not correspond with the Mette results. This was true even when they had made allowance for differences in the Mette tubes by means of the controls referred to by them. Both tests were valuable as rough quantitative methods, and were carried out with equal facility. The Mette had the advantage of excluding variations due to differences in acidity without requiring any previous tritration. There had been no attempt to see whether the ricin method followed the law of Schütz, nor had there been any attempt made to bring the various tubes to a uniform acidity. The variation in the acidity of the five tubes seemed *a priori* to be fruitful of grave errors. This could probably have been

obviated by suitable dilutions with HCl, similar to those employed by Nirenstein and Schiff in their modification of the Mette method. These questions might form the basis of a supplementary communication. They had made very little therapeutic use of their knowledge. The wide variations in the pepsin values would suggest that the drug had been too much despised by stomach specialists, although this could not be said of practitioners in general. It would seem to them to be indicated in cases showing subnormal peptic values, with preservation of at least a fair degree of acidity. In chronic gastritis with low acidity and low pepsin, in achylia, and in carcinoma, it would be necessary to add HCl. In many cases it was doubtful if enough acid could be introduced except occasionally with a stomach tube, to allow of normal proteolysis. A practical expedient (Sailer) was to saturate meat or milk, before taking, with dilute HCl until free acid could be detected, after which a small dose of HCl would suffice. Pepsin should be given in sufficient amounts to make a 1-4 to 1-16 per cent. solution in the contents of the stomach—estimated in advance. It should be given with or followed by at least twenty minims of dilute HCl. Both might be repeated once or twice at short intervals to make up for the amount expelled into the duodenum. The normal gastric secretion of the dog, obtained through a Pawlow fistula, had been advocated by Frémont and others in doses of 100 to 500 c.c.

Dr. John H. Musser of Philadelphia, Dr. M. J. Lichty of Cleveland, Dr. Williams of New York, and Dr. Nathan Rosewater of Cleveland discussed this paper.

The Importance of Recent Studies Upon the Circulation for the Practice of Medicine.—Dr. Arthur D. Hirschfelder of Baltimore read this paper. He said that one of the most interesting and important results of physiological study had been the physiological analysis of the irregular pulses, which had led them to divide them into four groups. First, those which, either associated with certain phases of respiration or with meningitis, or in children, neurasthenics, convalescents from febrile diseases, were of neurogenic origin. These were not associated with any cardiac disturbances, disappeared temporarily under atropin, and sometimes disappeared under general tonic treatment, hygienic measures, and strychnine. Second, those due to diminished contractility, shown in the pulsus alterans, and in which, though the rate was regular, each alternate beat was small. This was most common in very rapid pulses and also in some cases of angina pectoris. It always showed that the heart was beating too fast and that its strength was insufficient. Third, they had to deal with the three varieties of heart block at the various sites along that inverted Y-shaped path of Purkinje fibers. Fourth, they had a group of irregularities due to the abnormal impulses, extrasystoles, which might arise either in the auricles, the ventricles, or the His bundle. Ventricular extrasystoles were often brought about by inability of the heart to empty itself. Regularity was then restored by digitalis. At other times there was too great irregularity, and digitalis would only serve to increase the arrhythmia. In paroxysmal tachycardia they also had to deal with a peculiar sudden change of rate, almost doubling and almost halving, sometimes associated with irregularity in the transitional stages but usually perfectly regular. Dr. Hirschfelder then considered the velocity of the blood flow in disease.

Dr. W. S. Thayer of Baltimore and Dr. G. W. McCaskey of Fort Wayne discussed the paper.

The Viscosity of the Blood and Its Clinical Significance.—Dr. G. W. McCaskey of Fort Wayne, Ind., read this paper and offered the following conclusions: (1) The determination of the viscosity of the blood was of distinct clinical value if made practicable for routine clinical use. (2) Approximate determinations were entirely sufficient for the purpose of clinical medicine, as there were considerable physiological variations in the same individual, depending upon the time of day, exercise, digestion, diet, etc. (3) Individual diseases did not change viscosity in any characteristic way except as they incidentally influenced the blood. (4) These changes depended largely on the number and character of the corpuscles, but also on the proteid content of the serum and on certain abstruse and unknown changes, such as those produced by the intravenous injection of the distilled water which curiously enough raised viscosity while normal saline solutions lowered it. (5) The determination should be made promptly before the corpuscles had time to settle. (6) Alcohol immediately raised viscosity whether introduced intravenously or through stomach or duodenum. (7) Accumulation of carbon dioxide in blood either by local or general asphyxia tremendously increased viscosity and burdened the heart. (8) This was immediately relieved to a certain extent by the inhalation of oxygen. (9) Venesection immediately lowered viscosity and the effect was very lasting. (10) Viscosity was influenced by diet and especially increased by the quantity of meat, which was possibly due simply to the increase of proteid, but might be the result of toxic constituents. (11) Viscosity was usually low in clinical Bright's disease, which was due to hydrema, but it was easily possible that there might be a preliminary stage of high viscosity before the clinical features of Bright's disease were produced. (12) The viscosity rose in a general way with the specific gravity of the blood, but there were numerous exceptions, such, for instance, as the high viscosities of fevers with low specific gravity.

Dr. S. P. Black of Pasadena, Cal., Dr. Henry B. Hemenway of Evanston, Ill., Dr. Goodman of Chicago, Dr. Nathan Rosewater of Cleveland, Dr. F. J. Hultgen of Chicago, and Dr. L. F. Bishop of New York discussed this paper.

SECTION ON OBSTETRICS AND DISEASES OF WOMEN.

Tuesday, June 2—First Day.

Dr. Walter B. Dorsett of St. Louis, Chairman.

Chairman's Address: Criminal Abortion in Its Broadest Sense.—Dr. W. B. Dorsett said the subject of his address should concern us, not only as obstetricians and gynecologists, but as citizens of a great republic. In law, no case could be prosecuted unless sufficient evidence was obtained from those who are in possession of it. That the surgeon is in possession of such evidence was known, for he sees every day the dire results of the work of midwives and abortionists. It was useless to expect ecclesiastical intervention. Many young married couples, for financial or social reasons, agreed not to become parents for two or three years after marriage—an agreement that necessitated either efforts to prevent conception, or the induction of abortion. Many of these young women, unfortunately, were relieved of their burden by the fashionable doctor, who readily induced abortion for them, because they were the victims of hyperemesis gravidarum, or because of suppression of menses, or because their urine was loaded with albumin! Any one of these conditions, of course, necessitated immediate abortion. The secular press, with its advertisements of abortifacients, would be slow to respond to a call to aid in the exterminating of the abortionists. Much had been said about the alarming increase of race suicide, but little had been done toward enforcing the laws now on our statute books. It had been estimated that in New York, 100,000 abortions were performed annually, while in Chicago, Dr. C. S. Bacon, in a paper read recently before the Chicago Medical Society, estimated the annual number at from 6,000 to 10,000. From 20 to 25 per cent. of all pregnancies terminated in abortion, and of these, fully half were criminal. The speaker offered some suggestions which he thought, if carried out, would go far toward ridding us of this evil. (1) Medical jurisprudence and medical ethics should be

made compulsory studies in our medical schools. (2) Inefficient laws should be properly amended, or good and efficient laws enacted.

Dr. Martin of Louisville said that in a moral, or in a pathological sense, no subject was of greater importance. From the pathological side it was easily appreciated by surgeons, who saw every day the results of the abortionist. From its moral side, it was repulsive to every honest doctor and citizen. It should not be considered a crime on the part of the woman any more than on the part of the man who performed the operation upon her.

Dr. Carstens of Detroit thought that this was a very difficult subject to deal with. There were laws against murder, still people committed murder; and there were laws against abortion, still people induced abortions. He thought that an important cause was the rapid rise from a lower stratum of society to a higher. Such people had not grown as rapidly morally as they had financially.

Dr. Helen C. Putnam of Providence had worked in the public schools, and had investigated to see what was being done in the matter of education in the physiology and hygiene of sex. Many teachers had expressed anxiety on this point, and a few, trained in biology, were capable teachers of this subject. The children varied in age from eight to fourteen. They were first taught the origin of life in plants and in the elementary animals. Later they were given a frank sex talk, in which the sexual relations of plants and animals were compared with those of the human family. Thus the children arrived at the subject naturally, without shock or surprise. This method, the speaker thought, was more efficient than laws.

Dr. R. W. Holmes of Chicago said that he had presided for three years over a committee on abortion in the Chicago Medical Society. He thought that the public did not want an attack made on abortion, and was convinced that what we needed was not more laws, but the enforcement of those that we already have. A female detective in Chicago visited 223 midwives, 22 per cent. of whom openly agreed to induce an abortion. The percentage was brought up to 33 per cent. by others who were manifestly willing to induce one, but who would not say so openly.

Dr. Abrams of Michigan had spent two years in the legislature of his State. Among innumerable bills which came before the committee on legislation, there was one in which the question was raised whether or not a woman upon whom an abortion had been performed should be considered a criminal. He was shortly called before the judiciary committee and asked whether he favored abortion. The lawyers of his acquaintance all assured him that to make the woman a criminal party would be to destroy all chance of obtaining evidence.

Dr. Henry of Omaha thought that back of the enactment of laws there must be education in the schools and colleges on two subjects—the physical evil of abortion and the moral evil of abortion. For instruction in the latter we should depend to some extent on the clergy, who should be taught that life is present before quickening is felt.

Dr. Denslow Lewis of Chicago endorsed what the last speaker had said on the subject of education. The education of the young in sex relations and in venereal diseases and their consequences was one sovereign duty. The girl must know that conception is apt to follow the sexual act. He felt sure that many girls of from twelve to fourteen years of age submitted to the sexual act without the least idea of the consequences.

Dr. August Martin of Berlin said that all agreed in condemning abortion. It was forbidden by law and by the professional code, but no laws had yet been successful in eliminating it. The German law made trouble by forbidding the doctor who treated the case subsequently to speak on the subject in court unless one of the parties interested gave consent. But unfortunately one of them frequently was no more. Many faults and errors in our profession had gradually disappeared since medical meetings had come to be so widely held and attended, and thus he believed that the frequent discussion of this matter in medical meetings would finally be productive of good.

Dr. Yarrow of Chicago said that the enactment of laws was comparatively easy, but their enforcement was difficult. We could not enforce a law with which the public was not in sympathy. Among the married poor there was very little danger of race suicide—it was the high-born American that must be instructed.

Dr. F. F. Lawrence of Columbus thought that we should never lose sight of the fact that moral problems could not be solved by statutory enactment. The public should be educated to know that a conception meant a human life, and its murder was as much murder as was the killing of the child after delivery. He offered a resolution urging the House of Delegates to attempt the education of the youth of the country by considering the publication of a lay journal.

Dr. C. C. Frederick of Buffalo offered the following resolution: "Resolved, that the address of the chair be referred to a committee, for the consideration of laws now in force, or the possible enactment of new ones. The committee will confer with State committees and with the attorneys general of the various States." Carried.

Abdominal Cervical Cesarean Section.—Dr. J. Pfannenstiel of Kiel, Germany, thought that our results had been better since we had learned to submit to cesarean section only such women as had probably not been infected by frequent examinations, prolonged labor, or attempts at instrumental delivery. In cases where infection had probably occurred, it had been suggested that they be delivered through an incision which did not open into the peritoneal cavity. But these methods were none of them a certain safeguard against infection of the peritoneum. Neither were the attempts to prevent infection of the peritoneum, by an already infected liquor amnii, in the course of the ordinary cesarean section. The author had been trying lately the introduction into the peritoneal cavity during the ordinary section of about 200 c.c. of sterile olive oil. His experience had not been wide enough, so far, to enable him to indorse it. Experiments on guinea pigs, however, had shown the procedure to be free of danger. He would not hesitate to operate on a mildly febrile case transperitoneally, with the use of oil. A technical description of the author's extraperitoneal operation then followed. The advantages claimed for it were that the mortality was diminished, the danger of ventral hernia excluded, and the patients were able to get up on the third day.

Cesarean Section, with Report of Two Cases.—Dr. J. M. Trigg of Shawnee, Okla., read this paper. He showed by statistics that the later in labor the operation was performed the greater was the mortality. He urged early operation on this account. A list of indications for operation, with a detailed description of the technique followed.

Abdominal Cesarean Section as Performed at the New York Lying-in Hospital.—Dr. Ross McPherson of New York read this paper. The indications for operation were given, with an accurate description of the technique employed by Dr. Asa B. Davis. The important points in this technique were, that the incision was made high up in the uterine wall, the uterus was not lifted out of the peritoneal cavity, and no compression was attempted for the control of the hemorrhage. Thirty mothers were lost, but when one subtracted the cases that died of postpartum eclampsia, paraplegia, carcinoma, and other causes, unconnected with the operation, the mortality was only 4.8 per cent. Nine who died of septic peritonitis were all proven by cultures to have had streptococci in the vagina before the operation was begun. These were all cases that had been treated outside before admission to the hospital. There were fourteen still births in the series.

Dr. Martin of Louisville thought that craniotomy on

the living child was no longer necessary. It was more difficult, and destroyed the life of every child and nearly every mother, whereas cesarean section saved nearly every mother and child. He expressed himself as in favor of cesarean section in nearly every case of placenta prævia.

Dr. J. B. De Lee of Chicago thought that there was more danger of peritonitis in abdominal operations on the pregnant woman than in the nonpregnant. To improve our results we must improve the conditions under which the operation is done. If we improved our obstetrics in general also we would save ten times as many children as would be saved by an improvement in operative measures.

Dr. H. D. Fry of Washington did not like the idea of a low incision, because the higher we went in the uterus the smaller the vessels became. He did not want to get his patients up on the third day. In reply to Dr. McPherson, he though vaginal cesarean section more suitable in eclampsia than the abdominal. He disagreed with Dr. Martin as to placenta prævia being an indication for section. He had delivered many successfully by the natural passage.

Dr. Watkins of Chicago thought that hemorrhage in these abdominal operations was due more to interference with the blood supply of the uterine muscles on the part of the clamp, and to a consequent impairment of their contractility than to any other cause. Also, he thought that any undue manipulation of the uterus tended to crowd the clots out of the sinuses. For this reason he did not advocate the removal of the uterus from the abdominal cavity.

Dr. Carstens of Detroit thought the Pfannenstiel operation excellent in a hospital, where the surroundings could be controlled, but only in such a place. He thought there was grave danger of infection through the lymph channels which were opened up in the cellular tissue. Vaginal cesarean section he considered to be the one single operation in eclampsia, for a child can be delivered by this method in three minutes.

Dr. Greene of Rome, N. Y., did not believe that the minor points made any difference. The one great thing was to be sure of the diagnosis and then to operate quickly. "Get in and then get out."

Dr. Frankenthal of Chicago said that he would hesitate to subject any of his patients to the extraperitoneal operation, for he believed that the peritoneum was very easily torn through.

Dr. I. S. Stone of Washington was opposed to the Pfannenstiel operation. He would rather trust the peritoneum to take care of a slight infection than to tear and crush the cellular tissue about the bladder.

Three Procedures for Entering the Abdominal Cavity.—Dr. E. E. Montgomery of Philadelphia thought that the vaginal route was the best in retrouterine collections, for explorations, for the treatment of diseases of the tubes and ovaries, for the discovery of a ruptured tubal pregnancy, or for hysterectomy, especially in very fat subjects. Its advantages were that drainage was better and restoration to health surer, hernia and adhesions being absent. Its disadvantages were that one worked blindly, injuries to the intestine might be overlooked, and extensive adhesions might not be recognized. The abdominal route had the widest application, giving, as it did, ready access to abdomen and pelvis. But there was more discomfort during convalescence, and drainage was not so good. The Pfannenstiel operation was then described in detail. It was convenient in operations about the bladder, especially in fleshy women, the chances of hernia were less, and the scar was obscured by the pubic hair, but the operation had a limited application.

Dr. Herman J. Boldt of New York took exception to the statement that convalescence was more rapid after the Pfannenstiel operation. He had gradually limited more and more the field of utility for the vaginal route.

Dr. R. B. Hall of Cincinnati was in favor of the vaginal route in opening collections of pus that might get into the peritoneum if opened by way of the abdomen. He would limit the application of the vaginal route to the evacuation of acute collections of pus in the cul-de-sac.

Dr. Betz was in favor of the vaginal route only in acute cases for temporary relief.

SECTION ON DISEASES OF CHILDREN.

Tuesday, June 2—First Day.

Dr. Edwin E. Graham of Philadelphia in the Chair.

Chairman's Address: Infant Mortality.—Dr. Edwin E. Graham of Philadelphia delivered this address, which was based upon a statistical study of the subject, and the results were summarized as follows: (1) Gastrointestinal diseases were the principal causes of the high death rate among infants. (2) The greatest mortality occurred during the summer months. (3) The most dangerous period was from the first to the third month of infancy. (4) The mortality was greater among the children of the poor than those of the well to do. (5) Unhygienic surroundings were responsible for a considerable number of deaths among infants. (6) Many cases of infanticide were caused by neglect on the part of the mother. (7) Coroners' inquests were not rigid enough. (8) Race suicide was not a theory but a fact. (9) Alcoholism in the parents was an important etiological factor. (10) Insurance companies and burial clubs increased the death rate. (11) Congenital debility was responsible for about 50 per cent. of the deaths within four weeks after birth. (12) A plea for the encouragement of breast-feeding was urged. (13) Infants' hospitals and day nurseries were upheld.

The Character of the Stools in Diarrheal Affections of Infants, with Special Reference to the Conditions of the Intestine.—Dr. J. H. Mason Knox, Jr., of Baltimore presented this subject. He said that his results were founded upon observations noted at autopsy of 100 fatal cases of diarrheal affections in infants. The macroscopic character of the stools with reference to the presence of blood, pus, and mucus was compared with the lesions found post mortem in the intestinal tract. He epitomized his remarks as follows: (1) Of forty cases noted with mucus in the stools, one-half showed that the lesion was in the small intestine. (2) Presence of blood indicated roughening of intestinal mucosa. (3) Pus alone in the stools pointed to an ulceration of the intestinal mucosa, especially of the large intestine. (4) Blood and pus were more frequently found after second week of illness.

Dr. J. A. Work of Indiana said that he was anxious to know the cause of the diarrheal affections in children.

Dr. T. W. Kilmer of New York believed that some cases of diarrheal affection terminated fatally, and no intestinal lesion was found at autopsy.

Dr. Charles G. Kerley of New York said that membranous colitis in infants showed normal stools, and some cases had terminated fatally.

Dr. A. Jacobi of New York complimented the writer of the paper, and said he wanted to learn something of the etiology, prognosis, and treatment of such cases, and hoped for a subsequent paper on the subject.

Dr. Knox, in closing, said that the cases studied were routine ones, and the children were all under eighteen months of age. He thought the membranous type of colitis was rarely found.

Studies in Infantile Digestion.—Dr. Alfred Friedlander of Cincinnati read this paper, which treated of the adaptation of Einhorn's digestive head method of studying gastrointestinal digestion in infants and young children. He stated that observations were noted in the study of 150 cases. He explained the method carried out in the experiments. Small pieces of various foodstuffs—raw beef, potato, catgut, mutton-fat, sweetbread—were tied

to small glass beads with pieces of silk. The beads were of different colors, and the foodstuffs were placed in small bags of gauze and fastened to the beads. These were administered to the little patient and later recovered from the stools. The mutton-fat was intended to test the fat digestion; the beef, the proteid digestion; the catgut, the fibrin digestion; the potato, the starch digestion, and the sweetbread, the nuclein digestion. The results were favorable in a large number of cases tried, except in case of the starch digestion.

Dr. J. P. Sedgwick of Minnesota suggested that an emulsified fat be substituted for the mutton-fat.

Dr. Arthur W. Fairbanks of Boston said that Dr. Friedlander's paper proved the uselessness of the potato in the dietary of childhood.

Dr. J. G. Allen of Chicago said that the experiments reported ware quite practical and interesting.

Dr. Friedlander, in closing, said that the methods he reported were not conclusive. He thought the substitution of emulsified fat in place of mutton-fat was a good idea.

Rachitic Erosions of the Permanent Teeth Associated with Visual Defects.—Dr. I. A. Abt of Chicago presented this communication, with report of a case. The patient was a boy, age 12 years. The family history was negative. At the age of 2 months he was placed on artificial food. No teeth were erupted until the second year. During the first year he suffered from convulsions. His skull was large and he was mentally dull. Dimness of vision was complained of, and, an examination of the eyes revealed a double lamellar cataract. The presence of the cataracts was partly explained by the fact that during the convulsive attacks the eyes were subjected to severe twitching movements which disturbed the fibers of the lens. The erosions of the teeth were caused by rickets, and were probably one of the sequellæ of that disease.

Dr. R. B. Gilbert of Louisville said that the erosion of the teeth was due to an insufficiency of lime salts.

Dr. J. M. Dodson of Chicago said he had treated several patients with erosion of the teeth and that they recovered on administration of tonics.

Dr. H. M. McClanahan of Omaha believed that rickets had increased among children.

Dr. Martin Wood of Illinois cited a case of pneumonia which showed erosion of the teeth but no signs of rickets.

Curative Effects of Rest in Children with Persistent Loss of Appetite.—Dr. Irving M. Snow of Buffalo read this paper. He said that the child so afflicted was underweight, nervous, petulant, and quickly fatigued. He believed these symptoms were associated with cardiac dilatation and anemia, and were quite distinct from anorexia nervosa. He found that tonics and change of air were of no avail in the treatment. His method of treating such cases was rest in bed for two weeks. Afterward the child was allowed perfect freedom. The results were favorable.

Dr. Arthur W. Fairbanks of Boston believed in absolute rest in bed for a longer period than two weeks. He stated that warm saline baths, massage, and, later, resistance exercises were of use.

Dr. T. D. Park of Alabama believed in stimulating the heart muscle in anorexia with cardiac weakness.

Dr. Charles G. Kerley of New York thought such patients did better with change of air.

Dr. Clarendon Rutherford of Chicago cited a case of tuberculous hip-joint disease which was benefited by the rest in bed.

Dr. W. E. Taylor of Buffalo said he had a patient suffering from loss of appetite who was not benefited by rest in bed and showed no gain in weight.

Dr. Snow, in closing, said that rest and perfect freedom were of great value in the conditions named. Dr. Taylor's patient, he thought, was somewhat nervous and required no treatment.

(To be continued.)

MILK-FREE FLUID DIET, AND RECTAL IRRIGATIONS IN TYPHOID FEVER.

A FURTHER REPORT.*

By A. SEIBERT, M.D.,

NEW YORK.

PROF. OF PEDIATRICS, NEW YORK POLYCLINIC; VISITING PHYSICIAN TO ST. FRANCIS HOSPITAL.

At the stated meeting of the New York Academy of Medicine, on March 16, 1888, the author reported on an investigation concerning the influence of the weather on the causation of acute gastro-enteritis in young children (MEDICAL RECORD, March 24, 1888). The meteorological observations of each day of ten years (1878 to 1888) had been compared with the number of cases (8,036) noted in the German dispensary, and with the mortality of this ailment in New York (31,638 deaths in children under three years of age in Manhattan and the Bronx).

The results of this comparison were:

1. Gastroenteritis in children becomes epidemic in this city as soon as the lowest atmospheric temperature of the day reaches 60° Fahrenheit and remains at or above this figure, usually from June 15 to October 15.

2. The persisting high atmospheric temperature permits the rapid growth of organisms, and thereby the productions of toxins in the milk during its transportation, and thus causes epidemic gastro-enteritis (summer-complaint).

The logical inference of these, then newly-established, facts was *to stop all milk-feeding in gastro-enteritic children until the infection of the alimentary canal had been disposed of,* a rule I have followed since.

In the treatment of typhoid fever patients suffering from diarrhea this same thought soon forced itself forward. Practical tests showed that typhoidal diarrhea stopped much more readily without than with a milk diet. But, furthermore, it was noticed that the fever and the remaining symptoms of systemic infection were lowered from day to day, but only while milk was withheld. On renewing the milk diet, the temperature, the pulse rate, the tympanites, and the diarrhea soon reached their former heights.

These observations tempted me to feed the next typhoid patients with strained soups and water, without milk. The results of these tests (made in the fall of 1889) were so marked that the writer came to the conclusion that milk could do but harm in typhoid fever.

Cantani had used regular irrigations of the colon with a 1 per cent. tannic acid solution during an epidemic of Asiatic cholera in Naples in 1861. At Mosler's clinic (in Greifswald) this method was tried later on in typhoid fever, and Backhaut (one of the assistants) reported favorably on this plan in the *Deutsche medizinische Wochenschrift,* July, 1889. The possibility of destroying the typhoid organisms by the tannic acid was questionable, as it could not reach the small intestine, but the removal of the feces by repeated irrigations of the lower bowel appeared rational. For this purpose plain warm water could do the same work, and even better. The success of the first trials of this plan proved the correctness of the supposition, for the rectal irrigations with plain warm water have proved themselves in my hands, since the fall of 1889, to be but the rational supplement to the fluid diet without milk in every case, for both reduced the amount of typhoid poison in the patient. At first rectal tubes were used, but were soon discarded. Typhoid ulcers may be present in the rectum, even in mild cases.

Since October of 1889 the author has been enabled to test the above plan of typhoid treatment in the first medical division of St. Francis' Hospital. The following rules were followed in all cases:

1. If nausea were present on admission, the stomach was washed out. Then two doses of calomel, each containing two grains, were given within two hours.

2. Rectal irrigations with three pints of warm water were begun at once. In severe cases every three, in milder ones every six, and in mild cases every twelve hours. Bowel hemorrhage, appendicitis, and perforations were the only contraindications.

3. During the first day of treatment nothing but cold water was given.

4. From the second day on, one-half pint of strained rice-, oatmeal-, or barley-soup, containing the extract of half a pound of meat and the yoke of a fresh egg, well spiced, were given every three hours, five times daily. During the night cold water alone was offered.

5. During the first three days of treatment the patients were not urged to swallow all of their soup, but were persuaded to drink cold water every hour by day and by night. From the fourth day on, strained pea-, lentil-, potato-, and tomato-soup with rice were added to the menu. The desire for more food, coming in uncomplicated cases not seldom on the fifth or sixth day, was met by giving the soups thickly made. The lower the fever and the more marked the hunger, the thicker the soup. To very hungry patients two or three zwiebacks were given with their soup at the end of the first week. Orange juice was given in water three times daily. Egg albumin was not given, on account of the possibility of forming toxins.

6. Before each meal fifteen to twenty-five drops of hydrochloric acid were given in one-half ounce of water.

Alcohol was given only to topers. Cold baths

*Read at the meeting of the German Medical Society, April 6, 1908.

were *never* employed, even in hyperpyrexia. Opium was used only in bowel hemorrhage.

During complicating pneumonia sixty to one hundred and twenty drops of 20 per cent. camphorated oil were injected hypodermatically, twice daily. No other medication was used.

The results of this plan of treatment were the following:

1. Nausea, headache, delirium, insomnia, tympanites, and diarrhea disappeared in most cases after two to three days, and did not recur later on.

2. In uncomplicated cases the temperature began to drop after twenty-four to forty-eight hours daily by ½° to 1° F., and reached 99° F. in the rectum on the morning of the ninth, tenth, eleventh, or twelfth day of treatment, irrespective of the duration of the attack before admission. In a smaller number of cases this occurred within the first week of treatment.

3. In cases admitted with complications (like pneumonia, nephritis, and phlebitis) the intestinal symptoms (tympanites and diarrhea), as well as those of systemic infection of the nervous system (delirium, headache, and insomnia) usually disappeared as readily as in uncomplicated cases, while the temperature, the pulse rate, and the respirations remained at the height characteristic of the local processes.

4. The complications disappeared more readily than under the former milk diet.

5. Later complications very seldom developed in cases admitted without complications.

Statistics are tiresome and will be here but briefly dealt with. The reports on three hundred and thirty-eight typhoid patients treated by the author during the last nineteen years in hospital and private practice are at hand. The report published seven years ago comprised one hundred and fifty-three cases, of which seven patients died in the hospital. Three of the latter were admitted in a moribund condition, and four suffered from bilateral pneumonia when treatment began (*Archives of Pediatrics*, September, 1900). Since then one hundred and eighty-five typhoids (showing positive blood tests) were treated, one hundred and thirty-nine in St. Francis Hospital, and forty-nine in private practice. Of these, six patients died in the hospital, none in private care. Adding the cases of my last report to those of this one, we have three hundred and thirty-eight cases with thirteen deaths, a mortality of 3.1 per cent.

A better insight into the action of this plan of treatment is furnished by the following figures: During September, October, and November of 1906 and 1907, sixty-one typhoid patients were treated, fifty-one in the hospital, and ten privately. Of these, nine cases reached the normal temperature within one week. Twenty cases reached the normal temperature within two weeks (of these, three had pneumonia, and three were sent in with bowel hemorrhage and therefore could not be irrigated). Eighteen cases (all complicatel) reached the normal temperature within three weeks. Eighteen cases (all complicated) reached the normal temperature within four weeks. Four far advanced cases reached the normal temperature within six and seven weeks. These last four cases were all septic on admission, and, aside from pneumonia and nephritis, presented such symptoms as singultus, hemophilia, and multiple abscesses.

Of the sixty-one patients, one died three days after admission. His complications were bilateral pneumonia, acute nephritis, and alcoholism.

This report proves that the majority could not be classed among the mild cases.

In view of the results of this plan of typhoid treatment, the following conclusions are submitted:

1. It abbreviates the attack and ameliorates the symptoms by the constant reduction of infectious material.

2. It prevents complications; and

3. It reduces the mortality.

The first report on this typhoid treatment was published by the author in the MEDICAL RECORD of September 12, 1891. Further reports were made in the *New York Polyclinic* of March, 1893, the *Medizinische Monatsschrift* of July, 1894, and the *Archives of Pediatrics* of September, 1900.

Since the fall of 1889 this plan has been recommended to the attendants at my clinic at the New York Polyclinic.

William Osler had mentioned the author's suggestion of irrigating the bowel in typhoid in his textbook on the "Practice of Medicine," published in 1896. Encouraged thereby, I sent a dozen typhoid histories from St. Francis' Hospital, with the accompanying temperature charts, to Baltimore, with the request to try this plan in a few cases. Osler's answer stated that he was so well pleased with his own results that he would not try this plan, and (verbally) "in hospital practice milk is by far the least expensive food in typhoid."

In his publication on Typhoid Fever in Baltimore (Johns Hopkins Hospital Reports, Vol. IV.), Osler said: "Milk is of all fluids the most susceptible for infection, and forms a culture medium of the very best kind, particularly for typhoid germs," and on page 229 he reports: "Milk is the staple article of diet (for typhoid patients) of which from three to four pints are given in twenty-four hours."

Strümpell, in the sixteenth edition of his textbook, published in 1907, on page 30 states: "The diet of typhoid patients must be fluid and yet nutritious. Milk is efficacious and must always be given, but, to my sorrow, is taken by but few patients with a relish on the long run."

On page 852 of the *Journal of the American Medical Association* of September 7, 1907, the following statement of William Hallock Park is mentioned: "Milk makes the bowel contents more suitable for the preservation of the typhoid bacilli, until passed externally."

In conclusion, but two questions:

1. Is it conceivable that after the primary invasion of the typhoid bacilli from the infected food into the intestinal tissue and the blood of the patient, further invasion ceases?

2. If such an assumption is preposterous, is it rational constantly to supply the bowel contents with the best possible food for the typhoid bacilli? Is this not pouring oil on a fire?

114 EAST FIFTY-SEVENTH STREET.

A MILK-FREE DIET IN TYPHOID FEVER.*

BY CYRUS J. STRONG, M.D.,

NEW YORK.

VISITING PHYSICIAN TO BELLEVUE HOSPITAL.

IN the treatment of a disease so prevalent, so widely spread geographically, so insidious in its invasion, and so treacherous in its course as typhoid fever, any method which promises prevention or amelioration of distressing or dangerous symptoms demands careful consideration. The advocacy of any diet in

*Read at the meeting of the German Medical Society, April 6, 1908.

typhoid which shall exclude milk is indeed radical, for milk has long been regarded as the sole or principal food, other articles being added to prevent monotony or because they subserved individual preference, emphasis always being laid upon the fact that in milk alone all the nutritive requirements are to be found in their most digestible form, yet the results obtained under the above plan seem to demonstrate the fallacy of this opinion.

We have all repeatedly noted untoward symptoms arising from the imperfect digestion of milk in typhoid fever, even when the patient was fond of it, while we find but few who manifest no distaste at any period of the disease, provided they retain a sufficiently normal mentality to express any preference. The facility with which bacterial activity occurs in milk should long ago have given warning of the dangerous complications almost inevitable under the conditions present in typhoid, and its continued use is, to my mind, simply another instance of the tremendous influence exerted by established usage in our profession.

I am convinced that in a milk-free diet we eliminate one of the principal sources of danger, and markedly modify the course of the disease to a milder type, less prone to complications. My conviction rests upon a much firmer basis since the reading of Seibert's reports, detailing the results obtained in a series of cases extending over a long period with uniformly satisfactory results.

When I entered upon my service at Bellevue Hospital last May, there were in the wards of the Fourth Medical Division five typhoids who had been given no milk since entering the hospital, this method of treatment having been adopted by my predecessor, Dr. Alexander Lambert, to whom, and Dr. Charles G. L. Wolf, who made all the determinations regarding nitrogen balance and nutritive equilibrium during my entire service, I am deeply indebted. The appearance and general condition of these patients in one ward (there were four in consecutive beds) differed so radically from that presented by any similar number of typhoids I had ever seen during the eighteen years of my connection with Bellevue Hospital, that, had I not seen the charts, a diagnosis would not have been possible from mere inspection. Three of these patients, though at the fastigium of the disease, required no medication or baths, being entirely free from the toxemia usually found at this period, yet having been admitted with high temperatures and other evidences of at least average infection.

Since that time all typhoids coming under my care have been treated as follows: On admission, calomel, gr. 3 to 5, in divided doses, followed by 1 dram of magnesium sulphate. Diet to consist of 8 ounces of some meat broth, prepared at a temperature below the coagulation point of albumin, in order that a minimum of bulk should contain a maximum of nourishment; soda crackers in hospital, zwieback or breakfast biscuits in private practice, with butter, if desired, alternating every three hours with 6 or 8 ounces of gelatin in the form of the so-called calf's-foot jelly, or the same amount of boiled rice, with butter and sugar added in varying amounts, depending upon the demands of nutrition and the condition of digestion. We thus meet the food requirements (proteid for cell repair, fat and carbohydrate in increased amount to maintain body weight) at a reasonable standard, and provide for the excessive metabolism, consequent upon prolonged illness with high temperature. Water was given freely throughout the entire course of the disease.

Much less objection was made to this diet than when milk constituted the major part of the nourishment, and by exercising a little care and not crowding the diet at first, the patients were better satisfied, and the complaint of having had "nothing to eat" was infrequently heard.

This diet differs somewhat from that employed by Seibert, but the variation is less than might appear at first sight. Enemata were not given as an integral part of the treatment, being used only to overcome slight constipation. Pepsin and hydrochloric acid also were given only when indicated. Cold baths, usually in the form of bed baths, were employed to keep the temperature below 103° F., but the necessity for their use was greatly diminished, some patients requiring but one or two during the entire illness. Stimulation, by either strychnine or alcohol, was seldom required, in spite of the fact that nearly every patient exhibited at some time fairly marked dichrotism of the pulse, which was, however, unaccompanied by any untoward symptom. For hemorrhage calcium lactate was given in 20 grain doses.

Patients under this treatment exhibited far less prostration; their faces lacked the dusky flush so characteristic of typhoid; the tongue soon became moist and clean, or remained but slightly coated at the base; no tympanites or marked diarrhea persisted except in one fatal case; loss of flesh was markedly diminished, and in every respect the patients presented an appearance so unusual as to cause comment on the part of those professional friends who visited the wards at my invitation.

Sixteen cases were thus treated in Bellevue Hospital, with three deaths, and one in private practice with recovery. The following is a brief report of the fatal cases:

Case I. Male, history of syphilis and marked alcoholism. Urine loaded with albumin and casts, tympanites and diarrhea persistent. Died on the tenth day in the hospital. Autopsy revealed necrotic areas surrounding the ulcerations. Kidney markings very indistinct.

Case II. Male, alcoholic history. He soon gave evidence of profound toxemia with persistent temperatures to 105° F., not yielding to baths. Cardiac action bad from the time of admission. Died on the ninth day. No autopsy permitted.

Case III. Female, markedly prostrated on admission. Heart action remained poor in spite of liberal stimulation. Peripheral neuritis in the lower extremities. Died on the eighth day. No autopsy.

Of the thirteen cases, one had a single, fairly profuse hemorrhage, one a general bronchitis, two suffered mild relapses. Convalescence in all cases was more rapid than usual, though I am unable to report that there was any shortening of the duration of the disease.

Through the courtesy of Dr. Alexander Lambert, who opened the discussion on Dr. Seibert's paper, I am permitted to report the results in twenty-six cases treated by him on the same plan, twenty-two in Bellevue Hospital, and four in private practice. Two hospital patients died with complicating pneumonia and delirium tremens. I may add that Dr. Lambert's advocacy of this method is most enthusiastic.

In conclusion, while I have thus treated but seventeen cases on the milk-free diet, even that small number has shown results which to me thoroughly justify its adoption, and a comparison of the two methods will, I am convinced, if tried simultaneously, lead others to the same conclusion.

60 West Seventy-fifth Street.

REMARKS ON MILK-FREE FLUID DIET AND RECTAL IRRIGATIONS IN TYPHOID FEVER.*

By ROBERT C. KEMP, M.D.,

NEW YORK.

VISITING PHYSICIAN FOR GASTROINTESTINAL DISEASES, RED CROSS HOSPITAL; CONSULTING PHYSICIAN MANHATTAN STATE HOSPITAL, AND GASTROLOGIST TO THE WEST SIDE GERMAN DISPENSARY.

During the past few years we may say there are practically three methods of diet advocated in typhoid fever, viz.: (1) the full diet method, if I may so call it; (2) the old method with milk as a standard, and (3) Seibert's method, fluid diet without milk, by means of strained soups.

Regarding the first method, I will briefly quote Ewald in an article from Von Leyden's *Zeitschrift für diatetische und physikalische Therapie*. "During recent years the opinion has repeatedly been brought forward that typhoid patients should be given, during the course of the fever, a food rich in albuminous substances. In this way, it is argued, the resisting power of the organism is increased, the course of the disease is made less severe, and the period of convalescence is shortened. Gornicki, Barrs, and Puritz have indeed gone so far as to recommend that at the height of the fever a diet consisting of hard boiled eggs, chopped up finely, cutlets, white and brown bread, and the like, should be given and claim that by such means they have obtained good results. My conscience as a practitioner would not permit me to follow this advice. If anyone examined, as I did, hundreds of typhoid intestines post mortem, and thus convinced himself that in an apparently mild and harmless course, there may be many and deeply penetrating ulcers, then he could not so easily take upon himself the responsibility of giving a typhoid patient a diet of such a solid character, which can by no means remain, so far as the mucous membrane is concerned, without disadvantageous effects. I cannot help thinking that it is particularly fortunate that the observers, whose names have been mentioned in this connection, have not had to contend with very grave consequences, and for my part I should never think of prescribing for my typhoid patients a so-called course of diet, viz., meat with its indigestible fibers and vegetables, at an earlier period than six or eight days after the fever had ceased." There is no mistaking Ewald's point of view.

Nevertheless, there are to-day some prominent physicians who still advocate the liberal diet; one of whom, I am informed by a mutual friend, first tried the method on his mother-in-law who made a prompt recovery. As Ewald remarks, they must have been particularly fortunate. I have had one experience from following suggestions as to giving a more liberal diet in typhoid, which resulted in a relapse and the death of my patient. This occurred several years ago and the experiment will never be tried again with my consent.

Regarding the second method of diet, the use of milk as a standard in typhoid fever, I would speak at greater length. Dr. Seibert has already called to your attention how readily organisms grow in milk and how rapidly toxins are developed; he also has referred to the views of Osler and Park, as to the susceptibility of milk to infection from typhoid and how suitable it is for a culture medium. Osler in his recent work on Practice, 1907 Edition, states that in milk the typhoid bacilli undergo rapid development.

*Read at the meeting of the German Medical Society, April 6, 1908.

There are additional reasons, moreover, against the employment of milk in this disease. During the active stage of typhoid, especially during the periods of higher temperature, there is marked derangement in the secretory function of the stomach —a diminution and at times an absence of free hydrochloric acid and a lessening of the pepsin and rennet ferments. This is all conducive to the production of fermentative and putrefactive changes in the milk. It will curdle, none of the digestive transformations will occur, and it will be either vomited or more frequently pass by the bowel as a mass of curds. I am cognizant of one case at least in which the autopsy demonstrated a greatly distended stomach, filled with a mass of curds, evidently the collection of several previous feedings.

This brings us to a second feature—the relation of the motor power of the stomach to milk—and to the various foods soluble in water, such as bouillon and strained soups.

In health, Leube determines the scale of digestibility according to the length of time the food remains in the healthy stomach, as under such conditions the secretory and motor functions generally go hand in hand. In disease, however, as in the case of typhoid fever, with diminished digestive function, the length of stay of the food in the stomach would bear more on the question of putrefaction, or fermentive changes.

In health, water and foods soluble in water, such as bouillon and strained soups, pass most rapidly from the stomach; 200-250 c.c. are evacuated in 1 to 2 hours. Equal quantities of raw milk take at least an hour longer for complete evacuation—as demonstrated by lavage. Boiled milk is passed more rapidly than raw milk, cooking altering the curd formation.

In dilatation of the stomach, the same rules hold good, but the periods are longer, depending upon the degrees of motor insufficiency.

In various experiments during my service at Ward's Island, we found that if the milk were diluted one-half with water, the residuum found at a certain period was just about half what it was when pure milk was used, and there were fewer curds. If diluted two-thirds with water, a correspondingly increased quantity was passed from the stomach into the intestine and a smaller residuum was found. In fact, as you know, this method of milk dilution is practised in infant feeding for obvious reasons.

It is therefore evident that in the acute stage of typhoid fever, with diminished digestive power, due to diminution or absence of free hydrochloric acid, especially as raw milk under normal conditions leaves the stomach quite slowly, what the results would be as regards fermentative and putrefactive changes.

Moreover, the motor function of the stomach is generally diminished during the acute period of typhoid, whether diarrhea or constipation be present. In New York we have quite a few cases of the constipated type and in these I have found the diminution marked. Stasis we know is extremely conducive to putrefaction.

During the recent Spanish-American War in Cuba members of the Red Cross Society, under the direction of Dr. A. Monae Lesser, treated all typhoid cases by strained broth, malted milk, and rectal irrigations, avoiding the use of milk, and with excellent results. This was in effect Seibert's method, though they did not then know of his experiments which antedated the Red Cross method

by some years. Dr. Lesser has to my knowledge carried on in the past numerous experiments as to the secretory and motor functions of the stomach in typhoid fever, so that my own observations are merely confirmatory of this work.

Having been reared on the "old milk diet" theory my "regeneration" has been a gradual "evolution," and from careful observation in numerous cases I can fully substantiate all that Seibert claims for his method—the abolition of tympanites, fewer complications, the more rapid reduction of temperature, etc.

My only modification of his method is in cases of complicating nephritis of active type, where beef broths are omitted; but the strained farinaceous gruels are kept up, and occasionally I use malted milk made up with hot water. Moreover, I have been employing of late in my gastrointestinal cases a sterilized milk albumin product containing glycerophosphoric acid, which is soluble in water and has been demonstrated by Ewald to have considerable nutritive value and to be readily absorbed in typhoid fever. In such cases I believe it would be of considerable value.

The use of rectal irrigations is one of the most important features in the treatment of typhoid fever, and this I have myself advocated since 1896. Personally, I have generally employed the short recurrent tube and normal saline solution. The only contraindications are hemorrhage and peritonitis. By the irrigations the small intestine is emptied out into the large intestine, and this in turn cleared out; absorption from accumulation in the rectum is prevented, and hence toxemia is lessened and the temperature is reduced; gas, if present, is removed from the bowel; the large intestine is kept clean, and elimination of the toxins, through the diuretic action of the injections on the kidneys, is promoted.

It may be of interest to you to learn that in the new Red Cross Hospital, a small but well-equipped institution with the present capacity of about fifty beds, the following routine treatment has been established for typhoid fever: Water *ad libitum*, rectal irrigations, *no milk*, strained soups and broths, dilute HCl, orange juice, no alcohol.

Camphorated oil, strychnine, digitalis, and caffeine are used only if indicated.

Whenever the temperature reaches 102.5° F. or over, *no food* is given, only water until defervescence below this point.

This method of diet has been employed for at least ten years. Sponging, or friction baths (Brand) are allowed, but have not been found to be necessary, when the above treatment has been carried out. The method employed by the Red Cross Hospital markedly corresponds to that originated by Seibert.

We know, of course, that new methods always meet with opposition, and that any man straying from the narrow path of prejudice and custom is often held up to unjust opprobrium and even to ridicule. It is the man of original ideas, and not the one "in the groove," to whom we owe our advancement in science.

In conclusion, let me assure you that the method described this evening by Dr. Seibert, the result of nearly twenty years of careful investigation, is based on sound scientific principles, and I venture to predict that the time will come when it will be taught as the proper method of treatment for typhoid fever, and due credit will be given him, to whom it properly belongs.

107 East Fifty-Seventh Street.

CLINICAL CHARTS OF A CASE OF QUARTAN MALARIAL FEVER OBSERVED IN WEST AFRICA, WITH COMMENTARY.*

By F. CREIGHTON WELLMAN, M.D.,

BENGUELLA, WEST AFRICA.

Infection with the quartan malarial parasite is a comparatively rare condition in the part of Portuguese West Africa studied by the writer, namely southern Angola. In a series of 531 cases of infection studied by me[1] only fourteen cases showed this form of parasite, all the remaining fevers being due to invasion by malignant parasites. Benign tertian has not yet been seen. In view of the local rarity of quartan fever the writer, some time ago, decided to observe carefully the progress of a case of the disease. The greater part of the working hours of one week were given up to the gathering of the data exhibited in the following charts. The case was observed for its intrinsic interest, the writer having no thesis to defend nor other aim than the first-hand acquisition of clinical facts regarding the disease as it exists in this district, from whence it had never been reported prior to a communication from the author of this paper[2]. Notes from a medical diary and a few additional observations in the form of comments have been added to the charts.

Case Notes.—Milemba, twenty-five years old, male, a Bantu, had always lived at a point about 1,300 meters above sea level. Being partially crippled he had never been into the more unhealthy lowlands along the coast. He had suffered from slight fevers from time to time all his life but never had severe ones. Was taken sick two days before I saw him.

When first seen the patient had a temperature of 103° F., pulse, 90; respiration, 28. The spleen was slightly enlarged and somewhat tender. The blood was slightly alkaline by Haycraft-Williamson's method and showed in benzol-chloroform mixture a specific gravity of about 1.055. As to its tonicity I only tested it by adding to it a 0.41 per cent salt solution which, however, gave no hemolysis. On microscopical examination, quartan gametes and a few small ring forms were seen, with one or two pigmented leucocytes. The erythrocytes were normal in shape and size and no nucleated red cells were seen. Counted by the Thoma-Zeiss method, the number of erythrocytes was 4,700,000; leucocytes 7,000, hemoglobin index by Gower 90. A differential leucocyte count gave the following percentages (about 500 counted): Lymphocytes, 33 per cent.; large mononuclears, 29 per cent.; polymorphonuclears, 27 per cent.; eosinophiles, 11 per cent. The patient was a plump, well made man weighing 154 pounds (English) and was 5 feet 8¾ inches tall. He walked with a limp, having lost the toes of his right foot.

Method of Study.—The following routine was followed throughout the observation. The temperature and pulse were taken twice daily, always at the same hour. The blood for microscopical examination was also taken twice a day as near as possible at the same hour each day. Two wet and two dry specimens were always made, the latter to be stained, one by Leishman's modification of

*Read by title at the fifth annual meeting of the American Society of Tropical Medicine, held in Baltimore, March 28, 1908.

[1]Atti della Societá per gli Studi della Malaria, Rome, 1907, pp. 29-58. 1 plate and 8 figures in text.

[2]Journal of Tropical Medicine, London, November 1, 1905, p. 319.

Romanowsky and the other with hematoxylin and eosin. The number of red and white cells was counted on the Thoma-Zeiss hemocytometer. On two occasions the result was compared with readings on the hematokrit. The hemoglobin index was taken by Gower's hemoglobinometer. The differential leucocyte counts were made on slides stained by hematoxylin and eosin. The patient was weighed daily at the same hour, and the amount of urine passed was measured and the number and size of stools noted. All the fluids ingested by the patient were measured and the solids weighed. No medicines were given or allowed.

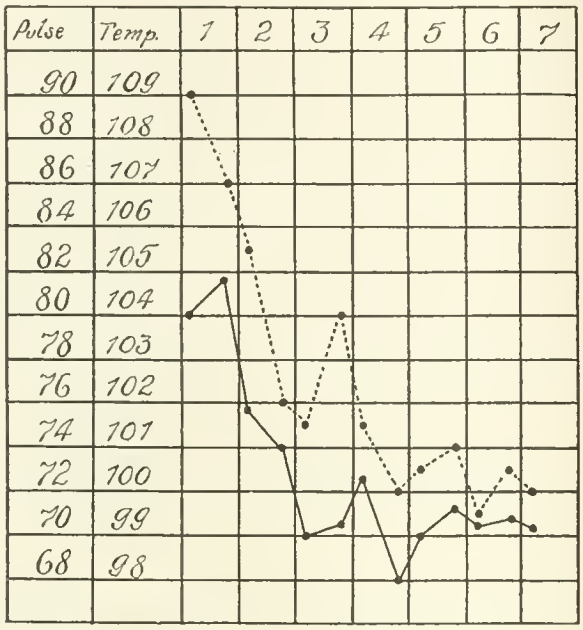

CHART I.—Pulse and Temperature. The continuous line indicates the temperature as taken in the mouth.

Commentary on Chart 1.—The temperature curve is very different from the classical quartan type.

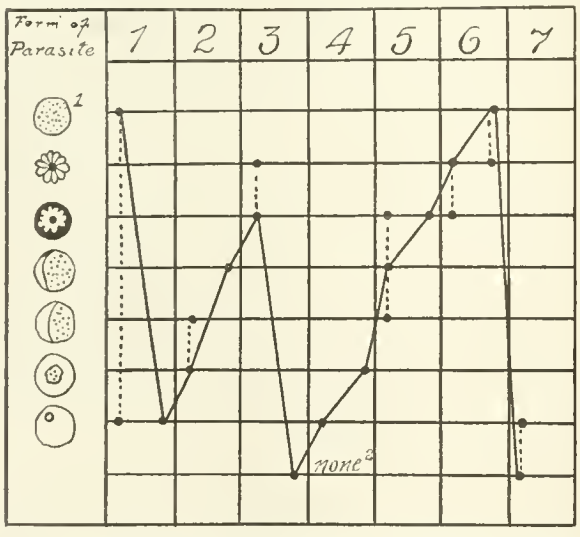

CHART 2.—The Shapes of the Parasite Seen in the Blood at Different Times. The line representing the parasites refers to the developmental stages observed and not to the abundance of parasites in the blood. The forms of the parasite are shown at the left of the chart. [1]Gamete. [2]A few parasites were found on the evening of the third day in a thick film preparation.

In other cases which I have seen in West Africa there was even slighter rise of temperature (not over 100° F.) and in one or two cases no elevation of temperature at all, although the developmental cycle of the parasite went on steadily and regularly in the blood. In the case before us there was not, I believe, a double infection. Of course this is hard to pronounce upon categorically, but the small ring forms (with which alone malignant parasites could be confounded) did not seem to be in excess of their usual proportion and did not appear at the time one would expect them in a tertian. Close search was also made for crescents and other signs of double infection. Rest in bed seemed to be the chief factor in calming down the clinical manifestations. The accelerated pulse and respiration slowed down as the temperature fell. After the first day the patient was quite comfortable and by the third day wanted to get up.

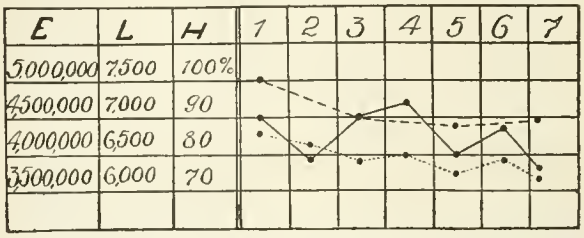

CHART 3.—Comparative Numbers of Erythrocytes and Leucocytes, with Hemoglobin Index. The continuous line indicates the erythrocytes (E), the broken line the leucocytes (L), and the dotted line the hemoglobin percentage (H).

Commentary on Chart 2.—It will be seen on comparing this chart with Chart 1, that the sporulation of the parasite went on without the slightest relation to the temperature and pulse. This chart does not show all the forms seen in the blood at any one time, but only the form which preponderated during each stage. I have tried with dotted lines, however, to indicate other forms which were numerous and to connect them with the chief form. For instance on the morning of the first day segmenting forms could be seen with the gametes as well as small ring forms and even a few larger ones. The time and sequence of the development stages of the parasite in this case were not so regular and typical as I have seen in cases in Europe.

Commentary on Chart 3.—This chart shows that both the absolute and comparative numbers of the red and white corpuscles remained practically unchanged throughout the period. It will be seen, however, by comparing the erythrocyte count and hemoglobin index that the oxygen-carrying power of the blood was rather lowered, probably as a result both of hemolysis and corpuscular deficiency. The leucocytes, already scant, as is often the case in malaria, fell a little. The further behavior of the leucocytes is shown in the next chart.

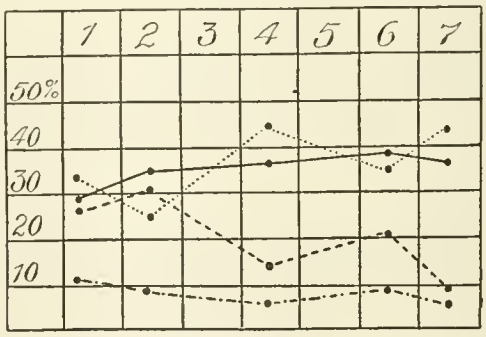

CHART 4.—Results of Differential Leucocyte Counts. The dotted line indicates the percentage of lymphocytes; the continuous line that of large mononuclears; the broken line that of polymorphonuclears, and the dotted-broken line that of the eosinophiles. About 500 were counted each time. N. B. The "transitionals" were always counted with the polymorphonuclears.

Commentary on Chart 4.—The differential leu-

cocyte count shows no marked phagocytic tactics. The increased percentage of large mononuclears is characteristic of a malarious country. The cosinophiles and large mononuclears appear to be the most constant, but food taking and other factors may very well account for the polymorphonuclear

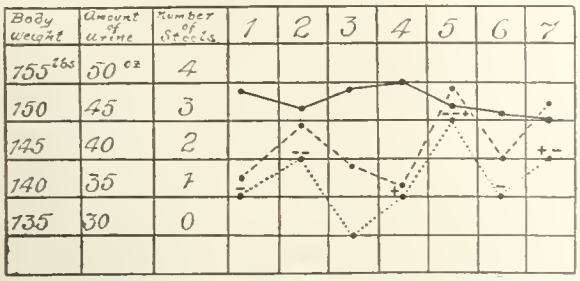

CHART 5.—The Changes in Body Weight Compared with the Amount of Urine and the Number of Stools Passed During the Period. The continuous line indicates the body weight in English pounds; the broken line the number of English ounces of urine passed in twenty-four hours; the dotted line the number of stools in twenty-four hours (+ denotes a large stool; − a small stool).

and lymphocytic variation. The number of eosinophiles is not unusual for natives of this country (where some sort of helminthiasis is almost universal). I have frequently seen as large a proportion in individuals apparently enjoying the best of health. Entozoal infection probably accounts for such conditions.

Commentary on Chart 5.—The body weight decreased but slightly during the attack. The smaller amount of urine passed during the first part of the attack is probably to be explained by the fact that the patient perspired more freely at that period than later. The urine became much lighter in color during the last three days of the observation. This chart should be compared with the following one.

Commentary on Chart 6.—The appetite increased as the patient grew better. The ingestion of liquids was the greatest on the first and fourth days of observation, and lowest on the second. The food and drink as a rule consisted of a fermented native gruel called "Ochisangua," made of meal from maize (*Zea mais* L.) and cassava (*Manihotutilissima* Pohl) mixed with water and the juice of a root called "Ombundi" (*Erioscma muxiria* Baker). For the last three days of the observation some solid food was taken with this.

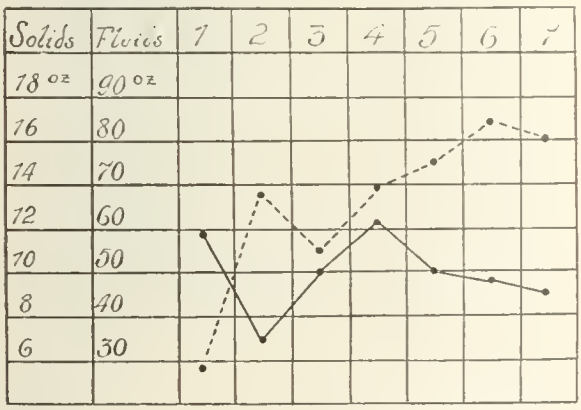

CHART 6.—Comparative Amounts of Fluids and Solids Ingested During Each Twenty-four Hours of the Disease. The continuous line indicates the fluids in English ounces; the broken line the solids in ounces.

General Commentary.—The foregoing is an attempt to add to our knowledge of the behavior of the quartan malarial parasite in tropical climates. Some points of interest brought out are: (*a*) the effect of warmth and rest in lowering the temperature and pulse rate; (*b*) the somewhat irregular sporulation of the parasite; (*c*) the relatively little damage done to the blood; (*d*) the constancy of the relative proportions of the leucocytes; (*e*) the small loss of body weight, and the general well-being of the patient without medical treatment; (*f*) the morphological identity of the parasite with the quartan parasite of other countries.

In conclusion, I may say that while the quartan fever of West Africa is the same as that of temperate climates, yet the mischief done is far less. It should be mentioned here that the patient declared himself perfectly well before he was discharged, and on his discharge immediately began manual labor. It would seem that in negroes of tropical climates who have acquired sufficient immunity to be generally fever-free in districts swarming with malignant malaria, such a benign disease as quartan (which in Europe gives rise to fevers quite severe enough) is a comparatively negligible factor.

THE RELATION OF TUBERCULOUS COWS TO TUBERCULOSIS IN CHILDREN.

BY WILLIAM LELAND STOWELL, M.D.,

NEW YORK.

VISITING PHYSICIAN TO THE NEW YORK CITY CHILDREN'S HOSPITAL.

Two subjects closely related are engrossing the attention of scientific physicians and students of social economics. One is pure milk as food for children and adults; the other is tuberculosis which cuts short the life of both old and young. Tuberculosis causes about 120,000 deaths annually in the United States—that is more than one-tenth of the total mortality. If our entire army and navy should be destroyed in a year the numerical loss would not equal that caused so quietly by tuberculosis. Domestic animals, especially cattle, develop the disease in large numbers. Reports from the slaughter houses in Berlin (1892-3) showed that 15 per cent. of beef cattle were tuberculous. Dr. Veranus Moore of Cornell University estimates that there are now 440,000 such cows in New York State, and Dr. Smith (*Boston Medical and Surgical Journal*, January 18, 1906) says: "The herd of a public institution in Massachusetts that is not infected to a greater or less extent with tuberculosis is the exception and not the rule." The diseased cow is spoken of as the "chief manufacturer and disseminator of tubercle bacilli" and as being more dangerous even than the tuberculous man. We are not prepared to say whether this is proven or not, but it indicates the importance of the subject.

The etiology of tuberculosis in man and its relation to the same disease in animals have engaged students for many years. While Vogel was laying stress on heredity, Villeman, in 1865, was announcing tuberculosis as a specific infection, which he proved by inoculating rabbits (Blackader). Chanreau, 1868, fed calves with milk containing sputum and tuberculous flesh, causing them to become tuberculous (Blackader). This seems to have been the first of ingestion experiments. Blackader (*Boston Medical and Surgical Journal*, Vol. 114, No. 25, p. 665) gives an instance of ingestion origin in the case of the daughter of Dr. Gosse of Geneva. She was seventeen years old and spent each Sunday in the country where she drank freely of warm milk. She died after ten months' illness. Four of the five cows on the farm were found to be tuberculous and two of them when killed had

tuberculous udders. Unfortunately man has been directly inoculated at autopsies, notably Prof. Jensen of Copenhagen and Dr. Thomas Walley of Edinburgh. In 1882 Koch declared the specific cause of tuberculosis to be the bacillus with which

Fig. 1.—From a Case of Tuberculous Glands. *a.* Scars after removal of tuberculous glands; *b.* Pigmentation three weeks after tuberculin inoculation; *c.* Twenty-four hours after inoculation with tuberculin; *d.* Puncture not inoculated.

we are now too familiar. Since that time veterinarians and physicians have made countless observations. Sputum contains quantities of the germs and they are daily coughed into the air by the poor victim. The immediate family are most in danger because the bacilli are moist and virulent. Fortunately many lose their virulence by drying and by exposure to sunlight—otherwise the number of persons infected would be greater than it now is. Cadéac (*Le Bulletin Médical*, September 5, 1906) says that dust ground from tuberculous sputum is harmless both to the digestive tract and respiratory passages. This is reassuring to those who live in dusty cities.

Young animals are very susceptible to the bacilli, and children are included. Botz, quoted by Walsham, made 2,576 autopsies upon children, finding 27 per cent. of them tuberculous. At Escherich's clinic in Vienna 40 per cent. of the children coming to autopsy were tuberculous. The proportion in America is lower, at least in New York, for in a series of 726 consecutive autopsies at the Foundling Asylum tuberculosis was found in 8 per cent., *i. e.* 58. Of 319 consecutive autopsies in the Babies' Hospital tuberculosis was found in 44 or 14 per cent. (Holt, 1896).

Bacilli may gain entrance to the body by inhalation and go directly to the lungs. It was formerly supposed that the majority of cases of infection occurred in this manner, but recent animal experiments throw some doubt upon it. Schroeder and Cotton (U. S. Dept. Agriculture, Bulletin 93) produced pulmonary tuberculosis in a calf and three hogs by inoculating them with bacilli in the tail. All autopsy records of animals or persons tend to show that the lungs and bronchial glands are the favorite seat of development of tubercles without regard to the port of entry. Those taken into the digestive tract pass into the lymphatic vessels, thoracic duct, subclavian vein and thence directly through the heart to the lungs. Here they are filtered out and remain to develop tubercles in tissue most favorable to their growth. The frequency of the occurrence of tubercles in the intestine or mesenteric glands of children has forced the belief that they at least are primarily affected by bacilli in their food.

The certainty of infection depends partly upon the quantity of bacilli received and partly upon the resisting power of the individual. The first proposition has been well demonstrated in feeding and inoculation experiments. (See Bulletin 7, Animal Industry, U. S. Dept. Agriculture.) The latter statement is borne out by observation of many men with large experience in autopsies. Many bodies contain tuberculous glands that showed local infection and more extensive lesions often recovered from. It has been demonstrated that bacilli do not exist in milk properly drawn from cows having tuberculosis elsewhere than in the udder. Cows do not cough out but swallow the sputum brought up from their lungs and hence have abundant bacilli in the intestines. The feces of tuberculous cows are therefore as full of infective material as the sputum of persons. Schroeder and Cotton have demonstrated by inoculation and feed-

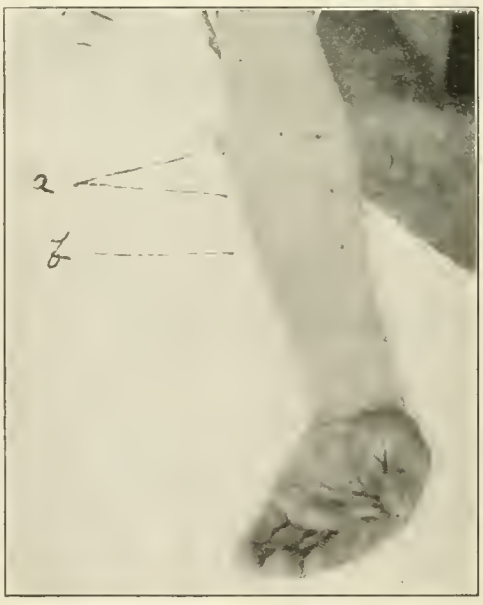

Fig. 2.—From a Case of Tuberculosis of the Hip. *a.* Twenty-four hours after inoculation with tuberculin; *b.* Puncture not inoculated.

ing that there is danger from this source (Bulletin 99). One does not need to go far among dairies to see that fecal matter often contaminates the milk. The cow keeps her tail switching about in warm weather and often lies upon a filthy floor at night.

An unusual opportunity has arisen for studying the relation of the milk of tuberculous cows and

children at the New York City Children's Hospitals on Randall's Island. This institution is located on an island of sixty acres lying practically in New York Harbor. Here are treated annually nearly 2,500 patients. The milk supply is in part from our own herd, and in part received in bulk from a large milk concern in the city. During the two years past the city supply has been pasteurized at 155° to 165° and reduced to a temperature of 45° before delivery to us. All wards known as sick wards, *i. e.* where there was acute illness, the quarantine wards, and those containing small children were supplied with our own farm milk, served fresh without pasteurizing.

Samples of the farm milk and that supplied from the city were examined each week by the Health Department. Great variations are shown, *e. g.*:

Oct.	5, 1905.	No sterilization	farm milk	70,000 bacteria per c.c
			city "	4,800,000 " "
			farm "	23,000 colonies "
Jan.	7, 1907.	Pasteurized....	city "	18,000 " "
			farm "	5,000 " "
Feb.	4, 1907.	Pasteurized....	city "	3,000 " "
			farm "	5,000 " "
May	6, 1907.	Pasteurized....	city "	800 " "
			farm "	72,000 " "
July	1, 1907.	Pasteurized....	city "	6,200 " "
			farm "	52,000 " "
Sept.	2, 1907.	Pasteurized....	city "	8,000 " "
			farm "	2,000 " "
Sept.	30, 1907.	Pasteurized....	city "	8,000 " "
			farm "	720,000 " "
Oct.	7, 1907.	Pasteurized....	city "	1,000 " "

These observations show that bacterial count gives no clue to the health of the cows, nor the character of the milk when it reaches the city full of bacteria to be pasteurized. The hospital's herd consisted of twenty-eight cows: four Holsteins, four grade Jerseys, two Durhams, and others, largely Ayrshire and native, also two bulls. The cows occupied a modern, well-built barn with cement floor, tight sides and ceiling, ample light and water supply, each having 780 cubic feet of air space; more than the standard 600 cubic feet. In December, 1902, the herd was tested with tuberculin and two diseased animals were found and killed. Occasionally a cow died or was killed, but the herd looked unusually well kept. In order to be sure that all were in perfect condition Dr. H. D. Gill of the State Department of Agriculture was asked to test them with tuberculin. On October 3, 1907, three temperature records were made of all the animals and tuberculin was injected in each. Six temperature records were made after injection and the rise of reaction was present in 27 of the 30, only three failing to react. Ten were found to have a cough. Five cows had been recently added to the herd, but three of them were found to be tuberculous.

All the animals were killed and careful autopsy records made. The three that failed to react to tuberculin were found free from lesions. Breed counted for little, although two of the three Holsteins were badly affected. Two grade Jerseys were slightly affected, having tuberculous retropharyngeal glands only, in one instance, and the other the same with tuberculosis of the intestines. The worst of all was a native cow with marked lesions of the lungs, pleura, liver, peritoneum, stomach, intestines, and spleen. Six had no pulmonary lesions. A native cow had lesions of the retropharyngeal gland and rather marked disease of the udder, without lesions elsewhere. The udder at the autopsy was considered tuberculous, but on histological examination proved not to be so.

One cow gave a suspicious reaction, and was found to have lesions of the mediastinal glands and a large abscess on the leg. Seventeen cows had marked pulmonary disease, eleven had disease of the posterior mediastinal glands, two of which did not have lesions of the lungs or pleura. Three had local lesions, two with retropharyngeal glands.

Dr. W. H. Park had samples of milk and feces taken from each cow for laboratory examination. Guinea pigs were injected with the samples, and in six weeks were killed. None of the pigs showed tuberculosis.

Only one cow had udder involvement. The farmer had discovered this bad udder in the summer, and therefore discontinued using the milk.

Bovine and human tuberculosis are interchangeable experimentally, and under suitable conditions may be so accidentally. Eber injected calves with mesenteric glands from children, and in many instances caused a virulent tuberculous process. Calves have been fed sputum with tuberculosis resulting. Feeding experiments are numerous (Allbutt's "System of Medicine," 1901, II, 204). The Royal British Commission on Human and Bovine Tuberculosis, in 1901, in summing up, says, "there can be no doubt that a certain number of cases of tuberculosis occurring in the human subject, especially in children, are the direct result of the introduction into the body of the bacillus of bovine tuberculosis," and in the majority of instances through the cows' milk.

Normal persons have a certain power of resistance against invading disease germs that varies little, but the opsonic power of hospital children is low because of their low vitality caused by faulty heredity and environment. Having both the children and the cows isolated and under control, there was presented an unusual opportunity to trace the relation between milk of tuberculous cows and children. Therefore the records were examined to learn just what wards received the farm milk and how many cases of tuberculosis they contained. During 1905, 1906 and up to October 1, 1907, there were treated 5,576 patients, of whom 190 died. Of this number 18 deaths, less than 10 per cent., were due to tuberculosis. Eleven children were idiots or feeble-minded, and therefore did not have the milk until already in the ward for acute illness and so were given the milk as special diet. Seven young children died, two having entered with spinal disease, one with a tuberculous hip, and one with tuberculous psoas abscess. A boy of fourteen years was admitted in March, 1906, with a diagnosis of anemia and died the following July of tuberculosis.

Jane Doe, age three years, was admitted June 25, 1906, with pertussis, and died two months later of pulmonary tuberculosis. This is the only case that appears definitely to have entered with a nontuberculous diagnosis, yet died of pulmonary tuberculosis. Even this fails as a proof case, because it occurred a year before the cow showed the diseased udder.

Attention was turned to the living to learn whether we had an unusual number of children with pulmonary or other tuberculous lesions. Physical examinations did not reveal an undue number, so we availed ourselves of the new tuberculin diagnostic tests suggested by von Pirquet and Calmette. In June, 1907, von Pirquet of the Children's Hospital in Vienna, advocated inoculating a drop of one-fourth of one per cent. solution of tuberculin into the arm of children. Three small punctures or scratches are made, one-sixteenth of an inch in diameter, two are inoculated and the third is regarded as a control. In six or eight hours

redness and swelling appear, extending one-third of an inch or more in diameter. In twenty-four hours there appear on the summit of the wheel-like spot a number of minute vesicles. After twenty-four or seventy-two hours of active reaction, the swelling subsides and gradually fades, though some pigmentation may remain for two or three weeks. The accompanying cuts illustrate well the cutaneous reaction.

The ophthalmotuberculin test was first applied to cattle, but Calmette about the same time tried it on man. One minim of a one per cent. solution of an alcoholic precipitate of old tuberculin is dropped upon the conjunctiva. In from three to ten hours congestion occurs, and the lacrymal caruncle becomes red and swollen. In marked reaction there is a slight fibrinous exudation and a sense of irritation as of sand in the eye. The irritation subsides in twenty-four or forty-eight hours.

We tried the new diagnostic procedure on all the children in wards that had farm milk exclusively. Seventy-seven children were subjected to the ophthalmic test, of whom nineteen reacted; thirteen of these were surgical cases and therefore expected to react; three were not suspected of tuberculosis, even latent.

All who reacted to the ophthalmotuberculin test were later subjected to the endermic inoculation after von Pirquet's method. Others were added, making eighty cutaneous tests. Of those who were treated both ways, six reacted to the ophthalmic, but not to the cutaneous test. Two had Pott's disease, one rachitis, and three were unsuspected epileptics.

Five cutaneous reactions were good where the ophthalmic reaction failed. They were cases of spinal caries, hydrocephalus, pulmonary tuberculosis, a questionable case of pulmonary tuberculosis, and an otitis media. Possibly some fault in technique accounts for these cases.

Six patients were inoculated a second time after three weeks. The second inoculation was as characteristic in every way as the first. The temperature rose about one degree in twelve of thirty-nine patients recorded before and after inoculation.

Many interesting conditions were noted in these tests. A group of twenty-one had the cutaneous test without the ophthalmic. Among them six reacted, three of whom had chronic ophthalmia showing bad nutrition from some cause. One child had a history of pulmonary tuberculosis, one year before, but appeared cured. One child had rachitis.

It is worthy of note that all the cases of rickets tested showed reaction. Walsham, referring to this subject, says (Channnels of Infection in Pulmonary Tuberculosis, 1905): "Rickets in certain cases unquestionably renders the tissues susceptible . . . bronchitis, atelectasis, and a distorted chest are a serious matter from the liability that exists to the production of caseous bronchial glands and subsequent tuberculosis."

The new diagnostic tests are quite sure to react in surgical tuberculosis, *i. e.* of bones and glandular affections. (See Figs. 1 and 2.) Four cases of otitis media reacted, though only one case was otherwise diagnosed tuberculous. Four others, patients who had been operated on for mastoid disease, failed to react, leaving the inference that this bone suppuration is not related to tuberculosis while middle ear suppuration is. Eight cases of spinal caries reacted and one case failed to react. Four cases of pulmonary tuberculosis reacted, and one failed to do so, being too far advanced. Two hip cases and five with tuberculous glands of the neck reacted well. The greatest surprise was in the marked reaction of four epileptics, three of whom are really adults and to all appearance in unusually good physical health. It is common for epileptics to die of phthisis, but these are far from it, showing no evidence of tuberculosis. Reaction occurred in about one-tenth of the unsuspected children inoculated.

Careful experiments have demonstrated that tuberculous cows give pure milk unless they have lesions in the udder (Bulletin No. 7, U. S. Dept. Agriculture). Similar observations and animal experiments demonstrate that tuberculous cows void numerous bacilli in feces (Bulletin 99, U. S. Dept. Agriculture). The lesson to be learned is that diseased cows should be eliminated from the milk-producing herd, and that great cleanliness will spare us from outside infection.

Conclusions.—Fresh, clean milk, when obtainable, is wholesome and more readily digested than when pasteurized. The danger of tuberculous infection from milk must be very slight, for in tracing the history of the children and the diagnosis on admission to the institution, there is no evidence of tuberculosis developing more often among those having the farm milk than among those in other wards having the pasteurized supply from the city. Less than 10 per cent. of the mortality was due to tuberculosis, and that according to the United States Census of 1900 is the ratio for the nation.

We cannot deny the presence of a tuberculous dairy and the presence of tuberculous children; but a careful analysis fails to show that one depended on the other.

160 West Seventy-third Street.

THE TREATMENT OF DISEASES DUE TO RESPIRATORY CATARRH.*

By WILLIAM MARTIN RICHARDS, M.D.,

NEW YORK.

My subject, this evening, is the treatment of several diseases, the course of which, at the time of our graduation, was considered to be very little influenced by any measures whatever. It is my purpose to show that during the last ten years this has changed to a very marked degree, so that now, most cases of respiratory catarrh, catarrhal deafness, asthma, pulmonary tuberculosis, hay fever, epilepsy, gout, rheumatism, lobar pneumonia, and last, but not least, homeliness of voice, face, and figure, can in most cases be permanently improved by methods now known to us. Several of these I call vacuum respiratory diseases because they are produced by an attempt to breathe through a nose which is partially stopped up, thus causing a partial vacuum in the respiratory tract. The diseases directly so produced are, I believe, catarrh of the nose, throat, and ear, and bronchial asthma. Indirectly, this vacuum is partly responsible for all the others.

Let us consider, for a moment, the result of a partially occluded nose: On inspiration we have a partial vacuum produced in the nasopharynx, and therefore in the Eustachian tube and middle ear, throat, and bronchial tubes. By partial vacuum I mean a pressure of less than 15 pounds to the square inch. By the force of the cardiac systole we have an equal pressure inside the blood-vessels all over the body. The pressure outside of these blood-vessels should be everywhere 15 pounds to the square inch. If over any area we have less

*Read before the Physicians and Surgeons' Club, Jersey City, N. J., March 17, 1908.

than this amount of pressure we get a dilatation of the blood-vessels over that area. The dilatation of blood-vessels means a hyperemia, which results in increased secretion, increased growth of tissue, and later, thickening and hardening of the tissue.

Let us see how this process results in the diseases that I have mentioned. The increased secretion in the nose and throat we know as catarrh; in the ear we know it as an abcess, or, when thickening and hardening have occurred over the ossicles, we know it as organic catarrhal deafness. Difference between pressure inside and that outside makes the ear-drum so tight that it will not vibrate, and results in functional deafness. In the nose we know the increased secretion as rhinitis; in the throat as pharyngitis; in the lungs as bronchitis, which last is admitted by the majority of observers to be the exciting cause of bronchial asthma and the opening of an avenue of access for pulmonary tuberculosis.

As regards the diseases and faulty conditions of which a vacuum is considered to be an indirect cause, we have epilepsy, hay fever, indigestion, gout, rheumatism, neuralgia, red, large, or bulbous nose, projecting front teeth, stooping shoulders, and lobar pneumonia.

As regards epilepsy: We have known for some time that in some cases the removal of adenoids from the nasopharynx resulted in its cessation. The explanation given for this by some observers was that the congestion produced by the nasopharyngeal vacuum caused pressure on the cribriform plate of the ethnoid; by others, the production of the toxins of the 66 varieties of germs irritating nerve endings and so producing convulsions.

I believe, in hay fever, that the best observers recognize three factors: (1) A neurotic individual, (2) a stopped-up nose, (3) some irritating substance in the atmosphere; sometimes the pollen of flowers; at others, irritating odors from animals. The removal of any one of these three factors is generally followed by a cessation of the disease. Improvement in the general health removes the neurotic factor; change of environment the irritating substance in the atmosphere; removal of the nasal obstruction relieves the third factor.

As regards nasal obstruction being a factor in the production of indigestion, we can only guess at the way in which this occurs. It may be the swallowing of large quantities of mucus or its disagreeable odor; it may be reflex irritation or the absorption of toxins from bacteria on an inflamed mucous membrane. My own experience has been that many cases of this disorder (my own among them) are relieved by being able to breathe freely through the nose the entire twenty-four hours.

I believe that the latest theory of gout and rheumatism is that they are produced by two factors: First, an underlying one, faulty metabolism, in which we include disorders of the digestive tract, with the production of substances circulating in the blood, such as urates and the like; second, an exciting cause, bacterial poisons introduced from without. The theory is that bacterial toxins break down the leucocytes into fibrin; this fibrin circulating in the blood is deposited where the circulation is the slowest, that is, in the serous membranes, and entangles in its meshes the products of faulty metabolism. These bacterial toxins do not always gain entrance through the respiratory tract. Instance the case of a man who came under my treatment seven years ago, when I was in general practice, who told me that he had had a three months' attack of gout every winter for eighteen successive years. He gave a history of gonorrhea twenty-five years before, and the resultant stricture was large enough to admit a urethal sound No. 23 French. Upon dilating this stricture he had a slight attack of gout which lasted twenty-four hours, but after its full dilatation up to 33, he has been entirely free from the disease ever since. As we know, a great deal of neuralgia is either gouty or rheumatic; so, what I have said about gout and rheumatism applies, to a great extent, to this disease also. I will give one case as an illustration:

A well-known New York City official was sent to me last October for deafness of the left ear. An examination showed, not an hypertrophied inferior turbinate, as is usual in these cases, but an hypertrophied middle turbinate, over which there was a persistent thick yellow discharge, with the odor of a dead dog. He informed me that people needed only one sense to know that he was in the vicinity, and I readily believed him. After removing a portion of the middle turbinate, I found an abscess directly above it, which dated back to an attack of influenza twenty years ago, ever since which time he had suffered from a severe pain over the lumbar muscles, which destroyed his night's rest, and which no treatment had relieved, although he had spent a small fortune trying to get rid of it. Eight days after the operation, with daily insufflation of an antiseptic powder, the pain in his back disappeared. Twice since then, on taking cold in his nose, the pain has returned coincident with the discharge from the old abscess, but antiseptics applied above the middle turbinate immediately relieved the pain on both occasions. In this case I believe that the pain in his back was produced by the toxins absorbed from the nasal abscess.

Neuralgia of the face is often caused by defective eye refraction or bad teeth. A great deal of it is only a symptom of frontal sinusitis or disease of the antrum of Highmore.

As regards the production of colds in the head, throat, or lungs, a partial vacuum means local congestion and a freer entrance for germs in these localities. Frequent colds cause a hyperemia and redness of the outside of the nose, and thus increase its size in some cases. Nothing is more distressing than a red nose, particularly for one who does not wish to be considered intemperate. I have in mind the case of a young man, an Italian, who was sent to me by his family physician, and who, being particularly temperate, even for one of his race, was much distressed because everywhere he went, people thought him a hard drinker. A double inferior turbinectomy, by diminishing the frequency of his attacks of rhinitis, restored his nose to its normal color and shape. A facial acne, which he had had for several years, coincidently disappeared, whether or not from the absence of toxins formerly absorbed from the nose and excreted through the skin of the face, I cannot say. The case seems to be suggestive, however, in view of the fact that we know almost nothing about the cause of facial acne.

As regards homeliness of face and figure: a stopped-up nose in infancy causes the child to breathe through the mouth, resulting in a lateral pressure on the upper dental and the palatal arches with the absence of the counterpressure of the tongue, and so a pushing forward of the upper front teeth in some cases; of the lower front teeth in others from frequent tonsillitis; and the resultant narrowing of the space between the two maxillas causes the so-called hatchet face. The habit of mouth breathing from the inhaled air being cold and dry results in more shallow breathing, and so

in an ugly contour of the chest, and in round shoulders.

Now, as regards the treatment of these conditions:

1. *Prophylactic*. I believe it is admitted by all competent observers that the bodies of most human beings uninterfered with from without, functionate normally, and that if our bodily functions are abnormal they are so from outside interference. The avenues of entrance for these unfavorable influences are either the skin or mucous membrane. For the former we have such examples as syphilis and some septicemias; for the latter such diseases as diphtheria, gonorrhea, and typhoid. The most frequent avenues of access are the nose and throat. Disinfect these twice a day, at the time that the teeth are brushed, and I believe we will avoid most of the diseases of childhood. I have in mind two instances of this; one, a case of measles in a three-room flat, where I had the mother disinfect the noses and throats of the other children, with the result that they did not contract the disease, and the other, a case of a friend who was visiting with his three-year-old son in a family where there was whooping-cough. He kept his child's nose and throat disinfected during his stay, and he was the only one of five children who escaped the disease.

Some time ago a doctor of this city called my attention to a case of cerebrospinal meniningitis which had begun with tonsillitis, and which to me seemed to have been infected by this means. My subsequent investigations have led me to believe that this is its usual mode of entrance, and also that of anterior poliomyelitis, which I believe to be this disease with its initial symptoms masked. I advocate unhesitatingly the spraying out of the nose and throat daily with an antiseptic for everyone. It is no more trouble than brushing the teeth, and I believe it to be much more important. I do this myself, and urge everyone that I know to do it.

As regards the treatment of these conditions after they are established, I advocate the removal of every nasal obstruction and the widening of every narrowed palatal arch by a competent orthodontist; and for the homeliness of figure, subsequent breathing exercises and dumbbell exercises. As the nasal obstruction is the cause of the palatal narrowing, it must first be removed before the palatal arch is widened, otherwise the latter will be impossible. By the removal of nasal obstruction I mean the excision of adenoids, polyps, and hypertrophied turbinates, and the correction of septal deflections.

Of nasal obstructions the most common is an hypertrophied condition of the inferior turbinated body. There can be no permanent relief of this condition without its partial excision. A cauterization of it, as practised by the Vienna school of specialists, is useless. For nine years I suffered with this condition and had numerous attacks of tonsillitis each year. I had spurs of the septum removed and the turbinates repeatedly cauterized by chromic acid or the electric cautery. At the end of this period I was actually worse than at the beginning. I was often temporarily relieved by the contraction of scar tissue following cauterization, but a subsequent cold again caused tumescence of the turbinates—my nose was again stopped up, and the former process had to be repeated. Seven years ago (at the end of nine years of fruitless treatment), I had two-thirds of the inferior turbinates removed with a saw, and barring two attacks of tonsillitis, have been perfectly well in that way ever since.

The removal of the inferior turbinates is attended by considerable hemorrhage on account of the large blood-vessels which they contain. The giving of twenty grains of potassium bromide and an equal amount of quinine beforehand, and the use of a spray of adrenalin at the time of the operation and for several hours afterwards, obviates this difficulty entirely. The operation may be done either with cocaine as a local anesthetic, or with any general anesthetic, preferably chloroform, as causing less dilatation of blood-vessels. I prefer local anesthesia, which is induced as follows:

First, a 4 per cent. cocaine spray. At the end of three minutes, a 20 per cent. solution of cocaine on a piece of cotton at the end of a nasal applicator inserted under the overhanging ramus of the inferior turbinate. At the end of a few minutes as much of the turbinate as is necessary can be painlessly removed with a Curtis nasal saw. My operation differs in one important respect from that of other specialists of the American school, in that I operate on both sides of the nose at the same sitting. My reason for this is that a great many patients, having one good nostril always remaining free, dread having the other side done on account of the cocaine reaction. I find in looking over the results of other men who do this work that a good proportion of their patients do not return to have the other side operated on, and so the work is only half done. I follow the method of Dr. Sharp in having the patient use the spray of adrenalin after the operation; rather than that of Dr. Griffin, who packs the nose tightly with cotton for twenty-four hours, which the patients find is accompanied with a great deal of pain.

Two-thirds of hypertrophied inferior turbinates, average size. A, side view; B, front view; C, cross section at center of A.

As the turbinate contains a plate of bone as thin as paper it does not subsequently grow again, and we have a permanent result. We hear all sorts and kinds of objections from the Vienna school to the removal of a portion of this body. We are informed that it has a function, namely, to warm and moisten the air that goes to the lungs, or that its removal will be followed by necrosis. As a matter of fact, when no air goes through the nose, none is warmed and moistened, and neither in my own case, in the three hundred operations that I have performed in private practice, nor in ten thousand in which the results are known to me, have there been any disagreeable results whatever. These objections are merely bogeys of the imagination. The real objection of the Vienna school is founded on their fear of hemorrhage, which I have shown can easily be avoided. I have here a few specimens which I will now show you. I ask you, can anyone breathe through a nostril which contains one of these hypertrophied bodies? The peculiarity of many of these patients is that they often breathe through the nose without apparent difficulty. The truth is that they are unable to get enough air by this means, and their attempts to do so make the partial vacuum which, I believe, is the cause of these conditions. Most of the deaf people who come to me, apparently have free nasal breathing, but partial removal

of the inferior turbinates results in increased, or in recent cases, perfect hearing. I have in mind the case of a man and his wife, acquaintances of mine. They have an equal amount of nasal obstruction. He frankly breathes through his mouth, and therefore has projecting front teeth, but his hearing is perfect. She believes that one should breathe through the nose whether this can be done easily or not, and she is almost stone deaf as a result, although her facial contour is perfect. In other words, given a nasal obstruction, if you breathe through the mouth continuously you will be liable to projecting front teeth, to inhale tubercle bacilli, or to asthma caused by cold dry air breathed through the mouth instead of being warmed and moistened by going through the nose. On the other hand, if you breathe through the nose you are liable to catarrhal deafness and sore throat as a result of the partial vacuum.

As regards treatment—I believe that in all of the conditions enumerated, free nasal breathing will probably be beneficial. In any event, it does one no harm to breathe through the nose always, and it is a source of great comfort. To quote a most observing woman of my acquaintance whose husband suffered with pulmonary tuberculosis for five years: "In consumption, I believe the nose is the whole thing. When my husband and I were in Denver, I noticed all the consumptives there breathed through their mouths." On the other hand, sometimes the results are quite surprising, as in the case of a young woman of twenty-eight who had been a sufferer from chronic rheumatism, and who has now for one year been entirely free from it after no other treatment except a double inferior turbinectomy.

I, myself, in addition to my catarrh, have had several attacks of pulmonary tuberculosis. The first at the age of seven, from which I recovered by being kept continuously in the open air. This occurred again at thirteen, and again at twenty-four. At the age of twenty-six I had a much more serious attack of it, and was confined to my bed with what was diagnosed as typhoid fever. At the end of three weeks, one afternoon I received an urgent call, and being unable to get another doctor, I dressed myself and walked half a mile to the patient's house, having at the time a mouth temperature of 102½°. On my return my temperature was normal. The following day, against the attending physician's advice, I acted as a witness in court, and that afternoon went to a neighboring park, where, overcome with dizziness, I had to lie down on one of the benches for some time before being able to sit up. However, my temperature remained normal that day and the next. I then visited my father at his country house about 400 feet above sea level, where I remained out of doors almost continuously. At the end of a week my typhoid fever (?) was so much improved that I returned to duty in Bellevue Hospital, spending all my spare moments playing tennis on the court there. Two years afterwards I had an inferior turbinectomy performed, and have never since been troubled with my lungs. Incidentally, I had one uncle die from this disease, and my father and another uncle have suffered from it from time to time. I have dwelt on my own case at some length because I wished to impress one point upon your minds, which is, *that you can arrest the progress of tuberculosis much more rapidly and make its recurrence less likely if you at once give your patient a nose which is absolutely free the entire twenty-four hours.* I desire to emphasize the fact that the virulence of this disease has very much diminished in the last fifty years, for the mortality from it had lessened quite as much in the first half of that period before our increased understanding of it and its proper treatment, as it has in the last half since we have been treating it according to more modern methods. We find that these methods postpone the fatal results rather than abolish them, unless the underlying cause, namely, nasal obstruction, is permanently relieved.

I will now give a few more instances of results in this class of diseases:

Hay Fever.—I have relieved three cases of this disease (the only ones I have had) by an inferior turbinectomy—one of eight and the other of ten years' standing. I have relieved countless cases of catarrhal deafness, one of them sent to me by Dr. Nelson, but I will mention the results of only two of the most striking. The first is the case of a woman of thirty, whose hearing last summer, after ten years of treatment by some of the foremost specialists in this country, was so bad that she was learning the deaf and dumb language. She can now sit in my waiting room and hear everything said in an ordinary conversational tone. The other case is that of a woman thirty-four years old, who had been growing more and more deaf since the removal of the uterus and appendages a year ago, during which time she had been under treatment for her deafness at one of our largest clinics for four months, and the balance of the time with a well-known specialist. At the time of her first visit to me she could hear a loud Ansonia watch tick only one inch away from the left ear and two inches from the right. At the end of one week, after a double inferior turbinectomy and Politzer inflation, she could hear the same watch tick ten feet from either ear, and this improvement has been permanent. This was, of course, a case of functional deafness, and as such, easily relieved by this treatment. The digestion of every person whom I have operated on has been greatly improved. Every case of frontal sinusitis has been cured, and colds have been made much less frequent and disagreeable from the fact that the nose has been always open.

As regards homeliness of voice: The matter is so simple that every medical man understands it perfectly. The frequency of catarrh in this country causes the nasal voice which has so often been referred to by foreigners, and is, of course, due to our sudden changes of temperature. It is analagous to the stoppage of the upper part of an organ pipe. The improvement in the voice of a singer is sometimes quite wonderful after the nose is made perfectly free.

I wish to mention the results in cases of chronic otorrhea. I have done a double inferior turbinectomy in many of these cases, and have cured every one of them without the mastoid operation. In addition to this, I often had to give antisyphilitic treatment, because syphilis, either inherited or acquired, is frequently an underlying cause. I believe many such cases would not have to be operated on repeatedly if the nasal obstructions were first removed.

My treatment of asthma consists in relieving all nasal obstructions and in following this up for one year with twenty grains of iodide of potassium in a whole glass of water, milk, or vichy, and one-twenty-fifth of a grain of arsenious acid after each meal. Every patient treated in this way has been permanently cured, and one of these had had asthma every day for fifteen years.

Before closing, I wish to give the results of treatment in one other disease—lobar pneumonia. In

the *Journal of the American Medical Association,* three or four years ago, Galbraith, a New Englander practising in Mexico, gave his results in the treatment of this disease at an altitude of 8,000 feet, where up to that time it had been invariably fatal. His treatment is two doses of one dram each of some saline laxative, one hour apart. With the second dose he gives a simple enema, and as soon as the bowels move he gives ninety grains of quinine either on the tongue or in capsules, to adults, and thirty grains to infants, following it with fifteen minims of tincture of chloride of iron every three hours in adults, and children in proportion. He treated seventy successive cases in this way without a death. I have treated three with definite recovery within two days, and I have had reported to me from among my friends three other cases; one of them observed by a doctor of this city. I herewith present a chart of one of my own cases. One peculiarity of it is that the patient gives no symptoms of cinchonism, the lungs apparently absorbing the entire dose. I believe that the perfect treatment of this disease has at last been found.

The New Amsterdam, Seventy-fifth St. and Amsterdam Ave.

THE INJURIOUS HABITS AND PRACTICES OF CHILDHOOD: THEIR DETECTION AND CORRECTION.

By KARL H. GOLDSTONE, M.D.,

Jersey City, N. J.

Physician to the Children's Clinic, Mount Sinai Hospital, New York, formerly attending physician out-patient department, Harlem Hospital.

Within recent years the trend of medical progress has been first on therapeutic lines, second on the detection by the use of vaccines of certain maladies which fail to present outward manifestations, and thirdly on bacteriological research.

If I may be allowed I would compare these advancements to the moral and religious missionary labors which are of two great classes: (*a*) Foreign missions, (*b*) domestic missions. The fields of progress that I have enumerated above can be said to represent foreign missions, in that they propagate thought in new climes, on foreign soil; we have been clamoring for some goal far from our own hearth. Hygiene, body susceptibility, environment, heredity, proper living, restraint—these are domestic missions. For these foreign missions, let us give thanks. They are the essentials of science. But nevertheless have we not neglected theoretically our own bodies, slighted our own predispositions, and above all failed to give enough credence to the value of two of the heaviest spokes in the wheel of medical septuary* namely, Etiology and Prophylaxis?

Superstition, the twin sister of idolatry and false dogmas, the subtle advance agent of ignorance, has, conjoined with neglect, been the forerunner of most of the functional neuroses of childhood, acquired first by practice, then by habit, lastly by the stunting of the higher intellectivities. As Holt succinctly puts it ("Diseases of Infancy," edition 3, page 700), "At this time apparently trivial causes are enough to produce quite profound nervous impressions because of the instability of the motor, sensory, and vasomotor nerves. Hygiene of the nervous system is of the utmost importance in infancy and childhood. A normal development can take place only in the midst of quiet and peaceful surroundings with plenty of time for rest and sleep. The conditions of modern life, especially in cities, are such that these laws are almost invariably violated, and the consequences of this are seen in the marked and steady increase in nervous diseases among children."

In order to comprehend fully these manifest truisms it becomes necessary to study the influences that affect or determine an individual's entity, and these are: (1) Forces exerted from within, and (2) forces acting from without, or in other words, habits exercised by the child and practices laid to the mother and which affect the child.

Masturbation.—Any act that produces undue excitement—psychical explosions—is conducive to harm. Especially so in the child with its unstable nerve centers and the nondevelopment of the voluntary centers of the brain. I am firmly convinced that the large number of the phenomena designated under the general term "nervousness" in early life, have their seat in the evolution of the psychical, physical, and reflex explosions produced in the act of masturbation, and that the general practitioner is rarely alert to the fact of its existence. The child is nervous, the mother adduces; the physician looks wise, seeks out chorea as the causative factor, and prescribes arsenic.

Those of us in public practice have had this fallacy brought to our notice time and again. By older children this habit is practised in secret, because they know that they are committing a wrong. But in infants, by careful observation and patient watching one can almost always have demonstrated the antics and physical manipulations which the infant passes through as being acts of self-abuse. They are not idle antics; they are the efforts of the baby to get its fingers into the genitals for the purpose of producing the pleasurable sensation the repetition of which gives rise to the habit, which in turn is the prodrome and incitor of a neurosis, usually stamped as "nervousness" and falsely attributed to one of the other common nervous disorders of childhood. I have observed infants as young as five months masturbating, and of the sexes the females practise this act much more frequently.

As predisposing causes are those which underlie most of the habits of childhood; these are: (1) Malnutrition, especially overfeeding and the abominable practice among the ignorant of giving whiskey and beer even to infants. (2) A highly neurotic constitution attributable always to heredity, mental and moral delinquency in the child as the results of vicious habits and traits in the parents, principally sexual perversions and alcoholism. As exciting causes are adherent prepuce in both sexes, gonorrheal vaginitis, eczema of the pudendum, and the presence in the rectum of the *Oxyuris vermicularis.*

Those who expect to find the infant always using the hands to masturbate will be disappointed. Infants and young children accomplish the act in the majority of cases by thigh friction and by assuming postures in which the genitals come into contact with some object, usually a chair, the edge of the bed, or a pillow. One child of eighteen months that I have in mind would stand on the first rung of a chair, bend over so that the genitals would come into contact with the edge of the chair and emit a peculiar groan or sigh, and sway from side to side. Another made use of the mother's knee. Masturbation produces such an undue nervous excitement that after the act is completed the child will break into a profuse perspiration with

*Etiology, pathology, symptoms, diagnosis, prognosis, prophylaxis, treatment.

suffused face, bewildered and tremulous, in short, evidences of high nervous tension. That chorea, hysteria, and epilepsy are among the sequelæ, few will doubt. Sachs ("Nervous Diseases of Children," page 539) is authority for the statement that dementia præcox and complete idiocy are the ultimate results of masturbation in children. Boys will teach the habits to others and in this way pollute and corrupt a whole school. Later on they practise pederasty, making use of boys and girls of their association. They do not get along with their studies, lose their power of concentration, and become easily excitable or depressed. And these are the precursors of the army of moral perverts that we see in our large cities.

Local signs in the female are hypertrophy of the clitoris and vaginitis; in the male balanitis and eversion of the lips of the meatus urinarius.

Masturbation is always a most difficult habit to break, especially in older children. In infants we can do a great deal to mitigate the habit and to eventually cure it. I must reiterate and with increased vehemence, that if the practitioner will learn to consider masturbation as an entity and to detect it early and correct it, he will come nearer to effecting a lasting cure; for a case that has gone on for a long period is a puzzle to the physician and an abomination to the child. The restraint that is needed is of two kinds, physical and moral. In children under three years the contrivance that is most successful consists of side splints attached with adhesive plaster to the thigh, the outer splint reaching from above the trochanter to below the knee, the inner from halfway down the thigh to below the knee. Other physical methods are tying the legs to the sides of the crib, and also tying the hands. Moral persuasion works well in young children. But in older ones more stringent methods are needed. The child's companions and surroundings should be looked into and his confidence obtained. While here, let it be said that great credit is due the society of Sanitary and Moral Prophylaxis of New York, and especially its founder, Dr. Prince A. Morrow, for the good work in enlightening the profession and the public and propagating the true dogmas of sex and sex hygiene, moral prophylaxis, the teaching of the young, and the total banishment of prudery. There is more reason for teaching school children the physiology and anatomy of sex than there is for enlightening them on the workings of the digestive organs, for the abuse of the former works greater havoc in children than neglect of any other of the functions of the body. Older children who masturbate should be sent from home if possible, given the benefit of good hygiene, fresh air, and away from books or studies, and treatment should be directed toward the general health. Local causes must be looked into and corrected; these are circumcision in boys and forcible separation of adherent prepuce or nymphæ in girls. Mild counterirritation to the clitoris is beneficial, as are also cold ablutions to the spine.

Habit Spasm.—Spasm independent of chorea is one of the neuroses of childhood, which have heredity as the main predisposing factor and bad training as a concomitant. Spasm is the *bête noir* of the Pediatrist, and like other of the habits of childhood is the culmination of uncorrected practices, and neglect on the part of the physician. I am ready to defend the statement that these spasms are at first always voluntary, and under the full control of the will; but by persistence they become firmly fixed and are then not in the category of habits and may be designated as pure neuroses like athetosis, which is uninfluenced by treatment. Habit spasm is very frequently the result of mimicry and manifests itself by facial grimaces, blinking, frowning, shrugging of the shoulders, and is often accompanied by a coarse tremor of the hands. I have never seen the spasm affect the lower extremities. The diaphragm in the cases that have gone on for a long time is thrown into spasm, as evidenced by a dry, hard cough, gasping, sudden, long-drawn inspirations, and hiccough. While at first these movements are infrequent, later they become almost continuous. Usually a certain set of muscles will be affected and this will last for quite a length of time. Then another set becomes involved, and so on. I have noted the fact that early in the case of these spasms the larger muscles and those more frequently used are affected. Later the smaller and less used muscles become spasmodic, such as the muscles that move the ear or the eyelids, and the small muscles around the nose.

Habit spasm is almost always confounded with chorea. But if the practitioner will keep in mind that chorea is a definite nervous disease characterized by irregular jerking unrhythmical movements not under the control of the will and intensified by efforts to suppress it and accompanied by loss of power in the muscles involved, mistakes in diagnosis will not occur. Besides, the duration confirms the diagnosis.

Almost the same rules of treatment apply to habit spasm as to masturbation. Early correction, mild and gentle admonition, and attention to the general health. These children should receive the benefit of fresh air, country life if possible, and above all should be taken away from school. Rachford says ("Neurotic Diseases of Children," page 403), "School life in my opinion brings to bear on the irritable nervous systems of neurotic children the etiological factors which are most important in the development of habit spasm." These are too early rising, stair climbing, long hours, and too strenuous study, improper attention to the bladder and bowels, confinement in stuffy rooms, anxiety over examinations, and overzealous and neurotic teachers. To repeat, when the habit becomes fixed, treatment is of no avail.

Sucking.—Lindner (*Jahrbuch für Kinderheilkunde*, Vol. 14, page 68) divides sucking into simple sucking and sucking with combinations. In the former the child makes use of some part of the body, as the thumb, fingers, toes, lips, or a blanket or part of the clothing; and most frequently, the "pacifier," a consideration which will be taken up later. In sucking with combinations, the sucking is accompanied by masturbation, or rubbing of the ears or anus, which affords a pleasurable sensation. Sometimes sucking is accompanied by acts which produce pain, as pulling of the hair and scratching of the skin. Sucking begins in infancy and if not corrected early, may go on to puberty, and infants who persist in the habit of sucking always become masturbators. Sucking, like other habits, becomes fixed and is then almost impossible to control. Besides the nervous factors, the sequelæ of sucking are, deformities of the fingers, lips, and teeth, and curvature of the spine. These deformities may be serious.

The advice given in the case of the other habits is equally applicable to sucking—early restraint, gentle admonition, and hygiene. Covering the hands with mittens is effectual, as is also the use of long sleeves which are pinned to the bed. The

same apparatus that I mentioned for masturbators answers for toe-suckers.

Pica (the eating of unwholesome and repulsive substances).—In the degree of danger to life and health that they entail, none of the habits I mention approximate dirt-eating; for this execrable habit may give rise to grave nutritional disorders and even cause death. Pica is a perverted instinct akin to animalism, and simulates what in the lower order of beings is self-preservation. In Jamaica and other of the West India islands, pica is so prevalent as to be classed as endemic. But we find dirt-eaters quite frequently in our own country, where the habit is analogous to sucking, masturbation, and habit spasm.

Ignorance, lack of proper training and supervision, bad hygiene, lack of sunshine, and improper and badly prepared food are among the causes, backed by heredity. Imitation and mimicry are the inciters of this habit, and according to Rachford, "propinquity and opportunity have much to do with the development of pica in infancy." Chalk-eating, a common practice amongst school children, frequently leads to pica.

The name explains itself; and the objects that these children devour includes almost every article that they may find—clay, sand, cinders, dirt, etc., are among the more common. Hundreds of instances are recorded by observers, all of them illustrating the fact that normal healthy children may form the habit, contrary to the earlier belief that it occurred only in idiotic and insane children. It is true that the habit usually ceases under mild restraint, at the age of three years, but only to be replaced by another, none the less pernicious habit, as spasm or masturbation. Hence the importance of early correction. Duke in the *Lancet,* 1884, reported the case of a child of five years who was brought to him for worms. By careful observation he discovered the fact that the child had been eating sand and mortar from the garden where he was allowed to play. The habit had been in progress for two years, during which time the child passed one hundred large round worms. The same author cites some instances in which death followed the ingestion of dirt, while in nearly all of the cases profound nutritional disturbances or severe anemia and emaciation followed.

Change of surroundings with a good nurse and proper dietary measures are of the greatest importance. Thomson (*Archives of Pediatrics,* April 1907) formulates the treatment of pica as follows: (1) Improve the general health; (2) treat the child's digestion; (3) keep the child away from the substances for which it has a craving; (4) change the child's surroundings; let him be happy and busy.

Nail-biting is a habit which is less pernicious and not so common as the others, but should be corrected early for the manifest reason of its being conducive to other habits. The child's finger nails should be kept short.

Head-banging.—Gee (St. Bartholomew's Hospital Reports, Vol. XXII, 1886, page 97) describes head banging as a habit in children between the ages of two and six, characterized by violent banging of the head against a pillow or other object, lasting for a few seconds, and alternating with swaying of the head and head rolling. It is akin to habit spasm. In some instances it seems to be the effort of the child to relieve pain of earache or neuralgia.

Spasmus Nutans.—While not included in the category of habits, it may not be amiss to state that a nodding movement of the head occurs in children as the result of mimicry. Thomson (*Scottish Medical and Surgical Journal,* July, 1900) believes in an intentional spasmus nutans. In my experience with these cases, I have failed to satisfy myself on this allegation.

Disorders of Sleep—Pavor Nocturnus.—According to the classification of J. A. Coutts (*American Journal of the Medical Sciences,* February, 1896) night terrors may be divided into two main types: (1) True night terrors due to the disturbances of the central nervous system; (2) nightmare or disturbances of sleep, the result of bad practices. Those of the first type cannot be considered here, as they belong to the true neuroses of organic nature, and are not under voluntary control. But I simply want to add that to my belief true pavor nocturnus is nothing more or less than nocturnal epilepsy. In the first class of cases, there is loss of sleep from the beginning: the child is restless and peevish, and, after rolling and tossing about, he falls into a light sleep, but soon wakes in a state of fright or excitement. Bad dreams are uncommon and the child remembers on the next day what has taken place the night before. These points distinguish it from true pavor nocturnus. The mind is clear and the child falls asleep again. The causes of this pseudoinsomnia are bad habits, such as rocking the child during sleep, night feeding and the consequent indigestion and colic. Lack of fresh air in the sleeping chamber and the presence of adenoid vegetations in the pharynx are among potent inciters. Again, infants much pampered, and which are taken up as soon as they cry, become poor sleepers.

Proper training is most important. The infant should under no circumstances be rocked. Cradles are as distressing to a child as a small boat in an open sea is to an adult. Regulation of meals and attention to the stools are not to be ignored. In older children, exciting stories should be avoided and reading and studying at night should be interdicted. While here let me put stress on the necessity of avoidance of overstrain in the schools. School hours should be regulated according to age. I would have for children between six and eight years of age two hours of study divided into two sessions. From nine to twelve years, four hours, and over thirteen full time. Girls evincing signs of the approach of the menses, should be kept from school until three months after puberty has been established; and last but very important, children should be put to bed at a definite hour.

Home Therapy.—Soothing syrups. From my experience in the past, I am led to the conclusion that the part that dentition plays as an etiological factor in causing disturbances in infants is nil. As Holt adduces "the physician who starts out with the idea that in infancy dentition may produce symptoms usually gets no further than this in his etiological investigations." And again, "probably in 95 per cent. of the cases in which symptoms are present they are due to some cause other than dentition." I purposely place dentition in this category, for it is for the relief of this fanciful trouble that soothing syrups are given. Some neighbor recommends Mrs. So and So's "dope" as good for teething, and the result is, if not death, a train of disturbances which deteriorate the health of the infant and render him particularly susceptible to disease.

Embrocations.—Among the ignorant a favorite remedy for colds is to rub over the chest some such thing as camphorated oil, vaseline, horse liniment,

tar, and other nasty preparations, which clog up the natural avenues of excretion in the skin, prevent proper radiation, and render the baby more liable to attacks of cold, just the antithesis of what these lotions are supposed to do. I decry the fact that many practitioners encourage this practice and even advise it.

Enuresis.—Those who have treated bed-wetting and have failed, as all of us have in a large percentage of cases, will welcome any light that may be thrown on this subject; and in my estimation Church's deductions are the best that have appeared in recent years. In the *Archives of Pediatrics* for September, 1906, he says: "Local conditions found in association with inability to control the outlet of the bladder, may furnish the inciting cause, but the underlying substratum of perverted innervation or incompetent innervation, is the field in which such inciting cause works, and only too frequently the correction of every local and mechanical state fails to relieve the enuresis. The fact that the condition is amenable to mental measures and in a high degree to suggestion, stamps its nervous and even its psychical character."

The Pacifier.—Of late years such competent observers as Kerley of New York and Cotton of Chicago have reached the conclusion that one of the most potent factors in the production of adenoids in children is the sucking of the pacifier. Hence I give this form of sucking extra space and consideration, because I believe it to be one of the most pernicious and harmful habits of infancy. This execrable habit is found among all classes of people. The good influence that it is supposed to exert, imaginary, as can be seen, is to quiet the child, stop its crying, take the place of feeding, and allay the symptoms of teething (?). The pacifier can be said to quiet the child only in the same sense as body sucking and masturbation quiet or rather satisfy the child, but only to be replaced by the reaction of a mental explosion, the result of high nervous tension. It takes the place of feeding only if one were to consider swallowing of dirt and germs as feeding. It cannot allay the pain of teething for the very evident reason that I adduced before—there are no symptoms of teething. The sucking of the pacifier produces in infants (1) the formation of adenoids by causing a congestion of the postpharyngeal wall, and consequent hypertrophy of the lymphoid tissue situated between the two Eustachian tubes and known as the pharyngeal tonsil; if adenoids are already present, they increase in size and extent for the very same reasons. (2) Deformities of the mouth and palate by the presence of adenoids whose growth it incites, and by the repeated twisting and distorting caused in sucking. Children who are subject to the habit have a high arched palate, diseased and deformed teeth, and thickened lips. (3) Colic and flatulence, by the sucking in of air. (4) Ulcerative stomatitis and sprue, by the sucking of dirty particles that always collect on the pacifier. (5) Hypertrophied tonsils, due to congestion as mentioned in adenoids.

In conclusion allow me to reiterate with increased emphasis the plea for early detection and correction of these habits of childhood; for the awakening of physicians to the great importance of hygiene in early life, to the recognition of the fact that a habit, though seemingly harmless in itself, may and usually does give rise to other and more pernicious habits to the detriment of the future mental and physical health of the child; for the inculcation of these doctrines in mothers and others who have the welfare of children at heart; and for the profound necessity of uprooting in very early life the maleficence and the curse of heredity, by inuring the child at an early age to the fastidiousness of good manners, kindliness, respect, personal cleanliness, and discipline.

279 York Street.

Primary and Secondary Spasmodic Paralysis; Origin and Treatment.—Maurice Faure, in a paper read before the ninth French Congress of Medicine, says that the type of primary contractures is represented by spasmodic paraplegia with little or no sensory and trophic troubles. The origin of the spasmodic condition is in the central lesion. The symptoms have rarely any tendency to regression. Often, on the contrary, they have a tendency to progress. In spite of the character of permanence and incurability of the cause of the spasm it may be overcome by treatment of a mechanical nature, the technique of which the author indicated. After some weeks or months of passive exercise and methodical movements the lower extremities become supple again. Since in these cases the motor loss of power is allied with the contracture, and the loss of the habit of movement, it is possible to reteach the patient voluntary motion at least partially as soon as the contractures are overcome. The type of secondary contractures is represented by hemiplegia. The appearance of these contractures constitutes a second stage in the evolution of the disease, and this stage coincides with the appearance of serious trophic disturbances. It has been for a long time believed that trophic troubles and contractures were allied with a central lesion of which they constituted (like primary flaccid paralysis) a necessary symptom. It has been seen, however, that some trophic symptoms, such as arthritis, were the result as much of modifications of nutrition resulting from immobility as from the central lesion. For contractures we may make a similar statement. Contractures do not appear in subjects that have been treated with passive movements from the beginning of the disease, neither do the arthritic troubles appear. When they have begun, methodical passive movements will lessen their severity. The hemiplegiac, his contractures removed, may relearn some voluntary movements; others return spontaneously. The best means of favoring their return is to prevent contractures and arthritis and the accompanying vicious attitudes. To sum up, methodical passive movements prevent the occurrence of contractures, and conquer them when they have taken place. Their use will enable the patient to avoid contractures, deformity, and ankyloses which are frequent complications, often irremediable, of hemiplegia and paraplegia. Passive movements followed by reeducation cause or hasten the return of voluntary motion.

Experimental Researches as to the Presence of Tubercle Bacilli in the Scales of Pityriasis Versicolor.—Michelangelo Cipolla says that some authors have endeavored to show that the tubercle bacillus is found in the scales of pityriasis versicolor, and that they are the cause of the disease. He gives the experiments made on several patients, after scrubbing the patches so as to remove all adherent bacilli, to find the germs in the patches of pityriasis versicolor. The results have been entirely negative, and the author considers it proved that the tubercle bacillus is not the cause of this skin disease.—*Giornale Internazionale delle Scienze Mediche.*

Smallpox and Pregnancy.—Queirol shows that the fatality of smallpox in pregnant women depends on the severity of the disease. All mothers and children die in the hemorrhagic variety. In the confluent form the position is serious, but in the discrete form many mothers and children survive. The question of the author is, what is the cause of the abortion. He admits that in the hemorrhagic form there are probably hemorrhages which separate the placenta from the uterine wall. In the other cases, he believes that it is the infection of the fetus with the disease, and its death that produces the abortion. He finds that there are no placental lesions or changes in the membranes, and that the fetus generally comes away whole. There are found germs in small numbers in the blood of the fetus. It is also certain that the infection is transmitted, because there are recorded cases in which the fetus was born marked with the scars of the disease. Mothers have nursed smallpox cases, having been immunized by vaccination, and have given birth to children marked with smallpox. Hence, we should seek by repeated revaccinations to immunize the pregnant mother and prevent abortion by obtaining a discrete form of the disease.—*Revue Française de Médecine et de Chirurgie.*

MEDICAL RECORD.

A Weekly Journal of Medicine and Surgery.

THOMAS L. STEDMAN, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 51 FIFTH AVENUE.

New York, June 20, 1908.

PRESIDENT-ELECT GORGAS.

IN the election to the Presidency of Col. William C. Gorgas, the American Medical Association has honored itself and given satisfaction to the medical profession of the entire country. For a number of years an unbroken succession of surgeons has presided over the meetings of the Association, and the humble practitioners of medicine who constitute the great mass of voiceless and voteless members of that organization had begun to thing there was honor only in the knife, and that honest work in the prevention and cure of disease was unworthy of recognition. The Chicago papers said that the election was brought about by a revolt against the domination of "the Chicago clique" in the Association, but whether so or not, the decisive vote of 90 to 29 showed that Dr. Gorgas was the choice of a large majority of the delegates, and there is no question that his election will receive the cordial approval of the profession of the country.

Dr. Gorgas was born in Mobile, in 1854, but New York can claim him as one of her medical sons, for he was graduated from the Bellevue Hospital Medical College in 1879, and served on the house staff of Bellevue Hospital during the year following his graduation. He was appointed assistant Surgeon in the Army in 1880, promoted Captain in 1885, and was made Surgeon, with the rank of Major, in 1898. His experience with yellow fever began in 1882, when he was Post Surgeon at Fort Brown, Texas, and himself suffered from the disease during the epidemic which prevailed at that post that year. During the Spanish War he served on the hospital ship Relief, and later was placed in charge of the yellow fever camp at Siboney, Cuba. His work there was interrupted by an attack of typhoid fever, but immediately after his recovery he was sent to Havana, to serve as Chief Surgeon of the Department and Sanitary Officer of the city. Although not a member of the Army Commission, he followed closely and sympathetically the work of Major Reed and his associates in demonstrating Finlay's theory of the agency of the mosquito in the spread of yellow fever, and when the work of the Commission was concluded he put its findings into practice with the result of freeing the city from the pest which had held it in its deadly grip for centuries. But he did more than this—he demonstrated to the world that the great scourge of the tropics could be eradicated, and that henceforth the presence of yellow fever in any city was to be regarded as a disgrace to the sanitary authorities. When this country undertook the completion of the Panama Canal, it was recognized that success in the undertaking was only possible through the suppression of disease, especially yellow fever and malaria, and that Gorgas was the man to accomplish this work. For a time he was hampered by the ignorant opposition of the Panama Commission, a fact which was revealed to the country by the "indiscretion" of Dr. C. A. L. Reed, who had been to the Isthmus, and unofficially told what he had seen there. Then Gorgas was made a member of the Commission, and given full power to effect sanitary reforms; and the work in Havana was repeated in Panama and Colon, with the inevitable result that now the Isthmus is safe for Northern workers, and the completion of the canal is assured.

For his service in ridding Havana of yellow fever, Dr. Gorgas was promoted Colonel and Assistant Surgeon-General of the Army by special act of Congress in 1903. This work, as well as that done in Panama, has been described by Colonel Gorgas and others in a number of articles published in the MEDICAL RECORD since 1901, and a most interesting chapter it is in the history of sanitary service. The President-elect of the American Medical Association is a man of few words but of great deeds, and, judged by what he has accomplished, he is far and away the foremost sanitarian of his day. He has conquered the disease which made tropical cities the graveyards of Northern men, and on the Isthmus of Panama he has also reduced the malaria mortality, so that it is no longer a menace to the man who observes proper precautions. The election to the Presidency of a man of such proved executive talent augurs well for the future of the American Medical Association.

OCCULT BLOOD TESTS.

SMALL amounts of blood in the stomach contents or feces are detected with difficulty as the red cells are quickly destroyed in the gastrointestinal tract, yet the recognition of the presence of traces of blood is often of extreme importance in diagnosis. In the *Centralblatt für die Grenzgebiete der Medizin und Chirurgie* for May 7, 1908, L. Isler reviews the entire literature regarding the various tests for occult blood, and comes to the conclusion that all the microchemical tests (Teichmann's, etc.) have the disadvantage that negative results do not mean an absence of occult blood. All observers agree that the extraction tests are the best, and of these the guaiac, aloin, and benzidin tests are most frequently used, the last mentioned being the best in that it is the most sensitive and the easiest to carry out. Isler considers the presence of occult blood in the feces of greater value than that in the gastric contents, as the stomach tube, which often causes bleeding, is not used, and as it is easier to exclude bleeding from the respiratory tract, mouth, pharynx, and nose. Meat, even when cooked, will give the blood reaction both in the gastric contents and in the feces, so that a positive test is of value only when the patient has not been given meat or meat products for from three to ten days.

Isler also discusses all publications concerning the conditions under which occult blood has been found. It is usually found in patients with ulcers or ulcerating carcinoma of the gastrointestinal tract,

and in patients with pyloric stenosis of benign or malignant origin when particles of meat may remain in the stomach for a long time and are then the cause of the positive test. When the gastrointestinal tract is engorged as a result of cardiac disease, occult blood is usually found. The test is of value in differentiating between gastric ulcer and gastric neuroses, also between gastric ulcer and cholelithiasis, it always being negative in neuroses and cholelithiasis. A positive test, good motility, and absence of free hydrochloric acid point toward a carcinoma of the stomach even though no tumor is palpable. Of course in all cases in which the test is to be of value it must be repeated frequently and always after all other sources of hemorrhage are excluded and after a patient has been abstaining from meat for three days or longer.

Isler's review leaves no doubt that repeated positive tests for occult blood, provided all sources of error can be excluded, point to a pathological condition, and that they may frequently be of value in the differential diagnosis of diseases of the digestive organs.

SOME PHASES OF THE OPHTHALMO-TUBERCULIN REACTION.

The medical journals still contain many articles giving the clinical experience of authors with the ophthalmo-tuberculin test of Calmette. At present the only conclusion that can be drawn from their perusal is that the reaction in question is of value as one point in the general clinical and laboratory picture leading to the diagnosis of tuberculosis. Its final significance can be established only by further observation, and the time has come when an agreement upon the technique to be used in eliciting the reaction is to be thought of in order that the results obtained by the different observers may be at all comparable.

Floyd and Howes (*Journal of Medical Research*, No. 4, Vol. XVII) state correctly that a positive test obtained with the weakest solution is of most value and recommend the use of two saline solutions of the alcoholic precipitate of tuberculin, of 0.33 per cent. and of 0.5 per cent. strength, respectively. The weaker tuberculin is to be first instilled into the left eye, and if no result is obtained, the right eye is to be used for testing with the stronger solution. A few points noticed by those authors in their work are of interest to others trying this diagnostic method. Advanced cases of tuberculosis and cases under treatment with injections of tuberculin often fail to give a positive reaction, while apparently normal persons who have for a long time been in close contact with tuberculous patients may react positively. The cases in the first category are explained by the antituberculin immunity produced by the injections and in advanced cases by the exhaustion of the body resistance to the toxin; of the apparently healthy cases that reacted it is to be assumed that foci of disease undiscoverable by clinical methods exist in them, which assumption is strengthened by the history of long exposure to infection given in these cases. The final conclusion of the authors is that the old method of using tuberculin is more accurate in cases where the general susceptibility to tuberculin is slight; the ophthalmo-reaction, however, possesses the great advantage of simplicity over the old method; moreover, it may be used in acute febrile conditions, where the presence of fever prevents the use of tuberculin subcutaneously.

In another publication (*Journal of Experimental Medicine*, No. 2, Vol. X) McCampbell and White give the results of applying the Calmette test to the diagnosis of tuberculosis in cattle. Calmette's tuberculin preparation produced no results, and a special tuberculin procured from the United States Department of Agriculture had to be employed. A quarter of a cubic centimeter of this was used, in full strength, and the characteristic reaction was obtained in a sufficient number of cases to show that the method will probably be of value. Findings parallel to those discussed above were again noticed: the previous use of tuberculin subcutaneously interfered with the ophthalmo-reaction and advanced cases reacted less intensely than incipient ones. The authors are continuing with their investigations, and promise to give further data in the near future. Such work will be followed with great interest. The question of bovine tuberculosis and its relation to the human disease is still a debatable one, and the observations of the ophthalmo-reaction in cattle with the use of various tuberculins may throw additional light upon this vexing problem.

Typhoid Bacilli in the Blood of Nontyphoid Patients.

The finding of typhoid bacilli in the blood of a patient suffering from some obscure symptoms leads naturally to the diagnosis of the disease as typhoid fever. That the conclusion, however, may be only partially correct seems to be shown by the experience of Busse, reported in the *Münchener medizinische Wochenschrift* of May 26, 1908. In two patients with atypical intestinal and toxic symptoms the bacteriological examination of the blood showed the presence of typhoid bacilli, and thus led to the diagnosis of typhoid fever. The autopsy, however, disclosed the existence of miliary tuberculosis with many intestinal ulcers as the principal disease and the probable cause of death. Moreover, other findings spoke against the assumption that the tuberculosis was merely a complication, a terminal infection of a typhoid fever patient. The Widal reaction was negative during life, the intestinal ulcers and the mesenteric lymph nodes were tuberculous in nature, the spleen showed no characteristic changes of typhoid fever, and in one case, indeed, it contained tubercles. No history of a previous typhoid infection could be obtained, and the only plausible explanation was that the patients were chronic typhoid bacilli carriers, in whom the tuberculous disease gave the bacilli a chance to penetrate into the tissues and into the blood. In two other cases, one of chronic tuberculosis, and one of acute lobar pneumonia, typhoid bacilli were found in the blood in the absence of any clinical picture of typhoid fever. Busse's conclusion, of course, is that the presence of typhoid bacilli in the blood is not a positive sign of typhoid fever. This finding is extremely interesting, but disappointing to the clinician, for it seems that even a positive blood culture does not always clear up an obscure case of infectious disease.

Relief of Pain Following a Laparotomy.

Every surgeon comes to realize the frequency with which postoperative symptoms appear after laparotomies and the difficulty of treating them. As these symptoms are usually explained by the presence of adhesions, their prophylaxis has consisted in rest to the bowels after the operation, and their therapy in various procedures designed to break up the adhesions, among them massage, high irrigations, hydrotherapy, etc. M. Jerusalem (*Münchener medizinische Wochenschrift*, May 26, 1908) has tried Bier's hyperemic treatment for this troublesome condition; he uses a large suction bell, applying it over the cicatrix for twenty to thirty minutes, every two or three days. In over twenty cases the results were surprisingly good and very rapidly attained, in comparison with older methods of therapy. Experiments on the cadaver showed that the effect of the suction was not limited to the abdominal walls, for the intestines were likewise lifted up and made part of the tissues that filled the mouth of the bell. However that may be in the living person, the technique of this treatment is so simple that it ought to be widely tried in suitable cases. If the author's results are corroborated, it will prove a boon both to the patient and to the weary surgeon, whose successful operation is often marred by the obstinate persistence of postoperative symptoms.

Fluids in Nephritis.

Physicians differ as yet in reference to the advisability of allowing much fluid in the diet of nephritics. Oertel, and after him v. Noorden, have especially recommended the reduction of fluids in order to save as much as possible the overworked heart of nephritis; Krehl, Romberg, and others, on the other hand, deny any harmful result of an abundant supply of fluid in such cases. H. Strauss, writing in the *Berliner klinische Wochenschrift* for May 25, 1908, shares the views of the latter authors, believing that the normal adaptation processes of the organism are perfectly capable of preventing the overfilling of the blood-vessels, which might result in additional burden to the heart. Indeed, Strauss thinks that the fluid may serve a useful purpose in diluting the poisons that develop in the body during nephritis, and that may lead to the clinical picture of uremia. Large quantities of fluid, however, must not be given at once, but rather, much fluid should be administered in small portions throughout the day. If dropsy is present, the salt-free diet offers a much better chance of controlling it than the diminution of fluid. While the latter may be also practised in the usual cases, it is distinctly contraindicated when uremia is threatening; toxemia then is a greater danger than dropsy, and water ought to be freely given.

News of the Week.

A Psychiatric Clinic at the Johns Hopkins.—Mr. Henry Phipps has given to the Johns Hopkins Hospital funds for the erection and equipment of a psychiatric clinic, to be administered as a part of the hospital. A four-story building will be erected on the hospital grounds to accommodate sixty ward patients, together with rooms for private patients, laboratories, etc. In addition, Mr. Phipps will provide for the maintenance of a medical and nursing staff, including salaries for a professor of psychiatry and assistants, and other expenses, for a period of ten years. The amount of the sum to be appropriated for this purpose is not stated, but it is understood to exceed half a million dollars. In his letter to Dr. Welch, announcing his gift, Mr. Phipps says that it is his desire that in the admission of patients to the hospital preference should be given to applicants from Baltimore and from those cities with which his life and work have been closely associated —Pittsburg, Philadelphia, and New York. About a year ago Mr. Phipps gave $30,000 to the Johns Hopkins for a tuberculosis hospital. He also established the Tuberculosis Institute in Philadelphia, and three years ago gave $1,000,000, to be taken in charge by a commission and used to provide model tenement houses for the workingmen of New York.

Public Health in the Republican Platform.—The following is the very thin plank in the platform adopted by the Republican Convention in Chicago relating to the Government control of public health: "We indorse the movement designed to secure the organization of all existing national public health agencies into a single national health department, and favor such legislation as will effect this purpose."

Pure Milk Laws.—The recommendations of the Milk Commission appointed by Mayor McClellan last year have been adopted by the New York Board of Health in formulating new regulations to govern the city's milk supply. The rules provide that all milk containers shall bear a label or tag stating the location of the creamery or dairy from which they have been shipped and the date of the shipment; and that skim milk may be brought into the city, to be used for manufacturing purposes only, provided that the milk be for sale only in cans holding forty quarts, which shall be colored bright blue and bear the words "skimmed milk." The pasteurization of milk is to be carried out only under a permit from the Board; the milk, after being pasteurized, must be at once cooled and placed in sealed containers, which must be plainly labeled, giving the date and hour of pasteurization, the degree of heat to which the milk has been subjected, and the time of the process. Milk may be marketed also under the two grades, "selected" and "guaranteed." "Selected" milk must be from herds free from any disease of the udder or clinical signs of tuberculosis, must contain not more than 60,000 germs per c.c. in winter, nor more than 100,000 per c.c. in summer, and be delivered to the consumer only in sealed bottles labeled with the date of the earliest milking the product of which forms part of the contents, and within thirty-six hours after the milking. For guaranteed milk the minimum requirements are that the herd shall contain only cows which have not reacted to tuberculin; that the milk shall not contain more than 30,000 germs per c.c. when delivered to the consumer, and that it shall be delivered only in sealed bottles, plainly labeled, within thirty-six hours after milking.

Pasteurized Milk in Dublin.—Through the generosity of an American, Mr. Nathan Straus, a laboratory for pasteurizing milk was opened on May 29 in the City of Dublin, to be operated under the direction of the Women's National Health Association. At a meeting held in the Mansion House, the residence of the Lord Mayor of London, on that evening, Dr. Arthur Randolph Green of New York delivered a lecture on the efficacy of pasteurization in reducing the infant death rate. The movement has been widely indorsed in Ireland, and the Lord

Lieutenant has become interested, as well as the Lord Mayor and other prominent persons.

Canine Vagrants.—The recent hydrophobia scare in New York has called forth the statement that there are 150,000 homeless dogs in that city, and this, in spite of the fact that the Society for the Prevention of Cruelty to Animals reports that it takes to its shelters every day from 275 to 300 dogs and cats, nearly all of which, being unclaimed, are asphyxiated. During the past four months it seized 10,500 animals, mostly dogs. As has been suggested, this number of homeless dogs, while perhaps not too large for the City of Constantinople, where the dogs constitute the only street cleaning department in evidence, is entirely too great for New York, where official scavengers are employed.

Bombay Medical Congress.—It is announced that a medical congress, having special reference to tropical diseases and sanitation as applicable to India, will be held at Bombay in February, 1909. The session will extend over four days, and the scientific work will be divided between six sections. Among the subjects to be discussed will be plague, typhoid fever, relapsing fever, tropical diarrheas, differential diagnosis of the various types of malarial fever, dysentery, the pathological conditions dependent upon invasion of the Leishman-Donovan body, the part played by parasitic insects (other than fleas and mosquitos) in the dissemination of diseases peculiar to the tropics, the clinical and pathological effects of snake venom; beriberi, elephantiasis, mycetoma, leprosy, cholera, tropical surgery, and sanitation applicable to India. The General Secretary of the Congress is Lieut.-Col. W. E. Jennings, I.M.S., care Messrs. King, King & Co., Fort, Bombay, India.

The Plague in Caracas.—Several cases of bubonic plague have occurred in various parts of Caracas, indicating that the city is widely contaminated. Owing to the proclamation by President Castro that Venezuela is free from the plague, all sanitary precautions were abandoned, and, in consequence, an extensive epidemic is feared. The President himself remains in the interior of the country, at a safe distance from Caracas and La Guayra.

The Academy Library.—The following are extracts from the rules governing the use of the library of the New York Academy of Medicine by others than members of the academy:

By-Law XIII. Section 7. Candidates for fellowship, after announcement by the Committee on Admission, may be granted the privileges of the library, on the payment of a fee of $20 a calendar year or pro rata in advance. The amount so paid in a given calendar year shall be deducted from the candidate's admission fee if he be elected to Fellowship in a calendar year for which the fee was paid.

Section 8. Any person approved by the Library Committee and by the Council, may become an annual subscriber on such conditions as the Council may impose. Annual subscribers shall be entitled to a card giving the privileges of the library, good for one year from the date of their acceptance.

Section 10. The privilege of consulting the library, but not taking out books, may be granted for one month, when authorized by a card signed by the Executive Librarian or his representative, on written request by the applicant, to accredited representatives of Fellows of the Academy on application by the latter. No one shall be introduced under the provision of this section more than once in six months, except by special permission of the Council.

Section 15. The library shall be open to the public from 9 A.M. to 2 P.M. Fellows and persons included in Sections 7, 8, and 10 shall have access to the library from 9 A.M. to 10:30 P.M.

The fee of annual subscribers is now fixed at $20 a year.

"Suggestion" versus Miracles.—In a lecture on the miracles of Lourdes, recently, the Abbé Coubé distinguished between functional and organic disease, limiting the power of "suggestion" to the former, while stating that 650 cases of organic disease, chiefly cancer and tuberculosis, had been completely cured at the shrine.

Nurses Help Hospital.—Because of a lack of funds at St. Mark's Hospital, New York, and an insufficient response to an appeal sent out some time ago, the twenty-five nurses of the institution, graduates and training school pupils, have offered their salaries for the next three months to help the hospital over the hard times. Six thousand dollars is needed. In addition to its ward work, St. Mark's has a large out-patient service. It has also, since 1890, given out 32,955 free meals to hungry persons applying at the hospital.

Eye Tests for Chauffeurs.—The Marceilles Medical Society, believing that many automobile accidents are due to defective vision, has strongly recommended to the French Government that no chauffeur be granted a driver's license without first undergoing an eyesight test similar to the one employed for locomotive drivers.

Dinner to Dr. Martin.—Dr. August Martin of Berlin was the guest of honor at a dinner given on June 10 at the Hotel Astor, New York, by about fifty American physicians. Speeches were made by Drs. Clement Cleveland, Howard A. Kelly, Edwin B. Cragin, and B. H. Wells. Dr. Martin was present at the meetings of the American Medical Association at Chicago, and of the American Gynecological Association at Philadelphia recently.

Summer School at St. Louis.—For the first time in its history, the medical department of the St. Louis University has opened a summer school, which is to be continued during a six weeks' session. The school is elated over the fact that in the examinations for internes for the city hospitals twenty-one of the thirty-two appointments were given to its graduates.

Raising Standard at Cornell.—In his address to the graduates of the Cornell Medical College at the tenth commencement, on June 10, President Schurman of the university announced that, beginning with this year, only those holding the degree of B.A. or B.S. would be eligible for admission to the college. While foreseeing a diminution in numbers, he looked forward to securing much higher quality. In any event, he said, the Cornell Medical College was meant for the training, not of the average candidates, but of those characterized by marked mental endowments and good liberal education. The graduating class numbered fifty-seven, of whom one was a woman.

Long Island College Hospital.—The dean of the college, on June 9, conferred the degree of Doctor of Medicine on eighty-four graduates, sixty-two of whom have received hospital appointments.

Commencement Exercises.—The annual commencement exercises of the medical department of the University of Illinois (College of Physicians and Surgeons) were held June 9. Dr. Rudolph Matas of New Orleans delivered the doctorate address.

New Hospital for South Chicago.—The President of the South Chicago Hospital Association was

authorized at a recent meeting to advertise for bids for the construction of a building at a cost of $40,000.

New Hospital Stone Laid.—The Harlem Eye, Ear, and Throat Infirmary, having outgrown its present quarters, the cornerstone of a new building at Lexington avenue and One Hundred and Twenty-seventh street, New York, was laid on June 13 by Bishop Greer. The building will consist of two stories and a basement, and will cost $25,000. The first floor is to be used for offices and operating-room, and the second for wards. The institution was founded in 1881.

Strict Rules for Hospitals.—The City Council of Chicago recently passed the ordinance of Health Commissioner Evans, making more stringent the regulations governing hospitals. The ordinance creates an Advisory Board, consisting of the Commissioner of Health, the Fire Marshal, and the Commissioner of Buildings, whose duty it shall be to pass on the plans for a hospital. Maternity hospitals are defined so rigidly as to put out of business the numerous fake institutions now masquerading under this classification. All hospitals in the future will be required to make daily reports of the cases they receive. The license fee is fixed at $100 a year, but those institutions treating 10 per cent. of their cases free may obtain a refund of the license money. The penalty for violations is from $25 to $200 for each offense.

The New York Dispensary.—After an existence of nearly 118 years, the New York Dispensary, on June 8, moved from its quarters on Centre street to its new home at 180 Grand street. The Wickham Diet Kitchen, which has been maintained at the same place by the New York Diet Kitchen Association, moved with it. The old building is being torn down to make way for subway improvements.

Damages on Account of X-Ray Burns.—A man in Chicago has been awarded damages to the extent of $10,000 against the Lakeside Hospital, for burns which he suffered while submitting to *x*-ray treatment.

Tuberculosis Campaign.—The Department of Health of New York has instituted a series of stereopticon lectures, to be given in the public parks of the city as a part of its plan of education in the war against tuberculosis. The work is under the direction of Dr. John S. Billings, Jr.

Koch at Leper Colony.—In the course of his trip around the world, Prof. Robert Koch has made a visit to the famous leper settlement on the Island of Molokai, the scene of Father Damien's labors. A thorough inspection of the buildings and of the conditions of the lepers was made.

Recognition of Osteopaths.—The Appellate Division of the Supreme Court of Brooklyn has sustained the decision recognizing osteopathy as a regular school of medicine in the proceedings brought against the Board of Health because of its refusal to accept a death certificate signed by an osteopath. The case will probably be carried to the Court of Appeals.

Dr. L. Webster Fox, Professor of Opthalmology in the Medico-Chirurgical College, Philadelphia, has received from Dickinson College the honorary degree of Doctor of Laws.

Consolidation of Edinburgh Medical Journals.—The *Scottish Medical and Surgical Journal*, which was founded a little over ten years ago as a protest against nonprofessional control of the old established *Edinburgh Medical Journal*, has become merged with its rival, which continues under its old name.

Vital Statistics of Pennsylvania.—According to the first annual report of the Commissioner of Health of the State of Pennsylvania, covering the period from June, 1905, to December, 1906, there were 10,780 deaths due to tuberculosis. Pneumonia and other diseases of the respiratory system constitute a good second, while violence, with 10,180 deaths, forms the third largest group. Seven hundred and eighty deaths were due to suicide, and seven of these occurred in persons under fifteen years of age, the youngest being twelve years old. Homicide shows a steady tendency to increase, not alone in Pennsylvania, but throughout the entire registration area of the United States. Cholera infantum is fourth in the list of the causes of deaths, one child in forty under the age of two years dying from this disorder. There is reason to believe that births are not reported with the same degree of accuracy as deaths, but, according to the statistics, the annual increase in population is about 50,000. The evidence, however, goes to show that in Pennsylvania, in common with other parts of the United States, and with certain foreign countries, there has been a gradual reduction in the birth rate. The average age at which women were married in Pennsylvania during the year 1906 was 24.5, while 32.2 per cent. of first born children occurred in women more than twenty-five years old. Under liberal use of antitoxin, which was supplied gratuitously by the State to impecunious persons, the mortality from diphtheria was reduced from 40 per cent. to about 11 per cent.

New Medical Society.—In order to bring the women physicians of Colorado into closer fellowship, the Women's Colorado State Medical Society has been formed, and articles of incorporation filed. Membership is open only to women who are already members of the State Medical Society.

Ontario Medical Association.—At the annual meeting of this society, held on May 27, at Hamilton, Ontario, the following officers were elected for the ensuing year: *President*, Dr. H. J. Hamilton, Toronto; *First Vice-President*, Dr. R. R. Wallace, Hamilton; *Second Vice-President*, Dr. A. Dalton Smith, Mitchell; *Third Vice-President*, Dr. A. M. MacCaul, Collingwood; *Fourth Vice-President*, Dr. George Field, Cobourg; *General Secretary*, Dr. E. Stanley Ryerson, Toronto; *Assistant Secretary*, Dr. J. E. Davey, Hamilton; *Treasurer*, Dr. J. H. Mullins, Hamilton.

The Upper Cumberland (Tenn.) Medical Society held its annual meeting on May 26 and 27. The following officers were elected: *President*, Dr. B. S. Rhea, Bon Air; *Vice-Presidents*, Dr. J. T. Moon, Algood; Dr. T. J. Potter, Smithville, and Dr. W. M. Breeing, Livingston; *Secretary*, Dr. V. L. Lewis, Crossville; *Treasurer*, Dr. R. E. Lee Smith.

Belknap County (N. H.) Medical Society.—At the annual meeting of the Belknap County Medical Society, held on June 1, the following officers were elected: *President*, Dr. A. J. Lafrance; *Vice-President*, Dr. E. P. Hodgdon; *Secretary*, Dr. A. H. Harriman; *Treasurer*, Dr. T. B. Cook.

The Medical Society of the Utah State University, at the meeting held on May 25, elected the following officers for the coming year: *President*, E. L. Peterson; *Vice-President*, W. W. Beck; *Secretary and Treasurer*, Lourrine Miles; *Executive Committee*, A. L. Leonard and F. D. Stewart.

The Late Dr. Farrington.—At a meeting of the

Harlem Medical Association, held June 3, 1908, the following minutes and resolutions were adopted:

Whereas, Death has removed from among us a former President, and one of the founders of the Association, Dr. Joseph Oakley Farrington, unusually long and favorably known and highly respected by us; therefore, be it

Resolved, That we deeply regret the loss the Association has sustained in the death of its Second President, who enjoyed the fruits of his profession for over half a century.

Resolved, That the Association extends its sympathy to the family of the deceased, and that a copy of these resolutions be spread in full upon the minutes of this Association; that they be forwarded to his family, and also be sent for publication to the medical journals of this city.

(Signed) Joseph E. Lumbard, M.D.,
Michael C. O'Brien, M.D.,
Edmund L. Cocks, M.D.,
Ex-Presidents of the Harlem Medical Assn.

Obituary Notes.—Dr. William Hazard Sherman of Yonkers, N. Y., died on June 11, after a long illness, at the age of forty-nine years. Dr. Sherman was a graduate of the College of Physicians and Surgeons, New York, in the class of 1884, an alumnus of the Presbyterian and St. Luke's Hospitals, and an attending surgeon to St. John's Riverside Hospital, Yonkers.

Dr. George La Breche Smith of New York (Laval, 1890) died at his home on June 13, of gastritis.

Dr. Walter Hunn Nardin of Anderson, S. C., died on May 30, at the age of seventy-one years. Dr. Nardin was graduated from New York University in 1860, and had practised in Anderson from his graduation until two years ago. During the war he served as Assistant Surgeon in the Confederate Army. He was the founder of the Anderson Hospital, and at one time was President of the State Medical Society, and a member of the State Board of Health.

Dr. Jacob E. Schadle of St. Paul, Minn., died on May 29, following a paralytic stroke a short time ago. He was in his sixtieth year. Dr. Schadle was a graduate of Jefferson Medical College, 1881, and an authority on diseases of the throat and nose, occupying the position of professor of laryngology and rhinology in the College of Medicine of the University of Minnesota. He had accepted an invitation to speak before the International Medical Congress at Budapest in 1909, on the etiology and treatment of hay fever, a subject in which he had been deeply interested.

Dr. William H. Christie of Omaha, Neb., died on May 28, at the age of sixty-four years. Dr. Christie was a veteran of the Civil War. He was graduated from the Rush Medical College in 1868, and for twenty years had held the chair of materia medica and therapeutics in the Medical College of the University of Nebraska, but was forced to resign in 1907, owing to failing health.

Dr. James Coe Culbertson of Cincinnati, Ohio, died at his home on June 4, from arteriosclerosis, at the age of sixty-seven years. Dr. Culbertson was a graduate of the Bellevue Hospital Medical College in the class of 1865, having served during the war first as private and hospital steward, and later as assistant surgeon. From 1891 to 1893 he was editor of the *Journal of the American Medical Association*, and since 1893 professor of the principles and practice of medicine in the Cincinnati College of Medicine and Surgery. He was for many years editor of the Cincinnati *Lancet-Clinic*.

Dr. Robert Watts, Jr., of New York died at his home on June 8, of chronic kidney disease, at the age of forty-two years. Dr. Watts was graduated from the College of Physicians and Surgeons in 1893, and served as interne at Bellevue for two years. He was assistant attending physician at St. Mary's Hospital for Children at the time of his death.

Dr. Arthur A. Barrows of Hackensack, N. J., died on June 7, after being stricken with apoplexy in a Broadway subway train. He was sixty-eight years old, and was a graduate of the College of Physicians and Surgeons in the class of 1870.

Dr. L. B. Martin, one of the pioneer physicians of Iowa, died at his home in Des Moines on May 28, at the age of seventy-six years.

Dr. Winfield S. Colby of Cadiallac, Mich., died at his home on May 27, from tuberculosis, at the age of 31. He was a graduate of the Northwestern University in 1905.

Dr. Daniel M. Hurley of Norwood, Mass., died on May 31, after an illness of five months from Bright's disease, at the age of 44 years. He was graduated from Bellevue Hospital Medical College in the class of 1894.

Correspondence.

OUR LONDON LETTER.

(From Our Special Correspondent.)

GENERAL MEDICAL COUNCIL — MEDICAL SOCIETY'S CONVERSAZIONE AND ORATION—AFTER EFFECTS OF INJURIES—SURGICAL TREATMENT OF SCIATICA—OBITUARY.

London, May 29, 1908.

The General Medical Council met for its eighty-seventh session on Tuesday when the President, Dr. Donald McAlister, delivered his address. He stated that the difficulties in the way of reciprocity with the Province of Quebec had been removed by the spontaneous action of the local authorities. He learned that the War Office was prepared to grant Quebec graduates the same facilities for entering the army medical service as were enjoyed by Nova Scotia graduates and it was hoped the other provinces would consider the question from a national point of view. The President further referred to the difficulty of obtaining legislation to restrain unqualified practice and other evils affecting the profession. The executive committee brought up a report on reciprocity with Quebec which was approved by the Council, as stated in the President's address. The effect will be that the degrees of McGill and Laval Universities will be recognized here under the conditions prescribed in the medical act.

On Wednesday there was a rather unusual event, bordering on the comic but very well illustrating respect for law. Dr. McAlister having resigned his position of representative of Cambridge University had been appointed to the corresponding post for Glasgow University. The legal advisers of the Council considered resignation of the Cambridge seat vacated the presidential chair. With mutual compliments between himself and his colleagues he accordingly resigned the presidency and was immediately reelected.

The financial position of the Council has improved considerably and there is a surplus, although further expense has been incurred for the convenience of the press. Councillors have always seemed anxious to have their speeches reported at length, though when we consider the true function of the Council and its powerlessness to enforce its recommendations, it rather resembles a debating society than a legislative body.

The conversazione and annual oration of the Medical Society of London took place on the 18th inst. As I have already reported, the Fothergillian gold medal was on this occasion formally handed to Sir. A. Wright. After this the oration was delivered by Mr. Clinton Dent, who managed to infuse interest into a subject seldom discussed—viz.: The after-effects of injuries. The effects of railway injuries are indeed, as he said, often enough argued in the law courts, but the later consequences do not always follow the course predicted by experts. Even men engaged in hospital practice might not realize the importance of some cases. A simple fracture of the leg, especially if both bones were broken, would serve as an illustration

of this point. The patient might be seen on admission, during treatment and once or twice afterwards. Later on it might be found that the results were not so good as had been anticipated and the patient might not be able to resume his former employment. Under the recent legislation employers might be reluctant to take the risk of further accident and the workman who had received compensation might find that the sum awarded him was not the benefit he at first thought. Mr. Dent was of opinion that the early fixation in plaster, for a time thought sufficient for sound union, might delay restoration longer than other methods. From the wage-earner's point of view a broken leg was very serious. It kept him from following his employment for some six months, even if his work was not very exacting, and if he should break down after beginning he would come to be regarded as a damaged person and as such would certainly find great difficulty in obtaining even light employment. The orator thought that the attitude of hospitals to such injuries was changing and those in charge considered them from an educational point of view. He acknowledged that simple fractures usually excited little interest, though they were by no means neglected. Still surgeons perhaps supervised them less closely than cases of greater clinical value. This is a point worth consideration and I can endorse and emphasize Mr. Dent's view. A man I know followed the surgeons pretty regularly as a student for about a year without having the chance of seeing a fracture put up or hearing any remarks beyond a question to the house surgeon as to the progress of a case from time to time. Of course cases were put up by the resident on arrival and little could be learned until clinical clerking or residing began. After discharge nothing more was heard of them. But to return to Mr. Dent's views. He observed that a fracture involving the ankle joint would in almost every instance gravely affect the wage-earning capacity of a working man. He also referred to injury to the head, quoting the time-honored maxim that no such accident is "too trivial to be despised nor too serious to be despaired of." Everyone accepts this, but too often in apparently trivial cases the lesson is enforced by practical neglect of its wisdom. Again everyone recognizes the value, in fact the essential necessity of rest. It was agreed that rest should be protracted, but it did not appear to be sufficiently recognized that it should be prolonged in proportion to the responsibility attached to the patient's occupation and to his normal mental capacity for bearing the same.

The treatment of sciatica is so often unsatisfactory and when severe the sufferings of the victim so acute that it is small wonder physicians were disposed long since to hand over the cases to their surgical confrères. But stretching of the nerve, proposed more than thirty years ago and tried in numerous cases, has been disappointing. Another has been introduced by Dr. J. Crawford Renton, who gave an account of it to the surgical section of the Royal Society of Medicine on the 12th inst. A medical man who had had his nerve previously stretched with only slight benefit consulted Dr. Renton in 1895. He suggested that the nerve might be again exposed and thoroughly examined. The patient being a medical man could judge for himself and having suffered much begged Dr. Renton to expose the nerve and at the same time to extend his exploration to the popliteal nerves. Accordingly, Dr. Renton carried out the suggestion, exposing the sciatic by the usual incision. It was surrounded by adhesions extending up to the sciatic notch; one was one and one-half inches in length and breadth and extended from the nerve to the ischial region. This was divided with scissors and its attachment to the nerve cut away. Others were removed by stripping from the notch to the middle of the thigh. The external and internal popliteal nerves were also exposed and found to be normal. The patient made an excellent recovery and was working and bicycling in a month. He has continued well up to the present time —thirteen years. Dr. Renton said it was evident that stretching the nerve, even to the extent of raising the patient from the operating table, would have been useless in this case. He has since operated on thirty-two cases with benefit to all and they all remain well. He is very careful not to stretch the nerve more than absolutely necessary to completely remove all the adhesions. He thinks the best cases for the operation are those in which pain is absent when the patient is at rest but comes on when an attempt to walk is made. In these he has observed after subsidence of the acute symptoms, absence of tenderness on pressure along the line of the nerve. In reply to remarks by members Dr. Renton said there was no trouble of reformation of adhesions, if the thick ones were cut away and the others stripped off. He admitted there was also a future for electricity in many cases.

Dept. Surg.-Gen. H. R. L. Veale, M.D., died on the 22nd inst. at the age of 76. The deceased officer was a graduate of Edinburgh University, 1853. He entered the army in 1855 and retired in 1883; he saw service in the Indian Mutiny, 1857-8, and was severely wounded at the relief of Lucknow. He also served in the Egyptian Expedition of 1882. He was for a time Assistant Professor of Military Medicine at Netley and author of the "Notation Case Book" and "Bombay Medical Code." He contributed to the *Army Medical Report* on the "Fevers of Cyprus, Malta and Gibraltar," 1879, and on "Palpitation in Soldiers," 1880, as well as various communications to the Journals.

Dr. F. Rutherfurd Russell, Surgeon to the Royal Surrey Hospital, died on the 10th inst. after a short illness, aged 55. Educated at Edinburgh, he graduated, M.B., C.M., 1878, and proceeded to M.D. 1880.

Dr. F. J. Turnbull, of Kelso, was seized with an apoplectic attack when visiting a patient and died the next day, 10th inst. He was Surg.-Lt.-Col. in the Scottish Border Volunteers and a Lt.-Col. in the Medical Reserve.

Another death from apoplexy is that of Dr. J. W. Carpenter, of Goudhurst, Kent, who was seized while gardening on the 14th inst. and died before professional aid arrived. He was 79 years of age, took the double qualification in 1859 and M.D., St. And., 1862.

Dr. David Thompson, J. P., died on Wednesday, æt. 76 He was for nineteen years coroner for Cornwall and had served as Mayor of Launceston, of which borough he was a Justice of the Peace, as well as of the county. He had also been an active volunteer and a Brigade-Surgeon-Colonel.

OUR LETTER FROM THE PHILIPPINES.

(From Our Special Correspondent.)

HUMAN TRYPANOSOMIASIS—NEW OPIUM LAW—ENFORCEMENT OF THE PURE FOOD LAW—PRESERVATIVES OF BUTTER IN THE TROPICS—ABSENCE OF CHOLERA—ARTESIAN WELL SUPPLIES IN THE PHILIPPINES.

MANILA, P. I., April 2, 1908.

THE case of human trypanosomiasis which was reported at the last annual meeting of the Philippine Islands Medical Association by Mr. F. H. Willyoung, has been the object of considerable research both on the part of the Bureau of Health and of the Bureau of Science, but so far these efforts have not yet been rewarded with success. It will perhaps be remembered that the slide with the trypanosomes was obtained from some blood specimens which were taken for the purpose of ascertaining whether lepra bacilli were present in certain persons who were suspected of being afflicted with leprosy. From a number of such persons additional slides were taken, which were not examined until some days later at the main laboratory, and unfortunately in the transmission of the slides, the identification marks had become obliterated, so that it could not be definitely ascertained from whom the specimen came. By a process of exclusion, however, it was thought that the slide in question came from one of a number of persons who resided in the province of Albay and who were afflicted with elephantiasis. All these patients have now been reexamined with the exception of one, and they have all proved negative for trypanosomes. The one who was not examined died several weeks before the microscopist again arrived upon the scene, and it is, of course, not known whether this was the person from whom the specimen in question was taken. That the disease, however, is not prevalent in that section of the islands would seem apparent from the fact that large numbers of blood examinations were made of the residents of that district, and so far no trypanosomes have been encountered. The particular slide which contains the trypanosomes is in the possession of the Bureau of Science, and was exhibited at the Philippine Islands Medical Association, and seen by many persons who were familiar with the organism, and they all concurred in the diagnosis of the specimen.

The opium law which was enacted by the United States Congress and which has for its object the complete abolition of the use of opium in the Philippine Islands except for strictly medicinal or scientific purposes, became effective March 1, 1908. During the past year this law was put into force gradually by a system of taxes which increased almost from month to month until the sale of the drug was prohibited. It was hoped that in this way the opium habitués would themselves be compelled to reduce the amounts which they used. In addition to the foregoing, the government made arrangements to treat any person free of charge and pay

their transportation to and from the hospital who desired to be relieved of the habit. Up to the present time 233 patients of this kind have come under observation, and of these 186 have been discharged as cured. So far as it is possible to ascertain, no great hardships were caused by the withdrawal of the drug. Whether conditions are as favorable as surface indications would seem to show is, of course, not known yet, because there may have been large quantities of the drug brought into the islands before the law went into effect, and the great likelihood of smuggling taking place must also always be taken into consideration.

In the treatment of the patients at San Lazaro Hospital, it has been the experience that those who smoke opium give up the habit with apparent ease, while those who take it by mouth have somewhat more difficulty. Those who have been using it hypodermically suffer the most upon being deprived of the drug, and a much longer time is required to effect a cure in their cases. The ordinary opium smoker seems to be able to be cured in less than a month, while a much longer period is necessary in the case of the opium eater, and at least sixty days are required for the hypodermic user.

Considerable difficulty is still being encountered by the officials in the islands in enforcing the pure food and drugs act, particularly with regard to the foodstuffs imported from the United States. This may in part be due to the fact that on account of the Federal pure food law being rigidly enforced in the home country, many of the manufacturers found themselves with large quantities of foodstuffs on hand which could not be passed under the federal inspection, and the same were then sent to the Philippine Islands with the hope that the law would not be so rigidly enforced here. Considerable difficulty has also been experienced in the enforcement of the law with regard to preservatives in butter. Practically all butter used in the Philippine Islands is imported from Australia, and Australian packers claim that the same cannot be shipped in tropical climates unless it contains preservatives, while the Department of Agriculture of the United States holds that preservatives are not necessary. Experience with the shipments of butter which have been received during the last three months, which contain no preservatives, would seem to indicate that the contention of the Department of Agriculture of the United States is correct.

Cholera has again almost completely disappeared from the Philippine Islands, only a few sporadic cases still being encountered from time to time in the provinces, but there have been no cases in the city of Manila during the past two weeks. The northward extension of the disease appears to have been effectually checked by the sanitary inspectors of the Bureau of Health, who were sent to points north of those which were infected, and on account of being on the ground when the first case made its appearance, by prompt isolation and disinfection, many towns were, no doubt, saved from invasion.

This anticipatory system of combating cholera seems to be much more successful than any land quarantine which can be instituted, and does not give rise to so much opposition, and the cooperation of the inhabitants is much more easily obtained. From a study of the subject made by the Director of Health, it appears that cholera is endemic in the City of Manila and that it exists in the sewer system, and possibly at times in the water system, and is frequently conveyed by roaches and other vermin. It would seem that just as soon as the new sewer system and the new water system are completed, the disappearance of cholera from the Philippine Islands should result.

The plan of putting in artesian wells throughout the islands, which has been so actively agitated by the Bureau of Health for the past three years, seems to have taken firm root, and scarcely a day goes by now but that some municipality petitions the central government for aid to enable them to bore a well, or in cases where their funds permit, they are proceeding themselves with the work. The effect on the mortality of many of the municipalities has already been most striking. In some towns in the province of Pampanga, which have artesian water, it has been noted that the death rate dropped from 40 to 28 per thousand. If the use of artesian wells throughout the islands should become general, it probably will do more for the improvement of the public health than any one other plan which could be carried out. It will probably do much toward eliminating the intestinal parasites which are now the direct or indirect cause of so many of the diseases peculiar to, or especially prevalent in, the Philippines.

THE FIRST INTERNATIONAL CONGRESS OF LARYNGOLOGISTS.

(From Our Special Correspondent.)

DEATH OF SCHRÖTTER—RELATION OF LARYNGOLOGY AND RHINOLOGY TO GENERAL MEDICINE—TUBERCULOSIS OF THE LARYNX AMONG THE ANCIENTS—RELATION OF DISEASES OF THE NOSE TO THOSE OF THE EYES—TREATMENT OF TUBERCULOSIS OF THE UPPER AIR-PASSAGES—SEA AIR FOR LARYNGEAL TUBERCULOSIS—LARYNGOLOGY IN GENERAL DIAGNOSIS.

VIENNA, May 4, 1908.

THE first international congress of laryngologists, in connection with which there occurred a celebration in the memory of the founders of laryngology, Türck and Czermak, took place in Vienna on the 21st to the 25th of April, 1908. Seven hundred participants in the deliberations had gathered from all countries of the world and assisted in making the congress a memorable event in the history of laryngology.

The news of a tragical event, the sudden death of Professor Schrötter, interrupted the proceedings on the second day of the meeting. Only one day before his end Schrötter delivered an eloquent address in memory of Türck and Czermak, and that evening he entertained many representatives of science in his hospitable home. He was born in Graz in the year 1837 and received his education at the University of Vienna, where he became the best known assistant of Skoda. He was made privat-dozent of laryngology in the year 1867, and after the death of Oppolzer he took charge of the latter's clinic.

During his work as assistant he was busy with laryngological problems; in 1866 he published cases of internal extirpation of the larynx; in 1876 he described a new method of treating laryngeal and tracheal stenoses by the use of modeled bougies, which represented a great step forward in the technique of laryngology, being found even now in the armamentarium of most laryngologists. Later he published the first case of endolaryngeal operation for the removal of a sarcoma of the trachea. Among his important publications are found the chapters on the diseases of the heart in Ziemssen's Handbook, the description of a new method of dealing with echinococcus cysts, the first account of the occurrence of leprosy and of pemphigus in the larynx, his "Textbook of the Diseases of the Larynx," articles dealing with rhinoscleroma, disease of the pericardium, and laryngeal perichrondritis. He had also contributed the article on the "Diseases of the Blood-vessels" in the handbook of Nothnagel. In the year 1883 he raised his voice in favor of climatological treatment of tuberculosis, and has ever since been very active in the study and practice of sanitary science and the fight for the control of tuberculosis. The erection of the large sanatorium for the treatment of tuberculosis at Alland, near Vienna, is due to his efforts in this direction. With his death the last clinician of the second remarkable period of the Vienna medical school has passed away.

In addition to the scientific deliberations the Congress enjoyed many social events, among them a banquet in the City Hall and a reception by the Mayor of the town.

Professor Fränkel of Berlin delivered a paper on "Laryngology and Rhinology Considered from the Standpoint of General Medicine." He said that the inductive method of reasoning has gained ground in medicine as in science in general. He considered that the laryngoscopy with ophthalmoscopy were the most important steps in freeing medicine from the groping in the dark which it has done for many scores of years. At least, in the first ten years after the discovery of laryngoscopy more was done to uncover the mysteries of the pathology of the larynx than in the four thousand years that preceded. Not only have local disturbances of the larynx been cleared up by this wonderful addition to our technique, but the changes observed in the larynx have proved to be of the greatest importance in the diagnosis and the treatment of general diseases. The picture seen on the laryngological examination helped in many instances in the diagnosis of such important conditions as tuberculosis, syphilis, leprosy, and cancer; moreover, the study of the changes observed in the larynx in consequence of nervous disease has become a most important aid to the neurologists in the practice of their special branch of medicine. The introduction of the method of illuminating the larynx for the purposes of diagnosis and treatment stimulated the application of the same method to the study of other neighboring and distant cavities of the human body. At present the whole respiratory

tract from the nose to the bronchi is directly accessible to the eye of the physician, and this accessibility has resulted in great progress in the diagnosis and the treatment of disease. Frankel further paid tribute to the work of Zuckerkandel in adding to our general knowledge of this portion of the human anatomy, and to the work of Czermak in developing the therapy of the diseases involving the larynx. He said that operative technique entered upon a new era when in the year 1884 cocaine was introduced into practice, again by two Vienna physicians, Koller and Jellinek. Frankel then gave a vivid picture of the methods used in Vienna in the teaching of this specialty of medical practice and theory, and added that many of the devices used are worthy of imitation elsewhere. It is to be regretted, he added, that the methods of teaching laryngology are little uniform in the various institutions of learning, and the tendency still exists to include this branch in the study of otology. It is not to be forgotten that these two have little in common in many respects; even in the common ground of the nasal passages the otologists have different aims and speak a different dialect from the laryngologists. To unite these two branches in teaching and in practice were to produce a branch of medicine that could hardly be considered as a separate and well-defined specialty.

Dr. R. Imhofer of Prague spoke on "The Knowledge of Tuberculosis of the Larynx in Greek and Roman Times." Hippocrates appears to be the first in whose works we find knowledge of tuberculosis of the larynx. He describes a form of consumption in which the voice remains clear, and differentiates from this another type of the disease in which the voice suffers because of the formation of abscesses in the upper air passages. He pictures the peculiar sensation of itching, the bad odor from the mouth and the cough quite accurately, and adds that in the later stages of the disease fever appears and carries away the patient. The treatment he advises for this condition is very rational, though it is limited to purely dietetic and hygienic measures; he recommends the use of asses' milk, stay in the open air, etc. Celsus has also written about the formation of ulcers in the air passages. The other Greek and Roman authors knew only the symptom-complex of "angina," under which name all the serious diseases of the pharynx and larynx, accompanied with disturbances of respiration and of deglutition, were gathered. Galen had introduced a new conception of these affections. He speaks directly of a disease of the larynx which begins with the formation of ulcers, and passing over into the lungs results in general consumption and the death of the patient. He makes the diagnosis of this affection on the existence of pain in the larynx, the expectoration of masses of detritus and of pieces of cartilage. His method of treatment is worthy of attention. He believes that it is possible to introduce fluid medicines into the larynx by placing them in the mouth and then lying upon the back. Only a short time ago Heryng of Warsaw has recommended a similar method and has called it "laryngeal gargling." This forms but another example of the well-known truth that many a modern method of treatment is but an imitation of old and forgotten methods of the ancients.

Professor Glück of Berlin spoke on the results of operations and the methods used in cases of tuberculosis and neoplasm of the larynx observed in his clinic. He gave abundant statistics of his results and communicated the methods which have been so successful that the mortality in uncomplicated cases was zero, in complicated cases dropped down to 9 per cent. in some groups, and in no group was higher than 13 per cent. He then demonstrated five patients who were operated upon nine months to ten years previously. Four had suffered from neoplastic disease and one from tuberculosis. All patients were cured and spoke in a distinct voice, although they had been subjected to partial or complete removal of the larynx and in some cases of the neighboring anatomical structures. The patients were capable of continuing their occupations, and the results attained could therefore be considered perfectly satisfactory.

Professor A. Onodi of Budapest read a paper entitled "The Relation of the Diseases of the Nose and the Nasopharynx to the Diseases of the Eye." He considered the great practical importance of the therapy of eyesight disturbances dependent upon nasal conditions, and the methods to be used in the prevention of blindness of nasal origin. He spoke of his morphological studies which showed the close connection between the optic nerves and the posterior accessory cavities of the nose, and thus cleared up the reasons for the occurrence of the disease of the eyes in connection with nasal disturbances. Onodi called attention to the brilliant results attained by the conservative and by the operative treatment, and contrasted with these the cases of lost eyesight caused by negligence in treating the accessory cavities of the nose or by late operative interference. He further discussed the complicated question involved in the occurrence of disturbances of eyesight on the opposite side or on both sides when the nasal involvement is unilateral. He also touched upon the cases in which blindness followed the operative interference with the accessory nasal cavities of one side. He thinks that his morphological discoveries explain such accidents without necessitating any forced assumptions. The same findings may explain the occurrence of eyesight disturbances after the cleaning out of the posterior accessory cavities, such as have been observed in one published case. He then spoke of the possible injuries to the muscles of the eyes which operative interference with the posterior nasal space can occasion. After he had thus stated his views of the causal relations between the diseases of the eyes, the disturbances of the eyesight, and the intranasal conditions, Onodi expressed the hope that common work of the ophthalmologists and rhinologists, as well as clinical and pathological study of selected cases, will serve completely to clear up the important subject considered in his paper. In conclusion the speaker demonstrated very instructive preparations illustrating the close relationship between the optic nerves and the posterior nasal cavities.

Dr. Mahn of Paris demonstrated a self-retaining tongue depressor which could be used in the treatment of children in the examinations required in internal medicine, as well as in operative procedures of general surgery and of rhinolaryngology.

Dr. Gleitsmann of New York presented a paper on the "Treatment of Tuberculosis of the Upper Air Passages." The treatment of tuberculosis of the upper air passages has shown great progress in recent times, partly because of the appearance of new methods, partly because cases for various special treatment were more carefully selected. However, the great number of the means of treatment described in the literature continue to give evidence of the fact that no generally adopted methods exist; indeed, with the exception of a few laryngologists that have adopted one and the same method of treatment, the statement made by the author in a lecture before the New York Academy of Medicine in the year 1904 that no two laryngologists deal with such cases in a similar manner still holds true. Gleitsmann then spoke very fully on the tuberculosis of the nose, of the nasal accessory cavities, of the nasopharynx, and of the larynx. He said that it is self-evident that the well-known methods of dietetic, climatological, and hygienic treatment are not to be neglected in such diseases, especially as many of the patients were suffering from pulmonary tuberculosis as well as from the local disease. Surgical measures, the use of lactic acid, and galvanocautery will ever retain their sphere of usefulness, the latter being especially acceptable at the present time. Among the newer methods of treatment Holländer's cauterization with hot air, the various kinds of light treatment, such as Finsen's light, sunlight, with or without fluorescent additions, are to be mentioned in the front rank. It may be hoped, too, that further experience with radium and with "*x*-rays" will increase their value in such conditions. The author had most success in his personal practice with surgical treatment, with the use of lactic acid and galvanocautery, and in selected cases with the employment of tuberculin.

Dr. Hennig spoke of the "Influence of the Shores of the North and Baltic Seas Upon Tuberculosis of the Upper Air Passages." The influence of these seashores upon the diseases of the upper air passages is extremely favorable. Especially valuable has proved to be a long stay in the resorts situated on these seas for such tuberculous patients as have previously suffered from anemia, chlorosis, or general weak condition of the muscular and the nervous systems. The Baltic Sea is in general better adapted for the treatment of cases of tuberculosis because its resorts are better shielded from wind, its coast is rich in forest lands, and the railroad communication with it is very convenient. The climatological treatment must in every case be combined with the proper balneological, hygienic, and dietic measures, while, of course, the use of drugs and of inhalations is not to be neglected. Extensive tuberculosis of the upper air passages in connection with advanced pulmonary and intestinal lesions forms a contraindication to residence at these seashore resorts.

Dr. Jörgen Möller of Copenhagen spoke on the mechanism of the production of the chest and the falsetto voice. He attempted with the help of the *x*-rays to determine the relative positions of the cricoid and the thyroid cartilages in the production of notes of various pitch. Such observations, he believes, are valuable in giving an idea of the function of the cricothyroid muscle.

Professor Lermoyez of Paris read a paper on "The Significance of Rhinological and Laryngological Examinations in General Diagnosis." He said that laryngoscopy saw the light of the world in Vienna in the year 1857. Türck at that time, after many experiments upon the cadaver, succeeded in constructing the very simple instrument which has enabled us to see the interior of the larynx in a living human subject. Türck did not know at the time that Manuel Garcia had previously succeeded in viewing the living interior of the larynx, namely, his own. The fact is that the famous singing master came upon the idea of illuminating the interior of his own larynx by means of a mirror and thus study the appearance of the vocal cords. Czermak made the discovery of Türck known to the great body of physicians. He delivered lectures on laryngology, improved the apparatus of Türck, first made use of artificial light instead of sunlight for the illumination of the picture reflected by the mirror, and further completed the examination by introducing rhinoscopy, that is, the viewing of the nasopharynx from the throat. Thanks to the work of these two Austrian physicians, the pathology of the upper air passages could show progress similar to the advance made in the study of the diseases of the lungs after the discovery of auscultation. Very soon laryngoscopical examination found application in the technique of surgical procedures; Lewin and Bruns used it in their work and they succeeded with the use of this method in diagnosing and in curing a number of surgical conditions, especially neoplasms of the air passages, confronted with which internal medicine was helpless and the older surgical technique of very little use. The great chapter of laryngeal paralyses was scientifically opened by Traube in the year 1860. The laryngeal mirror proved to be a most important means of diagnosis in internal medicine; with the help of this mirror Traube succeeded in diagnosing the changes in the caliber of the thoracic aorta and of other large blood-vessels of the chest and neck. H. Gerhardt and Türck described the symptoms of the different varieties of laryngeal paralysis. Later this field of medical knowledge was very much enriched by the law formulated by Semon and the discovery of the nervous center for the larynx made by Krause. Since those days the larynx has become a very important organ in the diagnosis of disease, whenever affections of the skull, of the spinal cord, or of the thoracic cavity are concerned. The discovery of adenoid vegetations in the nasopharynx made by Wilhelm Meyer in 1867 was of extreme importance in helping us to understand the disturbances in the physical and mental development of the child. Then the examination of the nose very quickly became a valuable diagnostic measure in the hands of every physician, and the profession soon learned the great importance of diminished air space in the nose for the development of the lungs, of the heart, and the growth of the whole organism. In the year 1867 Ziem diagnosed the appearance of pus in the bony cavities situated in relation to the head and face and communicating with the nose. Further study of these conditions led us to understand thoroughly the accessory cavities of the nose, taught us the dangers lurking in the presence of such suppuration, and gave us means to combat their causes and consequences. The communication of Hack in the year 1881, which described the importance and the wide significance of the nasal reflexes, attracted much attention from the scientific world. As cocaine enabled us to operate painlessly for the various diseases in the nose, it seemed as if the "nosology of nosology," the study of the diseases of the nose, was destined to assume limitless importance. To-day we hold more conservative opinions in reference to the nasal reflexes, yet we must allow that disturbances in the nose may affect very distant organs, not alone by changing the course of the inspired current of air or diminishing its volume, but by forming the stimulus for the appearance of various nervous phenomena. Kirstein and Kilian finally directed us upon new paths, by constructing straight tube-shaped instruments, similar to the esophagoscope, and applying them to the study of the larynx and the larger bronchi. They thus invented the art of bronchoscopy, and already this youngest accomplishment and branch of laryngology has proved itself of immense value. With the help of bronchoscopy foreign bodies have been successfully removed from the larger air passages in cases where previously a dangerous and bloody operation would have been necessary. Doubtless bronchoscopy will cause a revolution in the present ideas of the pathology of the bronchi, which will compare with the changes produced by laryngoscopy in our conception of the morbid anatomy of the larynx.

Progress of Medical Science.

Boston Medical and Surgical Journal, June 4, 1908.

Atypical Cases of Tonsillar and Peritonsillar Inflammations with One Unusual Complication.—The unusual complication referred to by G. W. H. Merrill was an orbital involvment in which there occurred an ophthalmoplegia (external) with moderate exophthalmos. The retinal veins were large and full, and there were old and fresh patches of choroiditis. The case ran a long course, commencing with peritonsillar abscess, which ruptured, leaving a condition of general sepsis. Incision made later in the peritonsillar region was followed by severe bleeding. The main part of the paper refers to the author's experience in four cases, in which he dwells on the difficulty sometimes experienced in not finding pus when the usual incisions are made. Often there seems to be a gradual subsidence of the swelling and infection without there having been at any time a frank pus formation. The author collates the opinions of the various text-books on the treatment of infections of this region, and dwells on the difficulty of finding any definite pus pocket.

The Use of Silk Ligaments in Addition to Muscle and Tendon Transference in Infantile Paralysis.—R. Souther refers to the experiments of Lange, who showed that silk causes the formation of a tough tissue which surrounds it from origin to insertion. In other words, a strong intestinal tendon is produced throughout the length of the silk, which is substantial and tough. This new natural tendon not only reinforces the silk, but is sufficiently strong to take its place. The great fault of the old method of transplantation was that the transplanted muscles were inserted into paralyzed tendons which in time stretched. Then some groups of muscles are paralyzed while others remain strong, the point on which the transplanted muscle is to be inserted is selected, so that in doing its new work it will not only take the place of the paralyzed muscle, but overcome the position of the deformity. In this class the use of a silk ligament is advisable when the deformity is great, or when the transplanted muscle cannot reasonably be expected to correct the deformity, though it will take up the new motion. The author gives the histories of various cases in which this silk reinforcement has been tried, and gives directions for its special application on various sites. He notes the fact that in the use of silk ligaments in children one end at least should be attached to some soft tissue, such as tough fascia, a ligament, or the varied periosteum. It is not advisable to attach the ligament to a tendon or paralyzed muscle for a time, these will stretch and the position will be lost. In all such cases careful muscle training is a very important part of the after-treatment. Silk ligaments will stiffen the joint sufficiently to prevent lateral motion, but allow dorsal flexion, which is so necessary in walking. The method is for this reason preferable to arthrodesis even when the paralysis is pretty extensive. By preventing distortion, silk ligaments are extremely useful to supplement necessary transplantation. The newly transferred muscle takes up its work more readily and is relieved from other strain.

The Specific Action of Mercury in Syphilis.—H. G. Piffard quotes from his own writings of over thirty years ago to the effect that mercury removes symptoms and cures the disease, but sometimes does so slowly; while the iodide does not cure the disease, but removes certain symptoms with wonderful promptness. He also refers to certain experiments recently made in France in the inoculation of apes with syphilis. The ultimate aim of these researches was to find, if possible, some means whereby the effects of the inoculation could be prevented before the virus gained entrance to the general system. In this way they have apparently succeeded by the application of a mercurial ointment composed of one part of calomel and two parts of lanolin. This should be applied within twelve or eighteen hours of the time of inoculation, and when properly carried out general infection does not occur. In other words, the mercury applied locally destroys

the spirochete. Some of the French authors have put forward the view that mercury is even a greater specific against the local disease than against the general disease, and seem to think the idea a novel one, but over thirty years ago Piffard wrote as follows: "How does mercury cure the syphilides? Is it by some alteration of the constitution of the blood, and the consequent induction of nutritional changes, or is it by direct local action of the drug upon the lesion itself? The former is the more prevalent belief, but the latter, I think, is nearer the truth. Mercury cures the lesions by the particles being brought in direct contact with them, and *ceteris paribus*, the larger the quantity of mercury that can be made thus to act, the sooner the cure, provided the remedy be used in such a way as not to exhibit its own peculiar effects."

Multiple Conception.—After some statistics as to the frequency of multiple conception M. J. Karpeles relates the history of a case of triplets which he was called on to attend. The first child (all were girls) weighed five and a quarter pounds, the second five pounds, and the third four pounds. The patient had had triplets once before, and during her married life of six years a twin miscarriage in addition. In the present instance the first presentation was vertex, the second breech, and the third vertex. The placenta was very large, giving the appearance of three placentæ coalesced into one, with three cords and three distinct attachments to the placenta.

To What Extent Is Migraine Amenable to Treatment of the Eyes?—E. M. Alger gives detailed histories of ten cases. He notes that there are three ocular conditions which are conceivably concerned in attacks of migraine. First, and most important, over-use of the ciliary muscle in accommodation, which may exceptionally occur in normal eyes by reason of immoderate use, but is almost invariable in hyperopia and especially in astigmatism, since it is only by accommodation that clear vision is secured; second, come conditions in which binocular vision is impossible without undue strain of the extrinsic ocular muscles; and, third, the cerebral fatigue that comes from the constant interpretation of distorted or unequal retinal images, as in astigmatism and anisometropia. It can readily be seen that the relief of these conditions may often be a very complicated problem, an exact solution of which is sometimes impossible. In most people Nature herself has compensatory powers, and if we can bring the error within the limits of those powers we shall have given all the relief necessary. This is the reason why inexpert work is so often perfectly satisfactory to patients in ordinary conditions. But it must be remembered that in migraine and many other nervous conditions it is this very attempt at compensation that causes the trouble, and a much closer correction is called for. The one great defect in the evidence is the widespread failure of ocular therapeutics to afford relief, even when applied by men whose reputations are of the highest. This may be due to two causes, first, that the ocular treatment is seldom as patient and painstaking as it should be; and, second, because there may be cases in which eyestrain is not the chief cause and perhaps not a cause at all. On the other hand, there are many patients whose hereditary instability is so great that an explosion may occur from any one of several exciting causes. Suitable eye treatment might prevent some of these attacks, but could not possibly prevent them all. Other cases are pure eyestrain cases, and are completely relieved.

Journal of the American Medical Association, June 6, 1908.

Meaningless Diagnoses.—H. L. Wiel thinks the time has come for the medical profession to stop the use of certain ill-used but time-worn diagnoses, which mean nothing definite and are used merely to hide ignorance and satisfy the patient. Perhaps the most freely used of these is biliousness, which is no diagnosis at all; and he also mentions as falling into the same category typhoid pneumonia and typhoid malaria, ptomain poisoning, a frequently misused appellation, and gastric fever. There are many others; and, he asks, "Should not all conscientious physicians discard the use of these terms, and if there are none better to be found in the present terminology, why use terminology at all?" Rather than call things by false or meaningless names, let us call them by no names at all.

Varicocele.—F. K. Boland describes the anatomical conditions of varicocele, which he estimates exists in 10 per cent. of all men between the ages of 15 and 30. He credits unsatisfied sexual desire as a cause, and says no doubt a predisposition may be inherited. A varicocele without symptoms calls for no treatment, though it is sometimes necessary to operate to enable a candidate to pass a physical examination. Palliative measures will sometimes relieve, but operation is best and can be done under local anesthesia, though general anesthesia is better. The text-books say that excision of part of the scrotum is sometimes indicated; in the south, where the pendulous scrotum is so common, this is always indicated. Cures have been reported from this measure alone, and it certainly is one of the most important steps in the operation. If this is not done, the incision over the veins should be made just below the external abdominal ring, as advised by Dr. Bloodgood. Here the veins are fewer in number and the wound heals more readily than in the scrotum. In any operation the genital branch of the genitocrural nerve must not be injured, as it supplies the cremaster muscle. Boland prefers the open method of operating, in which two incisions are avoided and inspection of the testicle and tunica vaginalis is afforded, which in a large proportion of cases will reveal a hydrocele. The details are given; he removes a portion with a curved scrotal clamp, which is taken off and all bleeding points caught and tied with fine catgut. The varicose plexus is then exposed as far from the testicle as possible, and separated from the vas deferens with its artery and veins. The veins are firmly tied in two places, two inches apart, the lower ligature being tied first. The intervening section is then removed, care being taken to leave the stumps long enough to prevent slipping. He advises approximating the ends of the veins and stitching them together. The wound is closed longitudinally with silkworm sutures, the ends left long and tied together. Drainage is not usually necessary, rubber or oiled silk is used to avoid possible contamination by urine, and the dressing is held in place by a figure of eight bandage, which supports the testicles. After a few days it may be advisable to use a smaller dressing and a large suspensory bandage. The patient is kept in bed ten days, and a suspensory is worn only till the wound is well healed. Boland advises attention to details in the operation on account of the mental effect in neurotic patients.

Comatose Pernicious Malaria.—C. S. Neer describes this most frequent of the pernicious forms of malarial disease, and reports three cases, all fatal, occurring in Missouri. Its early diagnosis is important because of the effect of prompt treatment on the mortality. In the great majority of cases it is due to the estivoautumnal parasite, the development of coma depending on the number and toxicity of the parasites and especially on their localization in the brain. In temperate climates it usually occurs in the summer, in the tropics, at any season, and it usually occurs in those who have suffered for some time with malaria and have not received proper treatment. Its pathology in general is about that of other severe types of malaria, the most striking and characteristic lesion is the blocking of the cerebral capillaries by thrombi of malarial parasites, with secondary minute hemorrhages, and pigmentation. There is usually relaxation of the limbs, but there may also be twitchings of muscles, exaggerated deep reflexes, and even convulsions. Focal symptoms of brain disease may continue after the attack. With a previous history, diagnosis sometimes may be made from the symptoms alone, but if the patient is found comatose and history is lacking, a blood examination will be needed. The prognosis is always grave. Quinine should be given hypodermically. Craig thinks that 8 grains of the hydrochlorate, repeated until 24 grains have been injected, is enough in most cases, but admits that more may be required in very severe infections. The intravenous injection method may be used in the presence of very grave symptoms. Aside from the quinine, treatment must be symptomatic. Stimulants, especially strychnine, are often useful.

Experimental Deciduomata.—L. Loeb has followed up his investigations, which developed the fact that tumors of decidua-like tissue could be produced by incising the uterus in guinea-pigs. These tumors, he finds, attain their full growth in about ten or eleven days, and then become necrotic. Pregnancy may slightly prolong their life. Their development appears to depend on a certain condition in the sexual cycle of the animal. This occurs at a certain period after copulation, the optimum being between five and eight days, corresponding with the time when the uterus normally responds to the stimulation of the ovum with the formation of a decidua. Deciduomata were produced also at a certain period after heat, the optimum lying between four and nine days, without copulation. Experiments were undertaken to determine whether the contact of the ovum with the uterine mucosa caused the tendency to the formation of deciduomata; mechanical prevention of such contact showed that it was not necessary. Another series of experiments by extirpating, misplacing, or cauterizing the ovaries before making the incisions showed that their presence was essential to the formation of deciduomata; while some very minute formations appeared in one or two instances when the incisions were made very soon after the extirpation of the ovaries, this is explainable by assuming that a small portion of the substance secreted by the ovaries that causes the predisposition to deciduoma formation had

not all passed out of the circulation when the incisions were made. The fact that deciduoma could be produced in pieces of transplanted uterine tissue in the subcutaneous tissues proves that the ovaries do not act through the nervous connections, and an internal secretion has, therefore, to be invoked. It seems probable to Loeb, from his experiments, that the corpora lutea represent that part of the ovary which secretes this substance. This, however, will have to be decided by further experiments, which are in progress. The necrosis of the deciduomata probably occurs with the cessation of the secretion and disappearance of the corpora lutea. We are justified, he thinks, in concluding that this same secretion has a like significance for the formation of the placental decidua. In conclusion, Loeb calls attention to a certain analogy existing between these artificially produced deciduomata and a variety of multiple tumors that are limited to certain organs, as, for instance, multiple fibroneuromata, enchondromata, symmetrical lipomata, or adenomata of the intestinal mucosa; they might be called multiple systemic tumors. The deciduomata represent a type of new formations which he called "transitory tumors." If their causal secretion were continuously secreted by the ovaries they would not be transitory, but permanent new growths. In both these and the systemic tumors we have multiple benign tumors affecting a single organ. In the case of deciduomata, we now know on what it depends, and that, the causal secretion having been produced, indifferent stimuli, like traumatisms, suffice to produce the tumors. There are clinical observations indicating that certain tumors, sarcomata, for instance, have also been caused by traumatism, and he suggests the possibility of an antecedent "preparing" substance in such cases also. He discusses the bearings of the facts on the question of inoculability and transplantation of tumors.

The Lancet, May 30, 1908.

Acute and Transitory Dilatation of the Heart in an Infant.—E. L. Jones was called to see a child delivered fifteen hours previously with forceps, and weighing ten pounds. He found the child with a marked tonic spasm of the respiratory muscles and deep cyanosis. Compression of the chest with the head extended was followed by inspiration and the intense cyanosis was lessened. The heart did not seem enlarged and there was no murmur. In the course of one hour, when the spastic condition was so intense that respiration practically ceased, the heart was again examined, and, to the doctor's great surprise, the cardiac dullness was almost double its former breadth, extending an equal distance from the middle line on each side, while a loud systolic murmur was audible all over the front of the chest—most intense over the pulmonary valve. Chloroform, which had been sent for, had now arrived, and the child inhaled it, with the effect of relaxing the spasm. Color became normal. Examination of the heart now showed a normal dullness, and no murmur. The author ascribes the peculiar and temporary heart condition to the extreme dilatation of the right auricle and ventricle, causing regurgitation through the tricuspid valve, and there possibly was a leak through the foramen ovale, which was not entirely closed fifteen hours after birth. After recovery from the above attack the child went on in perfect health, and was reported normal when eight months old.

Treatment of Pulmonary Tuberculosis by a Postural Method.—Commenting on the value of having tuberculous patients bend forward over the edge of the bed, in the morning, to help clean their air passages of the night accumulation of secretion, A. T. Wise describes a special chair which he has devised, with an attachment which permits the patient to assume the prone or forward position without discomfort. It forms a double inclined plane (figured in the paper), and by this curvature of the body obviates excessive blood pressure in the cerebral vessels, as the lower extremities are not raised above the level of the head. The author believes that in addition to draining the air tubes by gravity the circulation is improved in the apices of the lung. The latter are now dependent, have a better blood supply, and some parts of the lung tissue become relieved of the weight of the heart. The semi-supine reclining attitude in vogue, adopted by votaries of the open-air cure and now universally carried out, where the patient lies on his back propped up with a pillow on a couch or reclining chair, is, of all customary sloping positions of the body, the most undesirable to further the easy evacuation of sputum from the lungs. Putting aside the effect on the pulmonary circulation, especially as regards the full blood supply to the cornered apices, this dorsal or supine slope of the thorax cannot but favor the extension of the disease from the apex of the lung to the back of the lower lobes by unintermitting gravitation. The common line of advance taken by the disease is actually seen to be in this direction. Better that the patient shifts his position from time to time than that any approach to the dorsal decubitus be maintained for a prolonged period of time. Even in those subjects who are taking gentle exercise the periods of called-for rest should not be forever spent on the weary backward incline. Some care must be exercised in selecting cases for postural treatment. Patients with a tendency to hemoptysis must use it continuously, as also those with fluid in the pleural cavity and those with a pronounced pneumonic type of tubercle.

British Medical Journal, May 30, 1908.

Primary Pneumococcic Peritonitis.—A. Smith reports two cases. Case 1 was that of a girl of eight years taken suddenly with abdominal symptoms. The general aspect, however, was that of a pneumonia, but examination of the chest was negative. The general condition continued the same for several days. One week later the abdomen was considerably distended. There had been somewhat of a crisis, but the fever rose again and was irregular; was essentially a pus temperature. Repeated explorations of the chest revealed nothing. Finally, at the end of two weeks, it was deemed advisable to open the abdomen, and great quantities of pus, pneumococcal in origin, were evacuated. Recovery was speedy and complete. Case 2 was that of a girl four years old with symptoms of acute appendicitis, but immediate operation was not deemed necessary. On the fourth day the appearance seemed typical of pneumonia, although all the pain complained of was abdominal, in the right inguinal region, with marked tenderness, resistance, and sense of fullness. On the eighth day of the attack, when she looked much better, the temperature was 99°. This certainly looked like a definite pneumonic crisis, but there were no further physical signs of pneumonia to be elicited on examination of the chest and the abdominal symptoms and signs persisted. The temperature rose again the same night; it continued to be irregular and the abdomen increased in size and fluid formed. A surgeon again saw her, some of the abdominal fluid was removed by an exploring needle and found to be a pure culture of the pneumococcus. The abdomen was incised and drained and the patient made a speedy and complete recovery.

The Use of Serum in Scarlet Fever.—H. Cumpston describes the septic and toxic forms of the severer cases and his experience with a polyvalent serum. This was obtained from horses immunized against cultures of streptococci which have been isolated from various cases of scarlet fever. These streptococci have been found in some cases in the blood, in other cases in the suppurative lesions which complicate pure scarlet fever, such as ulcerated throat and middle-ear disease. No particular type of streptococcus was, therefore, exclusively employed, the object having been to obtain as many organisms from as many cases as possible, so as to include a variety of strains. Use of the serum in 37 cases gave 26 recoveries and 11 deaths. There was a marked and distinct improvement in the symptoms in all the cases which eventually recovered. In 4 of the cases 50 c.cm. were given intravenously. In one case rigor and high fever followed, but in general this method seemed to give better results than by subcutaneous use. There was no renal irritation noted. Urticarial rash appeared a few times. Cervical suppuration resulted in three cases. While the author is not disposed to attach too much consequence to this single series of cases, he says that he was struck with the clinical course of many of the cases that recovered. Within forty-eight hours of the injection the temperature began to fall, became normal in another forty-eight hours, and remained normal, the cervical glands began to subside, the necrosis of the throat began to clear up, and the rhinorrhea either ceased or lost its purulent character. Not all of the cases showed so satisfactory a course, but most did very much better than would have been expected in the ordinary way without serum injection. In one case the temperature reaction to the first dose of serum was marked, but the improvement was not sustained. It may be that there was a case of invasion by several types of streptococci, some of which the particular serum used did not affect. Observation of these 42 cases leaves the distinct impression that the injection of the "antiscarlatinal" serum in large enough doses (not less than 50 c.cm.) and early enough in the disease—that is, as soon as the onset of rhinorrhea, swelling of cervical glands, and superadded rise of temperature, the signs of septic invasion, occurred—will produce a marked improvement in "septic" cases. In "toxic" cases little can be said in favor of the use of serum, but here some slight improvement was noticed in two cases.

Horsepox Directly Transmitted to Man.—A. F. Cameron reports the case of a stableman of thirty-two years of age, admitted to hospital with fever and swelling of the left arm and axilla. A rash on the arms and left hand had led to a diagnosis of smallpox. The lesions varied in size, but all resembled the lesion of a primary vaccination about the eighth or ninth day of its development, but they were more severe. The vesicular ring with turbid contents was well raised above the level of the surrounding skin on an indurated and tender base. Within the ring was a brownish-black, slightly depressed crust. In the larger lesions on the arms the diameter of the vesicular ring varied from 12 mm. to 9 mm. In two, situated one on the left forefinger, the other near the base of the left thumb, the vesicle was much smaller. In two to three days after admission the severe pain in the arms abated. The local indurations and lymphangitis gradually disappeared as the lesions crusted and the gland swelling subsided without suppuration. A point to be noted is that for several days the patient had severe constitutional disturbance. The fact that the lesions were confined to the left arm and hand (there was only one on the right arm), their uniform type and synchronous development, and above all their resemblance to the lesions of a primary vaccination, suggested that they were due to inoculation. It was later found that he had been treating a horse with an ulcerated mouth and it was doubtless due to this source that the infection was referable. There was an extensive epidemic of smallpox in London (where the case occurred) at the time, and the diagnosis of smallpox was natural. Out of ten thousand suspects fully one thousand were reexamined and found to be free from smallpox.

Cats as Plague Preventers.—A. Buchanan describes his experiences in India and dwells on the religious customs of the Mohammedans and Hindus, who venerate these animals. Inquiries over a large area showed that as a rule houses in which cats were kept were free from the plague. Rat-proof houses built of wattles are generally free also, but the ordinary mud hut is a breeding-place for the rodents. His general conclusions as to the advisability of keeping cats are thus stated: In the early days of plague epidemics many mistakes were made. Cordons were drawn around villages and towns so that infected people could not get in, but infected rats might steal in unobserved. Disinfection was practised with great vigor, but while this operation was in progress the rat was sitting comfortably in its burrow, ready to come out as soon as the disinfection operations were over. The plague patient was hastily segregated to a plague camp, but it is now known that plague (bubonic) is practically never conveyed direct from man to man, so that it has come to be a common saying that "the safest place in a plague epidemic is a plague camp," and those of us who have had charge of plague camps know that those servants who lived in the camp practically never took plague, although they were handling plague patients all day. A few cases of plague have been occurring daily in this district for some time, and from daily inquiries which are being made the author thinks there is good reason to believe that the duration of plague in India depends on the time it will take before it is generally recognized that the cat is the best plague preventer.

Berliner klinische Wochenschrift, May 25, 1908.

Osteoperiostitis in Chronic Icterus.—Beuttenmüller quotes the views of Teleky, who says that osteoperiostitis ossificans characterized by the well-known appearances of club fingers, spade hand, etc., may be found in the course of long suppurations, in some infections, in some chronic intoxications, in heart lesions, especially of the congenital kind, and in neoplastic diseases. Beuttenmüller has seen three cases of this affection accompanying chronic icterus, and has collected eight others from the literature. The icterus in his cases was due to probable hypertrophic cirrhosis in one case, probable carcinoma of the biliary passages in another, and a biliary cirrhosis in the last. The author considers the various explanations of this appearance in chronic icterus, and decides that the probable cause is the cholemia, as the most typical lesions observed in his first case disappeared after a successful cholecystostomy.

Münchener medizinische Wochenschrift, May 26, 1908.

Treatment and Prognosis of Chronic Otitis Media.—Von Ruppert has studied the material observed by Dr. Scheibe in the seventeen years from 1889 to 1906. During this time 1,118 cases of chronic otitis media were treated. Only 38 of them showed complications in the mastoid, the labyrinth, or the brain at the beginning of treatment. Five hundred and ninety-two, or 55 per cent., were uncomplicated cases, with central perforation; the treatment consisted of cleansing the auditory canal by injection of 4 per cent. boric acid solution, followed by the "air-douche," and a careful drying of the canal and the tympanic cavity. Then the introduction of very finely pulverized boric acid was practised. Cold wire sling or the curette was used to remove any hypertrophies of the mucosa or polyps of the external meatus. Under this treatment the suppuration was brought to an end in 371 cases, or in 93.9 per cent. of the 395 cases that were observed for a long period of time. At the same period of practice there were observed 489 cases of chronic middle-ear disease, with lateral perforation of the drum. In these cases the condition was much less amenable to treatment, the suppuration continuing over a longer period and a greater number of cases remaining unrelieved or requiring radical operative procedures. There were six cases of death, of which three were caused by abscess of the brain, two by sinus thrombosis, and one by meningitis. Von Ruppert concludes that chronic otitis media with central perforation is very amenable to treatment, never leads to complications during treatment, never attacks the bones, and therefore never requires operative treatment. Lateral perforation accompanying a chronic middle-ear disease has a much worse prognosis as to life, duration, and complete restitution of the patient to health.

Hemorrhage During Labor.—Schickele has studied fourteen cases of severe hemorrhage during labor, and comes to the following conclusions: The general state of nutrition, the development of the body, and previous health are very important factors in prognosis of severe bleeding during labor. Alcoholic women are more endangered by it than temperate patients. Multiparæ, patients who have bled in their previous labors, and who have had difficult or complicated deliveries, have a more serious prognosis, for their blood, considered as an organ, may have been harmed in the past. Patients with placenta prævia who have bled a good deal before being brought for treatment are in great danger. The author calls attention to the fact that the hemorrhage of extrauterine pregnancy is borne much better than bleeding during labor.

French and Italian Journals.

Early Intensive Treatment of Syphilis.—Carle advocates the use of intramuscular injections of soluble salts of mercury begun early in the disease, as soon as the diagnosis is positively established, as a means of preventing the bad effects of syphilis. The secondary period is so changed that a severe diagnostician would not be able to recognize the disease without the history of the initial lesion. It is important to select good subjects, free from any form of diathesis, alcoholism, or nervous predisposition. The patient is then given injections every other day of a soluble salt of mercury until fifteen injections of four centigrams have been given. A rest of about a week is taken and another series undergone; thus treatment is continued up to the end of the second year, the gray oil being used instead of the soluble salt after the second series of injections. The results are much quicker with the soluble salts and more pronounced. The second year the injections are less frequent, and the third year only two series are given. It is possible for the syphilitic to marry and have healthy children within three years of infection after this treatment has been carried out.—*Lyons Médical,* April 19, 1908.

Aphasia.—G. Mingazzini dissents from the opinions of Pierre Marie with reference to the relations of the lenticular nucleus to aphasia. He finds that the anterior third of the putamen has relation to the existence of aphasia, but the posterior two-thirds preside over articulation, thus showing how lesions of the lenticular nucleus cause dysarthria or motor aphasia. There are no reasons in pathological conditions or clinical facts to cause us to believe that the third frontal convolution is the center of the motor impulses of language. Heretofore too circumscribed limits have been assigned to the verbomotor region. It is necessary to enlarge its boundaries. The lobe of Broca is not the seat of images of words, but of syllables; thus when the area of Wernicke is destroyed we have aphasia characterized by the reiteration of many syllables, that is paraphasia. The auditory and motor images of language are mainly localized in the left side, but there is a supplementary center on the right. Examinations of hearing are necessary to determine whether the patient who does not comprehend owes this disturbance to a cerebral lesion or to deafness.—*La Riforma Medica,* April 20, 1908.

Book Reviews.

Diagnostics of the Diseases of Children. By Le Grand Kerr, M.D., Professor of the Diseases of Children in the Brooklyn Postgraduate Medical School; Pediatrist to the Swedish Hospital in Brooklyn; Attending Pediatrist to the Williamsburg Hospital, Brooklyn. Fully illustrated. Philadelphia and London: W. B. Saunders Company, 1907.

Diagnosis of disease may always be attended with difficulty, and this is particularly apt to be the case when the patient is a child. The present volume is designed to make this difficult task more easy of accomplishment. To some extent the author has succeeded in his task; for he has written a book that is well arranged and, as a rule, accurate. But there is little in the volume that is not contained in most of the text-books on pediatrics, and there are some important omissions. For example: there is no mention of empyema, and "purulent pleuritis" receives only inadequate notice; von Jaksch's anemia is not mentioned; leucocytosis shares the same fate, and the whole section on anemia is too slight to be of much value; the same remark applies to the few lines on cretinism, in which there is no reference made to Mongolian idiocy or infantilism, from both of which conditions cretinism has to be differentiated. The whole 540 pages could easily have been compressed into a much smaller volume; there are many much smaller books which contain considerably more information.

Progressive Medicine. A Quarterly Digest of Advances, Discoveries, and Improvements in the Medical and Surgical Sciences. Edited by Hobart Amory Hare, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College, Philadelphia. Assisted by H. R. M. Landis, M.D., Assistant Physician to the Out-Patient Medical Department of the Jefferson Medical College Hospital. December 1, 1907. Philadelphia and New York: Lea Brothers & Co., 1907.

The December number of Progressive Medicine, following along the same lines as in previous years, contains articles on (1) Diseases of the digestive tract and allied organs, the liver and pancreas; by J. D. Steele. (2) Diseases of the kidneys, by J. R. Bradford. (3) Surgery of the extremities, fractures, dislocations, tumors, surgery of joints, shock, anesthesia, and infections; by J. C. Bloodgood. (4) Genitourinary diseases, by W. T. Belfield. And (5) Practical therapeutic referendum by H. R. M. Landis. The first and third of these contributions are of considerable length, and occupy about one hundred pages each. The quality of the articles is of the usual high standard reached in this publication.

Treatise on Diseases of the Skin. For the use of advanced Students and Practitioners. By Henry W. Stelwagon, M.D., Ph.D., Professor of Dermatology, Jefferson Medical College, Philadelphia. Fifth Edition, Revised. Philadelphia and London: W. B. Saunders Company, 1907.

In five years this book has gone through four editions. The new edition contains very few changes, the most notable being found in some of the tropical diseases; thus the articles on Frambesia and Oriental Sore have been rewritten, and those on Verruga Peruana and Tinea Imbricata changed or added to. New chapters have been written on Dhobie Itch, Uncinarial Dermatitis, and Meralgia Paresthetica. The general plan of the work remains as before; the classification adopted is Hebra's system with a few slight modifications. A very useful feature of the book is the bibliography in connection with the various diseases and lesions under discussion.

The Diagnosis and Treatment of Diseases of Women, by Harry Sturgeon Crossen, M.D., Clinical Professor of Gynecology, Washington University; Gynecologist to Washington University Hospital and Chief of the Gynecological Clinic; Associate Gynecologist, St. Louis Mullanphy Hospital; Consulting Gynecologist to Bethesda Hospital, St. Louis Female Hospital and St. Louis City Hospital; formerly Superintendent of the St. Louis Female Hospital; Fellow of the American Association of Obstetricians and Gynecologists; Ex-President of St. Louis Obstetrical and Gynecological Society; Member American Medical Association, Mo. State Medical Association, St. Louis Medical Society, etc. With 700 illustrations. St. Louis: C. V. Mosby Medical Book and Publishing Company, 1907.

This volume is devoted entirely to the diagnosis and treatment of the diseases of women, and undoubtedly as such it will appeal to the general practitioner, who will find here a thorough and practical presentation of all that is necessary along these lines. The book is not intended for the specialist. Besides the clear and systematic arrangement of the subject, and the omission of etiological and pathological discussions, the volume is almost unique in the number and value of its illustrations. Upwards of fifty books have been drawn upon for these illustrations, and the author has supplied over two hundred of his own. The book contains chapters on: Gynecological examination methods; Gynecological diagnosis; Gynecological treatment; Diseases of external genitals and vagina; Lacerations and fistulæ of pelvic floor, perineum, external genitals and vagina; inflammatory and nutritive diseases of the uterus; Displacements of the uterus; Fibromyoma of the uterus; Malignant disease of the uterus; Pelvic inflammation; Other affections of Fallopian tubes, peritoneum and connective tissue; Diseases of the ovary and parovarium; Malformations; Disturbances of function; Invasion of the peritoneal cavity for the treatment of gynecological diseases; After-treatment of operative cases; Medicolegal points in gynecology. There is also an appendix containing formulæ, and an index. The addition of the numbers of the pages referred to in the table of contents would increase the value of the book.

Abel's Laboratory Handbook of Bacteriology. Translated from the Tenth German Edition by M. H. Gordon, M.A., M.D. Oxon., B.Sc. With additions by Dr. A. C. Houston, Dr. T. J. Horder, and the Translator. London: Henry Frowde, Oxford University Press; Hodder and Stoughton, Warwick Square, E. C., 1907.

This is a truly excellent little book, of pocket size and bound in oil cloth for use on the laboratory desk, in which a great deal of information in regard to bacteriological technique has been compressed into small space. It gives much useful matter, in regard to methods of sterilization, culture and staining methods in general and as applied to all the commoner organisms, methods of obtaining material for examination, methods of examining the blood in relation to immunity, which includes opsonic technique, the inoculation of animals, preserving cultures and specimens, and the examination of water, milk, dust, air, etc. The additions by the translator and his assistants seem timely and well advised and the translation is fairly good though occasionally such expressions as "frosted pear," meaning a ground-glass electric light bulb, betray their origin too directly.

Practical Nursing: A Text-book for Nurses and a Hand-book for all who Care for the Sick. By Anna Caroline Maxwell, Superintendent of the Presbyterian Hospital School of Nursing; and Amy Elizabeth Pope, Instructor in the Presbyterian Hospital School of Nursing. New York and London: G. P. Putnam's Sons, 1907.

This volume is intended for nurses and also for the laity. Between its covers there will be found much useful material; useful, that is for the nurse. The best part of the book is that dealing with the practical aspects of the subject. The more theoretical and scientific points are capable of improvement; for example the chemical formulæ on pages 197 and 198, expressions such as cholelithias (twice on one page), pediculosis for pediculus (three times on a page), the statement that ptyalin is a synonym of steapsin; there are also numerous misprints.

The Practical Medicine Series. Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Under the General Editorial Charge of Gustavus P. Head, M.D., Professor of Laryngology and Rhinology, Chicago Post-Graduate Medical School.

Volume X.—Nervous and Mental Diseases. Edited by Hugh T. Patrick, M.D., Professor of Neurology in the Chicago Polyclinic; Clinical Professor of Nervous Diseases in the Northwestern University Medical School; Ex-President Chicago Neurological Society; and Charles L. Mix, A.M., M.D., Professor of Physical Diagnosis in the Northwestern University Medical School; President Chicago Neurological Society, Series 1907. Chicago. The Year Book Publishers. $1.25.

As indicated in the title, this little volume represents the previous year's progress in nervous and mental diseases, the completed series of ten volumes being intended to cover the entire field of medicine and surgery. The publishers state that the series is intended primarily for the general practitioner. The neurologist will find Volume X very convenient for reference. The reputation of the special editors is sufficient guarantee both for the careful discrimination shown in regard to the selection of matter and the ability required accurately to abstract the various articles selected from the current medical literature. Those who wish to keep up to date will find the book a valuable help in their clinical work. New signs and symptoms, of use in diagnosis, new syndromes and diseases (if any), rare cases, and the results of experimental and clinical studies are described. The book has a good index and a number of excellent plates and diagrams.

Text-Book of Organic Chemistry for Medical Students. By Dr. G. v. Bunge, Professor of Physiological Chemistry in the University of Basel. Translated with additions by R. H. Aders Plimmer, D.Sc. (Lond.), Assistant Professor of Physiological Chemistry and Fellow of University College, London. London, New York, Bombay and Calcutta: Longmans, Green & Co., 1907.

The purpose of the present volume is to select for the medical student all that is important and essential for him out of the enormous and constantly increasing mass of facts found in the domain of Organic Chemistry. The author has been unusually successful in his praiseworthy effort to smooth the path of the medical student; and he has produced a book that is authoritative and also extremely interesting. The volume consists of seventeen lectures, which outline the main features of the subject; and, while the work does not pretend to supply all the student's wants in Organic Chemistry, it forms a most admirable introduction to larger and more detailed works.

Diseases of the Ear. By Hunter Tod, M.D. (Cantab), etc. London: Henry Frowde, Oxford University Press, 1908.

This manual well sustains the excellence already attained by its predecessors in the same series. The author's desire "to give a short and practical account of the diseases of the ear" has been very satisfactorily carried out. The chapters devoted to the external ear are concise, yet fully descriptive of the diseases and malformations with treatment. Naturally the space devoted to the middle ear and mastoid process constitutes a large part of the book. It is taken up in eight chapters, and is full of meat. The plates are original and arranged for easy demonstration. The anatomical descriptions are clear and sufficient. Pathology, so often dispensed with in the smaller books, is very consistently considered. The symptoms and treatment have been thoroughly described and we have nothing but praise for the chapter on "Intracranial Disease of Otitic Origin." Considerable interesting material can be found in Hunter Tod's expressed ideas on the subject of "Internal and Middle Ear Deafness." They are good. There is abundant evidence in the remaining chapters on diseases of the internal ear, deaf-mutism, and diseases of the ear in acute infectious diseases and of the nasopharynx, not only that the author has incorporated his ideas derived from extensive clinical experience, but that he also possesses the faculty of placing clearly before the student the important facts. The book is worthy of careful study.

Traité Pratique d'Analyse des Denrées Alimentaires. Par E. Gérard, Professor de Pharmacie et de Pharmacologie a l'Université de Lille et A. Bonn, Directeur du Laboratoire Municipal de la Ville de Lille. Avec 42 Figures dans le texte. Paris: Vigot Frères, 1908.

According to a law which became active in 1905, when food products are to be officially tested in France, four samples are taken. One of these, identified only by a number, is analyzed by the government laboratory according to certain prescribed methods, while the three others are reserved for the so-called *analyse contradictoire*. One of the samples is held in reserve for cases of disagreement, while the two others are entrusted to two experts, one selected by the authorities and the other by the defendant. The present volume is intended to serve as a guide for use in analyses of this sort and contains a description of the official methods as well as an elaborate discussion of whatever other procedures may be employed. All the ordinary comestibles are taken up and the tests for their purity and for the identification of adulterants are set forth clearly and with sufficient detail for practical use. The volume is excellent and may be commended to the attention of all who are interested in this subject.

Handbook of Cutaneous Therapeutics. Including Sections on the X-Ray, High-Frequency Current, and the Minor Surgery of the Skin, for the use of General Practitioners. By W. A. Hardaway, M.D., LL.D., Professor of Diseases of the Skin and Syphilis in Washington University, St. Louis, and Joseph Grindon, Ph.B., M.D., Professor of Clinical Dermatology and Syphilis in Washington University, St. Louis. Philadelphia and New York: Lea Brothers & Co., 1907.

This is a thoroughly practical manual, intended for the use of the non-specialist, dealing primarily with the treatment of diseases of the skin. When necessary, the symptomatology is treated of at length, and when of importance as an indication for intelligent treatment the subject of etiology is also considered, but these sections are given a subordinate place in the scheme of the work. The book is not a treatise on dermatology and its user must be already more or less familiar with the general features of diseases of the skin and must be able to diagnose the various affections in order to avail himself of its counsels. Given this essential preliminary knowledge, however, the practitioner will find his therapeutic path smoothed before him most satisfactorily. The directions for treatment are given clearly and the reader is not confused by a multitude of suggestions or by references to untried methods or to wonderful cures which have been found effective only in the hands of the proposers. The authors give in detail, under each disease, the plan of treatment which they have found of service or which is supported by other recognized authority. Numerous simple ormulas are given and the mention of unusual or unprocurable drugs is wisely omitted. The practitioner who has some knowledge of the general aspects of diseases of the skin will find this a safe and most satisfactory guide to treatment.

The Operation of Surgery. Intended Especially for the Use of Those Recently Appointed on a Hospital Staff and for Those Preparing for the Higher Examinations. By W. H. A. Jacobson, M. Ch. Oxon, F.R.C.S., Consulting Surgeon, Grey's Hospital, and R. P. Rowlands, M. S. Lond., F.R.S.C., Assistant Surgeon and Surgeon to the Orthopedic Department, Grey's Hospital; Joint Teacher of Operative Surgery in the Medical School. Fifth Edition. With seven hundred and seventy-seven Illustrations. In Two Volumes. Philadelphia: P. Blakiston's Son & Co., 1908.

This work on operative surgery, the first edition of which appeared in 1888, has long enjoyed a well-deserved reputation in Great Britain, but is comparatively little known in this country. The claim made in the title and repeated in the preface that the book is for the use only of young surgeons, those recently elected to hospital appointments, and not for those with a large surgical experience, is too modest. There are few surgeons of whatever age or experience who will not find it most helpful at times, and to those of moderate experience and without hospital appointments it will be found on brief trial to be indispensable. The descriptions of operations are so clear and the illustrations so well chosen and explanatory that any one with previous surgical training will, with their aid, be justified in attempting even unfamiliar operations, in an emergency, with confidence of success.

The arrangement of the book is sectional. Amputations, for example, are not treated of as a class, but in one part of the book those of the upper extremity are described; those of the lower extremity finding their place in another section dealing with all the operations on that part. The several parts deal with Operations on the Upper Extremity, Operations on the Hand and Neck, Operations on the Thorax, Operations on the Abdomen, Operations on the Lower Extremity, and Operations on the Vertebral Column. This plan has some advantages for the student who is supposed to study the anatomy of the region at the same time as the operations on the part, but it also has its disadvantages when one wishes to study the operative treatment of some special affection, aneurysm for instance, which may occur anywhere. This inconvenience is lessened in a way by means of the index, but it is still an inconvenience for one who wishes to study operative surgery in general and not the injury of some spinal part. There are two indices, one of names, the other of subjects. The construction of the first is on a plan which might well be followed in other works. Instead of the bare name of a surgeon with a reference to the page where he is mentioned, the reason for mentioning him is also given. Under Whitehead, for example, the references are to "excision of the elbow joint," "operation for cancer of the tongue," " mode of securing lingual arteries," "varnish," and "care of esophageal pouch." An index of names so constructed may be useful and is certainly an improvement over the usual collection of meaningless names. This improvement is offset, however, by the fact that each volume is separately indexed so that one has often to consult two indexes in order to find a special subject. The book is purely operative in its scope, containing nothing on pathology or the symptomatology of surgical diseases; the indications for operation are given when necessary, and in places the pros and cons of the operative management of certain conditions, such as appendicitis, are discussed more or less fully. The book is thoroughly up to the times, the comparatively recent Matas operation for aneurysm, for example, being fully described. It requires some search to find it, however, as its description is given in the section dealing with operation on the popliteal space. This is an instance of the inconvenience of the sectional plan of the work. It is a small objection, however, and is of no weight in comparison with the many points of excellence in the work.

Society Reports.

AMERICAN MEDICAL ASSOCIATION.

Fifty-ninth Annual Session, Held in Chicago, June 1, 2, 3, 4, and 5, 1908.

(Special Report to the MEDICAL RECORD.)

(*Continued from page 1016*)

SECTION ON DISEASES OF CHILDREN.

Wednesday, June 3—Second Day.

The Development of the Infantile Stomach.—Dr. D. E. ENGLISH of Milburn, N. J. read this paper. He said that the chief object of the scientific care of the infant was the development of a perfect adult with a normal adult stomach. The regularity of feeding was outlined and attention was called to the manner of feeding. He stated that development of the general musculature was necessary to the proper development of the stomach muscles. The capacity of the infantile stomach was not definitely known. Exercise of the stomach muscle was absolutely necessary for health and digestion. Irregularity of feeding was advocated where circumstances so demanded.

Dr. I. A. ABT of Chicago said that babies were often overfed. The method of feeding depended upon the child's capacity for digestion and the individual peculiarities of the patient.

Dr. A. JACOBI of New York said the two-hour limit between feedings was the best. He stated that even two hours after feeding material had been found in the child's stomach.

Dr. JOHN LOVETT MORSE of Boston advocated the two-hour feeding limit, and believed the stomach was empty at the end of two hours.

Dr. CLARENDON RUTHERFORD of Chicago said he preferred the three-hour limit of feeding, as this method secured rest for mother and child.

Dr. CHARLES DOUGLAS of Detroit stated that in the matter of feeding everything depended on the child's capacity for assimilation. He believed that the character of the stools was a good index to the solution of the feeding problem.

A Study of the Quantity and Quality of Breast Milk During the First Two Weeks of the Puerperium.—Dr. EFFA V. DAVIS of Chicago presented this subject, which was based upon a study of one hundred cases. The babies were divided into three classes, according to their ages. Each child was weighed before and after feeding. The average infant required from fourteen to eighteen ounces of milk daily. The diet of the nursing mothers was chiefly milk, though meat was permitted once daily. The supply of milk in the breasts was good. The children were fed at two-hour intervals during the day and three-hour intervals at night were enforced. During the first week loss of weight was noted in all the infants, but, at the end of two weeks sixty infants had regained in weight. Attention was called to the effect of emotions, anger, grief, etc., on the quantity and quality of mother's milk, and it was observed that the mothers were of a tranquil frame of mind during the stay in the hospital. These experiments proved that rest and tranquility of mind on the part of the mother, together with a regulated diet, increased the quantity and improved the quality of the breast milk.

The Problem of Breast Feeding.—Dr. J. ROSS SNYDER of Birmingham, England, read this paper. He said that a large percentage of early infant mortality was due to the absence of breast feeding. A strong plea was urged for a detailed study of the physiology and pathology of lactation. He stated that nursing mothers were, in many instances, not thoughtfully protected. Mothers were encouraged to suckle their offspring. Several instances were cited whereby the lives of a number of infants were saved with a daily milk supply which he had obtained from the breasts of nursing mothers. This milk was placed in bottles and conveyed to the unfortunate children who were deprived, otherwise, of maternal nursing.

A Consideration of Some Fallacious Standards Employed in Artificial Feeding of Infants.—Dr. GODFREY ROGER PISEK of New York read this paper. He said that some definite scientific method of artificial feeding was needed, and a plea was urged for its speedy development. The properties were desired and not the physical appearance of the substances used in feeding. He stated that a gain of weight in an infant was an index of proper feeding, and discouraged the caloric method of valuing food, since the results were too indefinite.

The Gospel of Top Milk.—Dr. A. JACOBI of New York presented this subject, in which he reviewed the process of intestinal digestion and summarized his remarks as follows: 1. Artificial feeding was never equivalent to mother's milk. 2. The alleged improvement in artificial feeding was overestimated. 3. Between mother's and cow's milk there were many differences. 4. Good results were obtained by a reduction of the fat to 2 per cent. 5. Feeding was more successfully managed by brains rather than mathematics. 6. Cane sugar was preferred to sugar of milk. 7. The cereal decoctions were increased when the baby showed a loss of weight. 8. Asses' milk was supplied when cows' and mother's milk produced unfavorable results in the child. 9. The gospel of top milk was a heresy.

High Fat Percentages in Infant Feeding: Causes and Effects.—Dr. THOMAS S. SOUTHWORTH of New York read this paper. He said the subject of fat percentage in artificial feeding was the important topic of the hour. Much valuable time was lost and progress delayed by misrepresented conditions of the stools of artificially fed infants. Curds were reported where none existed. He claimed that high fat errors were caused by miscalculations of percentages and misused top-milk methods. He believed rich milk contained fat in excess of 4 per cent. A knowledge of when and how formulas were used was important. He spoke of two classes of patients—those in whom normal amounts of fat produced indigestion and those disturbed by excessive amounts of fat.

Dr. C. F. WAHRER of Fort Madison said that some children thrived on anything. He thought the use of buttermilk was good, and he was not in favor of the mathematical top-milk methods.

Dr. JOHN LOVETT MORSE of Boston believed with Dr. Jacobi that brains were preferable to mathematics in infant feeding. He said that formulas gave best results when suited to the individual case.

Dr W. J. BUTLER of Chicago said that too much weaning was done before the proper time. Tuberculosis and insanity on part of mother called for a sudden weaning. He thought high fat percentages were harmful.

Dr. THOMAS M. ROTCH of Boston thought that the fat percentages as used were not too high. He denounced the use of patented foodstuffs in infant feeding. Milk formulas were too indefinite. He advised treatment of the individual child and explained that set rules for every case were useless.

Dr. J. A. WORK of Indiana said that rapid feeding of infants was harmful.

Dr. CHARLES DOUGLAS of Detroit believed that rice or barley water was the best diluent in milk mixtures.

Dr. THOMAS S. SOUTHWORTH of New York closing, said that many cases of weaning were advised by physicians who were ignorant of the laws of infant feeding. He stated that mothers were also responsible for many cases.

Hydrotherapy in Scarlatina with Special Reference to Tub Baths at 90° for Nervous Symptoms in Early Stages.—Dr. D. S. HANSON of Ohio read this paper, in which he reviewed the marked relief of convulsions and

other nervous symptoms afforded by the hot bath. He reported several cases in which satisfactory results were obtained by hydrotherapy in form of hot baths. He believed many complications were avoided by its use.

Dr. R. B. Gilbert of Louisville said that in his experience children objected to the bath, and advised colonic irrigations of normal salt solution as a substitute.

Dr. Hanson, in closing, said that he had experienced no difficulty in the question of bathing in the cases reported.

The Diagnosis of Pneumonia in Infants.—Dr. Roland G. Freeman of New York presented this subject. He believed that the symptoms and not the physical signs determined the diagnosis. He reported a typical case and based his diagnosis on the following points: 1. Sudden onset. 2. Mental depression. 3. Rapid respirations. 4. Fever and cough. 5. Rigid condition of muscles of neck and upper extremities.

Dr. W. W. Butterworth of New Orleans said that many cases of pneumonia were mistaken for some abdominal trouble, especially appendicitis, and stated that a careful examination of the lungs in every case was good practice.

Circulatory Disturbances in Diphtheria.—Dr. John Howland of New York read this paper. He reviewed a series of cases which he had carefully studied and presented the following conclusions: 1. Fatty degeneration of the heart muscle was frequently found. 2. Thrombosis and embolism were not so common. 3. Death was caused by paralysis of the vaso-motor centers. 4. The drugs used in the treatment of cardiac disturbance were digitalis, caffein, and nitro-glycerin. 5. Indications for medication depended on the condition of the first sound of the heart. 6. Experiments proved that a great disturbance of metabolism existed even into convalescence.

A Summer Camp for Treatment of Sick Babies.—Dr. Walter Graham Murphy of Hartford presented this subject. He said that this camp was established for the treatment of children who suffered principally from gastro-intestinal disorders. Four tents were erected along the Connecticut River in Riverside Park, Hartford. The number of cases treated during the summer months has averaged from ten to twelve daily. The patients were brought to the camp by their mothers, who received instructions as to the management of the infants when at home. The mortality of some sixty cases treated during a certain period was about 18 per cent. This was explained by the fact that many of these cases were moribund when presented for treatment. A more extensive camp was contemplated in the near future.

Dr. J. M. Beffel of Milwaukee said that a similar plan of outdoor hospital was established in Milwaukee. It was situated on Lake Michigan. He suggested an adoption of this plan by other large cities.

Dr. T. W. Kilmer of New York said that the mortality quoted by Dr. Murphy was unusually large. He thought that the object of this camp was a good one.

Dr. W. F. Allen of Chicago stated that Chicago had an institution that carried on this manner of work.

Dr. Charles G. Kerley of New York thought that the mortality quoted by Dr. Murphy was too high, and asked what treatment was carried out in the summer camp.

Dr. J. W. Van Derslice of Chicago urged the formation of clubs and societies to maintain these camp hospitals.

Dr. Murphy closed the discussion. He said that the mortality rate quoted was not guaranteed as the exact per cent. of deaths. He was not certain, but thought it ranged from 14 to 18 per cent.

The Prephysical Signs of Tuberculosis in Children.—Dr. W. C. Hollopeter of Philadelphia read this paper. He said that tuberculosis in children had no definite incubation period. He classed it as an infectious disease and stated that sometimes it remained latent throughout the life of the individual. A plea was urged for public measures to overcome the spread of this disease. Attention was called to the presence of enlarged bronchial glands, together with loss of weight, anemia, and gastro-intestinal catarrh. These were important incipient signs. He referred to the protean types of expression of tuberculosis which occurred in childhood.

Dr. A. W. Fairbanks of Boston thought it was rather difficult to discriminate between enlarged bronchial glands and the thymus body.

Dr. R. B. Gilbert of Louisville said that the tubercle bacillus was found in the stools before glandular enlargement was noted. Night sweats were likewise an early sign.

Dr. C. G. Kerley of New York said that in a certain New York hospital tuberculin was employed to determine early cases of tuberculosis. He said that by this method many cases of supposed bronchitis were proved incipient cases of tuberculosis.

Dr. Alfred Friedlander of Cincinnati said that lymphocytosis was a good early sign of tuberculosis. He advised use of *x*-ray in determining enlarged glands.

Dr. J. W. Van Derslice of Chicago thought an accentuated pulmonic second sound was a good early sign of pulmonary weakness.

Dr. W. J. Butler of Chicago placed importance on the ophthalmic reaction in these cases. He suggested that the examination of the eyes in every suspected case was a good practice.

Dr. J. F. Hultgen of Chicago said all depended on the early recognition of an adenitis. The blood showed an increase in the lymphocytes, and the findings were practically those of a case of chloranemia.

Dr. Hollopeter closed the discussion. He said that the smears obtained from the throat secretion showed the presence of the tubercle bacillus very early in the disease. He believed the blood findings were important.

Adaptation of Fresh Air Treatment of Tuberculosis to Pediatric Practice.—Dr Alexander McAllister of Camden, N. J. read this paper. He summarized his remarks as follows: 1. No race was exempted from tuberculosis. 2. Outdoor life was a necessity for many. 3. Majority of infants were predisposed to tuberculosis. 4. Tuberculosis was home-bred. 5. Cold, damp air was not fresh air. 6. Treatment all depended on the age and condition of the child. 7. Treatment in general was fresh air and suitable diet.

Dr. D. E. English of New Jersey said he believed in the fresh air treatment. He likewise believed that cold air was not always fresh air.

Dr. C. F. Wahrer of Fort Madison said that children were benefited by fresh air treatment at night as well as day. He stated that tuberculosis was not so common among children of the rural districts.

Dr. A. W. Fairbanks of Boston said the cases of tuberculosis in children in large cities were of two classes—the well marked and those predisposed to the disease. He suggested sanitarium treatment for well-marked cases, and outdoor schools for the incipient cases.

Dr. J. W. Beffel of Milwaukee said that early diagnosis of tuberculosis was desired at all times. He criticised modern architecture and said the unsanitary conditions of the home were responsible for many cases. He thought that an insufficient amount of proper food accounted for many cases. He believed that a careful watch was necessary in all children under ten years, as this was the crucial period.

Dr. P. J. Allen of Chicago said that fresh air was good when administered night and day. Incipient cases progressed more favorably when kept from school.

Personal Observations in Scarlet Fever in Children.—Dr. Charles G. Kerley of New York read this paper,

which was based on a study of 500 cases. He summarized his remarks as follows: 1. Scarlet fever was both contagious and infectious. 2. Cases were rarely found under age of one year. 3. Incubation period was four to eight days. 4. A distinct angina was present in the majority of cases. 5. Nephritis occurring during the course of disease depended on the nature of the epidemic. 6. Period of desquamation was feebly contagious. 7. Hydrotherapy was employed for febrile conditions. 8. Potassium chlorate was given in three-grain doses for the angina.

An Epidemic of Hemorrhagic Nephritis Following Scarlet Fever.—Dr. C. F. Wahrer of Fort Madison read this paper. He said his deductions were obtained from a study of an epidemic of 200 cases and concluded as follows: 1. The etiology of scarlet fever was unknown. 2. Thirty-five per cent. of the cases had nephritis. 3. The mortality was but 3 per cent. 4. There were no relapses. 5. The number of cases in the epidemic was unusually large. 6. Treatment was symptomatic.

Dr. Henry E. Tuley of Louisville said that isolated cases of scarlet fever were more severe than those noticed in an epidemic.

Dr. R. B. Gilbert said that prophylaxis was the first step in the treatment. He gave no medicine in his cases as a rule.

Dr. H. M. McClanahan of Omaha believed that scarlet fever was contagious even after the third week.

Dr. F. A. Churchill of Chicago said it was best to quarantine until desquamation was completed.

Dr. B. H. Blair of Lebanon cited a case of hemorrhagic nephritis which followed diphtheria.

Dr. Kerley closed the discussion. He said the disease was feebly contagious during desquamation. Chlorate of potassium gave good results in his hands.

Dr. Wahrer closed the discussion of his paper. He said he used very few drugs in the treatment of his cases.

Thursday, June 4—Third Day.

Officers.—The following officers were elected for this section for the session of 1909: *Chairman,* Thomas S. Southworth, of New York; *Vice-Chairman,* C. F. Wahrer, of Fort Madison, Ia.; *Secretary,* W. W. Butterworth, of New Orleans; *Delegate,* R. B. Gilbert, of Louisville; *Alternate,* A. W. Fairbanks, of Boston.

The Ambulatory Treatment of Pneumonia in Infants and Young Children.—Dr. T. W. Kilmer of New York read this paper, which was based upon the study of thirty-six consecutive cases treated at the dispensary. He summarized his deductions as follows: 1. The ages of the children treated ranged from two to twelve years. 2. The patients were brought to the clinic in all kinds of weather. 3. Mothers were instructed as to hygiene, fresh air, clothing and food. 4. All directions were written. 5. The use of the stethoscope was necessary in determining localized areas of congestion. 6. Absolute rest of the patient was advised. 7. Castor oil was used for laxative effect; mustard plaster for counter irritation; hydrotherapy for high temperatures, and ipecac for the cough. 8. The mortality was 2 per cent.

Dr. S. McHamill of Philadelphia said children were liable to infection from contagious disease in dispensary services. He thought exposure to all kinds of weather was unsafe, and advised hospital treatment.

Paralytic Dementia in Childhood.—Dr. A. W. Fairbanks of Boston reported a case of a boy 14 years old, who, until the age of 12 years, was apparently in good health. At this time he became irritable and lost control of his actions. His speech was faulty and he suffered from convulsions and tremors. The autopsy confirmed the diagnosis of paralytic dementia. Syphilis was the only cause of this affection, though the family history in this case was not definite. The mother, however, was suspected as having had specific trouble.

Dr. S. J. Walker said that paresis was very rare at this age. He believed that all cases reported occurring in children were congenital in origin, and cited a case of brain tumor that simulated paresis. He desired to know the ocular findings in the case reported.

Dr. Fairbanks, in closing, said the cardinal symptoms of brain tumor were absent in this case. The pupils were dilated and unequal.

Hyperpyrexia in Children: Causes and Treatment.—Dr. Philip Marvel of Atlantic City presented this subject. His observations were drawn from a study of forty-eight cases, and epitomized as follows: 1. The term pyrexia signified a complex morbid process, characterized by an elevation of temperature. This was caused by (a) microorganisms, (b) traumatism, (c) drug poisoning, (d) neurotic affections. 2. Hyperpyrexia was merely an exaggerated form of pyrexia. 3. Hyperpyrexia was not as fatal to life in childhood as in adolescence. 4. Hydrotherapy was the proper form of treatment for this condition.

Hemorrhages of the Suprarenal Capsules in the Newly Born, with Report of Two Cases Due to Infection.—Drs. Jennings C. Litzenberg and S. Mark White of Minneapolis presented this paper, reporting two fatal cases within the first week of life. One case showed focal necrosis in the adrenals, intestinal hemorrhage and lobular pneumonia, while the other presented evidences of a large hemorrhage ruptured into the abdominal cavity. The observations were summarized as follows: 1. A review of the literature failed to reveal a definite cause of this condition. 2. Suprarenal hemorrhage was more common than hemorrhage into other viscera. 3. Anatomic peculiarities and active or passive congestion are etiological factors. 4. The pneumonia bacillus in pure culture was found in the adrenals. 5. Death resulted from a cessation of the physiological function of the glands.

Dr. A. Jacobi of New York said that many deaths within the first week of life were due to meningeal hemorrhages. He desired to know if there was any connection between the sudden death of these cases and the hemorrhage.

Dr. Litzenberg said he was unable to explain the sudden death and its connection with the hemorrhage.

Cerebellar Symptoms in Hydrocephalus, with a Pathologic Report of a Case Associated with Syringomyelia.—Dr. John H. W. Rhein of Philadelphia read this paper, in which he reported a case of a boy eight years old. The symptoms in this case were vomiting, vertigo, disturbance of vision and convulsions. The physical examination showed a protrusion of the eyeballs, enlargement of the head, and spasticity of the legs. Death occurred at the end of two years. The autopsy showed intense hydrocephalus, two cysts at the cerebellar pontine angles and syringomyelia.

Chronological and Anatomical Age.—Dr. Thomas Morgan Rotch of Boston presented this subject, which was illustrated by a series of röentgenographs. The investigations were carried out with a view of establishing a reliable index as to the age of a child, with special reference to the child labor law. The experiments were performed on two hundred children, and the results were summarized as follows: 1. Röentgenographs of the hand and wrist supplied more reliable data of the child's general development than did the chronologic age method. 2. Children of the same grade in school showed vast differences in the anatomic development of bones of the wrist, and hence the general development indicated differences. 3. The Röentgen ray was always reliable and efficient. 4. A plea was urged for physicians to take up the subject in the interest of the child. 5. The anatomic development of the wrist was probably the best reliable index of the child's age.

Dr. A. Jacobi of New York said that this was a new

study. It was anatomy combined with physiology. The further development of the subject was urged.

Dr. F. A. Abt of Chicago believed that this standard was useful in determining when children were best fitted for school work.

Dr. Rotch in closing the discussion, said that his experiments were not completed as yet, but he believed a provisional index of the child's age was found in the anatomical development of the bones of the wrist.

A Study of the Anemias of Infancy.—Dr. John Lovett Morse of Boston read this paper. His deductions were as follows: 1. The most characteristic features found in the blood of infants suffering from anemia were the relatively low percentages of hemoglobin, the relatively large number of non-granular cells and the morphologic changes in the red blood corpuscle. 2. Chlorosis did not occur at this age. 3. Pernicious anemia was rarely encountered in infants. 4. Secondary anemia was common and often associated with enlargement of the spleen. 5. Leukemia was very rare in infants.

The Vaccine and Serum Treatment of Gonorrhea in Female Children.—Dr. W. J. Butler and J. P. Long of Chicago presented this subject. Their summary was as follows: 1. No local treatment was given. 2. The most effective dose was determined by the opsonic index. 3. Of twelve acute cases treated, nine completely recovered. 4. Of thirteen chronic cases treated, nine recovered. 5. The average period of treatment was from thirty-nine to forty-three days.

The Vaccine Treatment of Gonococcus Vulvovaginitis in Infants and Children.—Drs. F. S. Churchill and A. C. Soper, Jr., of Chicago presented this paper. The results of their observations were as follows: 1. Gonococcus vulvovaginitis was an obstinate affection and much dreaded in children's hospitals. 2. No local treatment was advised. 3. The dosage depended on the opsonic index. 4. Inoculation probably shortened the stay of patients in the hospital. 5. It was impossible to state whether this form of treatment shortened the duration of the disease.

SECTION ON PRACTICE OF MEDICINE.

Thursday, June 4—Third Day.

Dr. C. F. Hoover of Cleveland in the Chair.

Officers.—*Chairman*, Dr. Joseph L. Miller of Chicago; *Secretary*, Dr. Wilber Tileston of Boston; *Orator in Medicine*, Dr. James B. McElroy of Memphis, Tenn.; *Delegate*, Dr. George Dock of Ann Arbor, Mich.; *Alternate*, Dr. William S. Thayer of Baltimore.

Disguised Starvation—Dr. Nathan Rosewater of Cleveland read this paper and made the following summary: He submitted what to him seemed a hitherto overlooked self-evident physiological principle governing the nutrition of man, but not that of animals, namely, unlike animals who must follow instinct because possessing no higher controlling faculty, man's highest faculty, reason, presided over his instincts, appetite, fullness, satiety, etc., giving to those due but not absolute weight in deciding and controlling his final acts. Man's yielding to over-indulgence of food through uncontrolled appetite or his repeated refusal to eat through lack of appetite were physiological errors and injurious to health. Having no appetite was not a criterion for insufficient eating, since man possessed abundant processes for digesting his food, without appetite. Disguised starvation was prevalent from insufficient food intake, without reason (mainly from economy, worry, and ignorance), causing an atonic state and rendering the subject susceptible to many intercurrent diseases, readily resulting in tuberculous and other infections. To save all classes from such results, the public should be educated to know by tables of normal weight and normal height; those far away to either side from the normal range should be taught to use good reason, judgment and will, so as to keep within the normal by controlling the quantity, quality, and time of their meals. The superiority and progress of civilized man depended in recognizing and controlling his powers to his greatest advantage.

A Case of Syphilitic Infection of Fourteen Years' Duration.—Dr. Henry C. Buswell of Buffalo reported such a case in which the point of real interest was the persistency and duration of the fever which, in his experience, had not been characteristic of syphilitic infection. Had there been the slightest doubt of the correctness of the original diagnosis of syphilis it had been absolutely dispelled by the results of the treatment.

Dr. Joseph L. Miller of Chicago called attention to the resemblance between tertiary lues and intermittent malarial fever, with the long freedom from fever. He had seen four cases diagnosed as cholecystitis because, at some time, there had been some pain over the site of the gall-bladder. Two other cases had been diagnosed as pulmonary tuberculosis because of an accompanying bronchitis. In two other cases no diagnosis was made. With one or two exceptions these patients had a leucocyte count of from 10,000 to 12,000, and another who was autopsied had a count of 12,000.

Dr. Charles G. Stockton of Buffalo believed the paper to be a very important one because it emphasized a fact that had not been generally recognized; these patients might have a long-continued fever, intermittent in character, which did not go on to recovery under ordinary treatment, but responded promptly when an antisyphilitic treatment was given.

Dr. William S. Thayer of Baltimore said that these cases might well be confounded with cases of typhoid fever. He recalled and reported such a case.

Remissions in Pernicious Fever.—Dr. Walter L. Bierring of Iowa City read this paper. He said that out of a series of twenty-five cases seen during the past few years he had selected a few of the most striking as illustrative of remissions in pernicious anemia. In several instances where fermentative changes in the intestine were a prominent symptom high colonic irrigations with normal salt solution seemed to be connected with remissions or improvement. A certain parallelism was maintained between the changes in clinical signs and blood findings, the blood condition being usually a fair index of the degree of improvement in the patient, and also of the reactive changes in the hemotopoietic organs, especially the bone marrow. Some French writers laid stress on the value of the syndrome "leucopenic-lymphocytoses" and diagnosis and prognosis. The disappearance of the leucopenia and modification of the leucocyte formula suggested improvement. Although the blood underwent a marked improvement in the remission period it still preserved certain abnormal features indicating that a disturbance in the hemogenetic function continued to exist. That pernicious anemia was an expression of a toxemia, probably enterogenetic in origin, was borne out by clinical studies and experimental demonstration. Therefore care of the intestinal tract was a special factor in the treatment. The recent case of Herter attributing etiological significance to specific fermentations in the intestinal tract was very suggestive. While the present lack of etiologic unity prevailed it was evident that the explanation of the remission phenomenon, and the finding of a definite curative measure, were problems still to be solved.

A Clinical Method for the Determination of the Sodium Chloride Content of the Blood and Other Body Fluids.—Dr. Douglas Vanderhoff of Richmond, Va., read this paper. He said that the sodium chloride content of the blood and body fluids might be accurately estimated by an adaptation of Volhard's method of quantitative chloride determination after first precipitating and oxidizing the albumin bodies by nitric acid. The method

required one cubic centimeter of blood, aspirated from a vein, and accurately measured in a volumetric pipette. The clinical application of this method showed a practically constant value for NaCl in a variety of conditions such as nephritis with and without edema, uremia, pneumonia, epilepsy, gastric anacidity, and conditions of cachexia. Variations in the amount of NaCl depended upon the relative proportion of plasma and corpuscular elements in the specimen examined, with the highest values in cases of anemia and the lowest figures in patients with venous stasis due to heart, kidney, or lung affections. In conclusion he said: (1) The proportion of sodium chloride in the plasma of the blood was constant in conditions of health and disease. (2) The term "chloridemia" was unjustified.

Experiments Upon an Ash-Free Diet and Salt Metabolism, with Special Reference to Edema in Diabetes Mellitus.—Drs. Elliot P. Joslin and Harry W. Goodall of Boston presented this communication and drew the following conclusions: (1) The withdrawal of salt from the body did not lead to the production of acid intoxication of the diabetic type, nor did it increase an acidosis already existing. (2) Edema in cases of diabetes mellitus presented marked acidosis and this frequently occurred coincident with restriction of the carbohydrates in the diet. (3) This edema was not due to the simultaneous administration of sodium bicarbonate. (4) The edema was probably caused by the increased production of acids causing injury to the kidney, thereby leading to retention of salt. (5) Patients in diabetic coma almost without exception presented no signs of edema, and also diminished chlorine in the urine if alkalies were given. (6) The careful administration of salt along with sodium bicarbonate was recommended in the prophylactic and actual treatment of diabetic coma.

Pellagra.—Dr. R. H. Bellamy of Wilmington, N. C., made this report. He said that pellagra was a trophoneurotic disease, affecting the cerebrospinal, digestive, and cutaneous systems. Its immediate cause was a fatty oil or extractive that developed in fermenting and decomposing maize. Pellagra occurred in Egypt only where corn was eaten. This disease was not recognized in this country prior to 1907. During that year eighty-eight cases were reported as occurring at Mount Vernon, Alabama. This epidemic was very fatal, sixty-four percent. dying, and the maize eaten by these patients was found to be decomposed and unfit for food. A sporadic case was reported in September, 1907, from Texas. Besides the case Dr. Bellamy reported, there were a half-dozen more which had occurred in his community. There was no doubt but that the disease had been occurring there for many years. There was a fatty degeneration of the liver, kidneys, spleen, and myocardium, atrophy of the muscular coat of the intestine, and sometimes ulceration. There was also atrophy, sclerosis, and pigmentation of the skin. There was pigmentary degeneration of the cells of the brain, cord, liver, spleen, kidneys, and heart. The abdominal viscera were usually atrophied. The chronic form usually began with lassitude, headache, and anorexia, with a tense epigastrium, and possibly with nausea and vomiting. A serous diarrhea soon followed. In ten days to two weeks there developed an erythema, confined to the portions of the body exposed to the sun. The erythema was usually bright red in color, very much like a sunburn, and disappeared on pressure, unless hemorrhagic. Often there occurred vesicles and bullæ, with very little itching and burning compared to the process. Generally in two weeks the erythema subsided and desquamation took place. After three recurrences the patient usually became much emaciated and the diarrhea would increase in severity, and melancholia, increasing to dementia, occurred. There might be edema and foul sweats. Epileptiform convulsions might occur. As a rule there was an albuminuria. The blood changes were unimportant. The disease lasted five years, on an average, but might be prolonged fifteen years. The acute form began with pain in the epigastrium, headache, nausea, and vomiting, and this was followed by a severe diarrhea and stomatitis. The stools were often bloody, and occasionally there was bleeding from the gums and tongue. The patient rapidly became emaciated. There was delirium and a typical typhoidal course, and death usually occurred in ten days or six weeks. He said he had never seen such a case recover. The report of three cases followed.

Prominent Symptoms in the Diagnosis of Gastric and Duodenal Ulcers.—Dr. Christopher Graham of Rochester, Minn., contributed an interesting paper on this topic. He said the accurate differentiation between duodenal ulcers and ulcers of the pyloric end of the stomach offered great difficulties, and was often impossible. He laid emphasis upon four points. First, the periodicity of the attacks of gastric and duodenal ulcers. Following the period of attack came an intermission of days, weeks, or months, appearing often as unaccountably and as suddenly as did the distressing symptoms. These attacks repeated at irregular intervals for years and continued for varying periods, increasing in intensity, perhaps but slowly, the intermission shortening, until finally, the patient might fail to reach at any time the complete ease of previous years. These periods of complaint with the periods of intermission, each covering days or months, were so characteristic that, excluding other details, this one feature was often quite sufficient to warrant a probable diagnosis. Second, the number of years through which these attacks and intermissions or remissions had run before surgical relief had been advised, or perhaps accepted. As one's experience lengthened he was inclined to the belief that error was much oftener to be laid at the door of conservative surgery than at the door of aggressive surgery, and for that reason the sufferer failed to get the early relief which was secured only through surgery. In a series of 258 duodenal cases there were but few with histories of less than one year, and in these the symptoms were clear and often urgent. In their histories the repetition of spells with intermissions or remissions, together with long years of trouble, had been clear cut in 90 per cent. of cases. Third, the characteristics of pain, its great diagnostic significance and its place in differential diagnosis. Pain in gastric ulcer was the most constant symptom and perhaps the most characteristic in its manifestations. Not the kind of pain, or location of the pain, but the time of pain was the distinguishing feature. Usually two to five house after a hearty meal the burning, gnawing feeling began, increasing in intensity until vomiting or irrigation had removed the offending material. Food eased the pain, and the heartier the meal the longer the relief. This was especially true in duodenal ulcer. Gradually, however, this relief lessened, until late in the history and after the patient had been long a "surgical" case, food eased but little. The pain came in definite periods of attack; it came daily or two or three times a day during this period; often it came in from two to five hours after a meal and was therefore premeal as often as aftermeal. It was epigastric, radiating seldom to other areas and was relieved in part, if not wholly, by food, drink, alkalies, vomiting, or irrigation. Fourth, the ready control of all symptoms during the period of attack by the measures that control pain, such as food, alkalies, irrigation, vomiting, etc.

Compensatory Diarrheas.—Dr. Heinrich Stern of New York presented this paper. He said that compensatory diarrhea might supervene in manifold conditions and at various stages of a progressive affection. In exceptional instances only would compensatory diarrhea be encountered as a terminal symptom. It was always symptomatic of arrest or perversion of the function of the skin, lungs, kidneys, of the organs of internal secretion. Its immediate effect tended to systemic correction or compensation

in the majority of instances and was, therefore, of a salutary nature. As a matter of fact most compensatory diarrheas had a corrective tendency as far as the bowels were concerned, but they did not call forth a general compensatory effect. By compensatory diarrhea he meant a phenomenon of varying degree and duration, apt to ensue and to return with more or less frequency in the course of systemic deterioration, and characterized by the diarrheal discharge of incompletely or perversely catabolized substances, or by that of catabolic products normally excreted by other emunctories. He generally recognized three general types of compensatory diarrheas, viz., those which were concomitant with deficient or perverse catabolic processes; those which were the consequences of functional or structural disease of certain excretory organs; and those occurring during the period of physiological systemic decline. Dr. Stern put forth this general prognostic axiom, that as long as a diarrheal process continued to compensate efficiently for loss of function of the skin, lungs, kidneys, and the organs of internal secretion, the patient was in a satisfactory osmotic equilibrium and there was little immediate danger so far as life itself was concerned, and the pathological or artificial suppression of the diarrheal discharges might give occasion to very grave symptoms and even cause death, in case the functionally deficient organs had not regained their activity meanwhile. A true compensatory diarrhea should not be interfered with unless there was sufficient evidence that the localized intestinal irritation and hyperemia unduly prolonged the increased peristalsis. Inasmuch as a compensatory diarrhea was symptomatic of the insufficiency of excretory function in general, it indicated the points toward which treatment should be directed. Such treatment should tend to the stimulation of the catabolic processes and the regeneration of the eliminative qualities of the skin, lungs, and kidneys.

Acute Insufficiency of the Suprarenals.—Dr. R. S. Lavenson of Philadelphia read this paper. He said that hemorrhage of the adrenals had been generally recognized as a common pathological finding in still-born infants or those dying shortly after birth; but in none of the countries outside of France had acute insufficiency of the adrenals become a factor in medical diagnosis in advanced life as well as in infants. That a symptom complex dependent upon acute insufficiency of the adrenals did occur was well exemplified by the case which he reported in full. The following classification he believed would serve as a basis for clinical consideration: (1) Cases of sudden onset with epigastric pain and tenderness, vomiting, profound prostration, feebleness and rapidity of pulse, coldness of extremities, lumbar tenderness and at times diarrhea, and abdominal distention, followed within a few days by death. (2) The asthenic type in which the predominant feature was a profound asthenia ending within a few days in death. (3) The nervous type, in which the predominant symptoms had been either convulsions, coma, delirium, or a typhoid state. (4) Cases of sudden death. At autopsy nothing except a destructive lesion of the adrenals, usually hemorrhage, had been found. (5) Cases occurring in association with a purpuric eruption or hemorrhages into the abdominal viscera. Of all of the symptoms the most constant and one of the most characteristic was a greater or less degree of asthenia.

Trichiniasis, with Special Reference to Eosinophilia and Diagnosis.—Drs. S. Marx White and Chelsea C. Pratt of Minneapolis presented this paper, which was read by Dr. White. The family consisted of thirteen individuals. Nine of these ate raw infected pork and became ill. Four did not eat the pork and developed no symptoms. A boy, seven years old, died twenty-one days after the infection occurred. Abstracts of the individual histories and physical examinations were presented. They discussed the special points in diagnosis of trichiniasis as brought out in these cases, together with those reported in a former series. The gastrointestinal symptoms usually began in about two days, sometimes earlier, and consisted in diarrhea, more rarely constipation, sometimes accompanied by nausea, vomiting, and cardialgia. The fever might be high and persistent. The myositis was well known. Edema of the face usually began about six days after the infection and was most characteristic about the eyelids, and the slight reddish hue was very suggestive of this disease. They believed this to be one of the most important early suggestive signs. It might persist for from ten days to two weeks or even a month or more. Edema of the extremities or of the trunk was not noted as early as in the face. Its development was considerably later. Eosinophilia was usually well developed when the cases were first seen; in one of their cases it was noted first on the ninth day almost coincident with the onset of muscular symptoms. The polymorphonuclear count varied widely and was highest as a rule in the most severe cases. Mixed infection might be responsible for the increase in number of the polymorphonuclear neutrophiles in all cases. Some of the cases showed an increase in the lymphocytes in the later periods of the disease. The increase in eosinophiles was quite constant, both as regards percentage and absolute number per cubic millimeter. Glandular swelling was noted in only three of their cases, and appeared to be directly associated with the myositis. Alopecia was noted as a late symptom, but did not occur in the children. They called attention to the disease in order to emphasize again the principal points in diagnosis and make its recognition by the general practitioner more frequent. The typical symptoms were: (1) Early and sometimes persistent diarrhea, with or without gastric symptoms, often accompanied by headache and backache. Constipation might replace the diarrhea. (2) Fever might be high and persistent. It was usually moderate and continuous. (3) Careful examination of the body after the eighth day would give evidence of myositis. (4) Edema of the face might begin as early as the sixth day. Its location and appearance were very characteristic. Sweating occurred, but it had no particular significance. (5) Eosinophilia was present except possibly in cases of overwhelming infection, when they must rely upon evidences of severe myositis, unquestionable history of infection with living parasites, or excision of portions of the muscle for a diagnosis.

Modifications in the Clinical Course of Typhoid Fever Under the Influence of Menstruation and the Successive Menstrual Epochs, with Remarks on Treatment.—Dr. Alfred Stengel of Philadelphia presented this paper. He said the symptomatology of typhoid fever was regarded too exclusively from the point of view of the infection. The infectious process, and not the individual, occupied the center of attraction. So far as treatment was concerned, and this applied more to tuberculosis than to typhoid fever, a stereotyped course and machine-made methods were prescribed and, if the progress was unfavorable, the blame was attributed to exceptionally severe infection while at most a vague general suspicion of lack of resistance or unusual susceptibility was admitted. That antecedent pathological conditions, whose results might be to an extent controllable, and even physiological conditions, might influence the course of severe infections, as well as other diseases, did not enter enough into consideration. One saw this in the general disregard of the effect of pregnancy on the course of pulmonary tuberculosis and cancer. So far as typhoid fever was concerned he said that one might very profitably investigate and report the untoward influences of an old nephritis, or precedent nervous disease and of the tobacco and alcohol habit. He wished to address the section, however, on the influence of a purely normal function which, under the peculiar conditions of the infection, became capable of exercising unusual effects that modified the course of the disease. These modifications in the symptomatology had their prin-

cipal importance in the fact that they were likely to lead to misinterpretations. Writers made little mention of any relation between menstruation and the disease, or the reverse, except to call attention to the fact that the onset of menstruation might be delayed by the occurrence of typhoid fever, and that the succeeding period or periods might fail to occur during the continuance of the infection, and that various other minor disturbances might be met with. For some time Dr. Stengel had recognized a modification of the course of typhoid by the menstrual period. In young women the event of typhoid fever was often unusually severe, and was more decided when the menses failed to appear; in some cases very severe symptoms occurred though the flow was normally established or excessive. The onset in these cases was more abrupt than was usual in the disease, and nervous symptoms commonly attended. Attempts to control the fever by cold water often increased the difficulties and added enormously to the patient's suffering. Dr. Stengel then referred to a few striking cases.

Tuberculin Therapy.—Dr. H. Bascom Weaver of Asheville, N. C., read this paper. He believed the causes of failure of the tuberculin therapy in its first epoch, and the negative results that followed could be accounted for in two ways; the remedy, with few exceptions, was employed in a faulty manner, and the pathological findings were falsely interpreted by the profession. Too much tuberculin was given in too short a time, producing thereby a condition of excessive intoxication, and the organism was overwhelmed with toxins. In view of disastrous results there was little wonder at the revulsion of feeling against the remedy. The mode of action of tuberculin was not fully understood. The efficiency of tuberculin as a curative, as well as a diagnostic, agent had been proven. Trudeau stated that after sixteen years of treatment with the remedy he obtained permanent results in 18 to 25 per cent. of cases. Dr. Weaver believed that moderate reactions of 99-100° of fever, with slight physical symptoms, were conservative and did the patient good. The type of cases most desirable and that, in his experience, had yielded almost invariably good results, were (1) the incipient and moderately advanced classes, who were most afebrile, with a temperature ranging at times not over 100° and whose nutrition was good. (2) Uncomplicated first and second class with fever, although bacilli were found in the sputum. (3) Fibroid cases without febrile reactions. (4) Cases where fever was due solely to the toxin of bacilli and would not abate under rest and hygienic treatment; small tentative doses might do good. The following were the contraindications: (1) All third stage cases with mixed infection. (2) Second-stage cases with bad nutrition and mixed infection. (3) Hemoptysis. When hemorrhage occurred, it was a signal to stop the use of tuberculin temporarily until all signs of danger from hemorrhage had gone. (4) Heart disease. (5) Where the frequency and weakness of the pulse were present without any recognizable heart lesion. (6) Weak and greatly emaciated patients with a feeble and fast heart action. (7) All complications of internal organs, and nervous diseases. Alcohol and all intemperance must be sedulously avoided. The most important feature in tuberculin therapy, and one on which success or failure depended, was the question of dosage. The main principle was to so regulate the dose and interval that the maximum dose might be reached with as little disturbance as possible. The interval should be lengthened gradually. The treatment should last for from six months to two years. He said that at no time and under no circumstances did they consider tuberculin treatment superior to the dietetic, hygienic, and open-air treatment. It was only an adjunct.

Friday, June 5— Fourth Day.

Serum Treatment of Epidemic Cerebrospinal Meningitis.—Dr. Louis Williams Ladd of Cleveland read this paper. He said that the serum was first used systematically by him in a series of cases beginning early in April, 1907, at Castalia, Ohio, where an epidemic of this disease had created such havoc that half the population of the village of six hundred inhabitants had fled in terror. Between the months of January and April, eighteen cases of meningitis developed. Of these eighteen cases, twelve died and six recovered, a mortality of 66.7 per cent. and a recovery of 33.3 per cent. Serum was used in three cases. All of these recovered. Of the fifteen cases in which the serum was not used, twelve died and three recovered, or a mortality of 80 per cent. and a recovery of 20 per cent. Altogether the serum had been employed by him in thirty-two cases. Of these, one was still in the acute stage of the disease and could not be considered in the report. In thirty of the thirty-one cases the diagnosis was confirmed by finding the characteristic Gram negative diplococci in coverslip preparations, and in almost all cases the cultures were positive. That these were not mild cases but of marked severity was evidenced by the fact that when the serum was administered, seventeen of the cases were comatose, three unconscious and wildly delirious, and twelve cases were semi-comatose, or conscious with great irritability. Abstracts of the histories of each case were given. Eleven of the thirty-one cases died and twenty recovered, or a mortality of 35.5 per cent. and a recovery of 64.5 per cent. Twenty-four cases were treated ninety-six or less hours after the onset. Of these sixteen recovered and eight died, a mortality of 33.6 per cent. and a recovery of 66.7 per cent. Eighteen cases were seen seventy-two hours or less after the onset of symptoms. Fourteen of these recovered and four died, a mortality of 22.2 and recovery of 77.7 per cent. Thirteen cases were seen forty-eight hours or less after the onset of symptoms. Nine of these recovered and four died, a mortality of 30.7 per cent. and a recovery of 69.3 per cent. Five cases were seen twenty-eight hours or less after onset of symptoms. All of them recovered, or a percentage of 100 per cent. Eleven of the thirty-one cases developed in children under five years of age. Six of these recovered and five terminated fatally, a mortality of 45.5 per cent., and recovery of 54.5 per cent. The average duration of the disease in the remaining cases seen twenty-eight hours or less after the onset of symptoms, when treated with the serum, was twelve days; above twenty-eight hours and including forty-eight hours, nineteen days; above forty-eight hours and including seventy-two hours, forty-nine days. The temperature terminated by crisis in eleven cases and by lysis in nine cases. Examination of the spinal fluid in all cases showed the polymorphonuclear leucocytes to be the predominant cell with varying numbers of endothelial cells present.

The Serum Treatment of Meningitis.—Dr. Frank J. Slader and Lewellys F. Barker of Baltimore presented this paper. Since January 1 they had had at the Johns Hopkins Hospital 21 cases, compared to 33 cases in the previous nineteen years. Of the 33 cases treated simply by lumbar punctures in the previous years of the hospital, 21 died and 12 recovered, a mortality of 64 per cent. The mortality for the individual years varied from 43 per cent. to 100 per cent. With this they compared a mortality of 14 per cent. for the 21 cases treated with the antimeningitis serum in the past five months. Three of the 21 cases had died. One of the three was a fulminating case in the class of cases regarded by Flexner as beyond the reach of treatment. The second case had a complicating bronchopneumonia of both lungs upon admission, and died in forty-eight hours. The third case was a boy, twenty-nine months old, who received his first injection of serum on the fourteenth day of the disease when he was unconscious, having convulsions, and practically *in extremis*. He died of a respiratory paralysis in seventy-two hours, and even then two injections of serum had succeeded in clearing the spinal fluid of organisms and giving sterile

cultures. Twelve of the twenty-one cases were children under twelve years. Of these but one died, giving a mortality of 8 per cent. Seventy per cent. of the cases not treated by serum had complications, mainly bronchopneumonia; whereas, eight of the 21 serum cases (38 per cent.) suffered as follows: Otitis media, 3; pneumonia, 2; both otitis media and pneumonia, 1; arthritis, 1; acute myocarditis, 1. From this small experience they briefly summarized their impressions as follows: (1) All cases of meningitis in which the meningococcoccus was suspected should receive lumbar punctures and serum injection as early as possible. (2) The serum did no harm in cases not of meningococcal type. It might do good. (3) The course of the disease was changed by the serum. The long-drawn-out, chronic cases were not seen, and the terrible sequelæ, often worse than death, were rare. (4) As to the character of the serum, the rapidity with which the signs and symptoms disappeared suggested an antitoxic property; the positive chemiotaxis for polymorphonuclear leucocytes, and the promoted phagocytosis were the most definite and constant features; finally, the reduction in the number of diplococci, the change in their staining properties, and the loss of viability spoke for a bactericidal power, although it might be explained by the phagocytosis.

Pathology, Diagnosis and Treatment of So-Called Hodgkin's Disease.—Dr. Hugo A. Freund of Detroit read this paper. He said that it was Dr. Dorothy M. Reed who described accurately in 1902 the picture of this disease. It consisted simply of a fibrous increase of the reticulum of the lymph glands, a proliferation of the endothelium, the swollen cells lying in the fibrils; there was an increase in the number of lymphocytes. There were large, epithelioid, giant cells different from the giant cells occurring in tuberculosis and in most cases a number of mono- and polynuclear eosinophiles. The clinical picture that a case of Hodgkin's disease presented did not differ from the picture seen in a patient suffering from tuberculous adenitis or lymphosarcoma. The onset might be acute with diffuse soft swellings appearing rapidly along the lymphatic chains. In chronic cases a few moderately soft, discrete, movable painless swellings were felt first in the superficial cervical lymphatics on one or both sides of the neck. More rarely axillary nodes were first involved.

The Diagnostic Value of the Cutaneous and Conjunctival Tuberculin Reactions.—Dr. William Engelback and Dr. J. W. Shankland of St. Louis presented his communication and offered the following conclusions: I. The specificity of these reactions had as yet not been demonstrated, as proven by (1) experimental work on animals: (2) the presence of a positive reaction in nontuberculous conditions; (*a*) local conditions of the eye, trachoma, follicular conjunctivitis, etc.; (*b*) general conditions; clinically normal individuals, other diseases not tubercular (typhoid) controlled clinically and by autopsy; (3) the presence of a negative reaction in tuberculous cases; (*a*) miliary tuberculosis, tuberculous meningitis, and advanced pulmonary tuberculosis, etc.; (*b*) incipient and second stage tuberculosis controlled clinically and by autopsy; (4) the production of this reaction by other toxins, typhoid, etc., in tuberculous cases. II. The activity or extent of the lesion bore no definite relation to the degree or kind of reaction, for (1) one or both of these reactions had occurred in clinically normal individuals in an inconstant manner; (2) there was a marked variation of the occurrence of these reactions in different stages of clinical tuberculosis; and (3) there had been more definite control than the clinical findings of the relationship of the state of the lesion with the degree and kind of reaction. III. The conjunctival reaction was not free from danger for (1) nontuberculous lesions of the eye had been aggravated by it; (2) tuberculous lesions of the eye had been stimulated into activity by this reaction, and (3) general or constitutional symptoms had been produced by this instillation.

(*To be continued.*)

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

Board of Medical Examiners of the State of California.

San Francisco, April 7, 1908.

ANATOMY.

1. Describe the relation of intra and extracranial veins, locating five principal emissary veins.
2. What segments of the spinal cord supply nerves to the abdominal viscera?
3. What muscles attach to the greater and lesser tuberosities of the humerus and what tendon passes between these tuberosities?
4. Describe the topographical anatomy of the elbow.
5. (a) What bones can be palpated along the inner border of the foot? (b) What ligament does the keystone of the longitudinal arch rest upon?
6. Indicate what vertebræ mark the level of the following: (a) umbilicus, (b) end of spinal cord, (c) inferior angles of the scapulæ, (d) central tendon of the diaphragm, (e) inferior border of the pleuræ.
7. Describe the arrangement of the superficial inguinal lymphatic glands and indicate from what structures they receive lymphatic vessels.
8. What arteries supply the following structures and what arteries are they branches of: (a) thyroid gland, (b) mammary gland, (c) uterus, (d) testicle, (e) great toe?
9. What nerves innervate the following: (a) muscles of mastication, (b) muscles of expression, (c) sterno-cleido-mastoid, (d) muscles of the lingual region, (e) muscles of anterior femoral region, (f) skin on posterior surface of the thigh, (g) skin on inner surface of the arm, (h) skin over subcutaneous surface of the tibia, (i) tonsil, (j) meatus auditorius externus.
10. What are the relations and position of the pancreas?

HISTOLOGY.

1. Describe the histological structures and their relation to each other in a cross-section of the wall of the duodenum.
2. Describe the histological structure of the testes.
3. Describe the histological structure of a typical lymphatic gland.
4. Name the histological structures found in the eyelid.
5. Draw a diagram of a cross-section of a nerve trunk showing histological structures.
6. Describe the histological structure of the pancreas.
7. Describe the histological structure of the wall of the ureters.
8. Identify two specimens.
9. Identify two specimens.
10. Identify two specimens.

PHYSIOLOGY.

1. Discuss briefly the subject of animal heat.
2. Describe in detail the digestion of carbohydrates.
3. (a) Explain the production of the apex beat of the heart. (b) Give the cardiac nerve supply.
4. (a) In what regions of the chest may bronchial breathing be normally heard? (b) What is meant by Cheyne-Stokes respiration?
5. What is the physiological reason that the head, upper extremities, and abdomen are relatively larger in the new-born than in the adult?
6. (a) Give the specific gravity, chemical reaction, and the normal constituents of human urine. (b) Average quantity in 24 hours.
7. Give the distribution and function of the fourth cranial nerve.
8. Distinguish between cerebral and spinal paralyses in (a) Muscle tonus. (b) Nutrition of muscles. (c) Electrical reactions of muscles.
9. Where are the following centers: (a) Parturition, (b) auditory, (c) respiratory, (d) visual, (e) micturition.
10. Define: (a) Amnion, (b) corpus luteum, (c) myopia, (d) leucin, (e) eupnea, (f) erythrocyte, (g) hemolysin, (h) neuron, (i) dialysis, (j) lipase.

CHEMISTRY AND TOXICOLOGY.

1. Define (a) elements, (b) compounds, (c) synthesis, (d) analysis.
2. (a) Name and give formulæ of the compounds of nitrogen and hydrogen. (b) What two important elements found in the blood?
3. (a) In what is human milk richer than cows' milk? (b) In what poorer? (c) State the difference between egg albumin and serum albumin.
4. (a) Of what significance are hemin crystals? (b) What is the composition of hemoglobin?

5. (a) Injury to what principal organs would cause glycosuria? (b) Describe the chemistry of the stomach.
6. (a) What are carbohydrates? (b) What is the fat splitting ferment of the pancreatic juice? (c) Name five classes of proteids.
7. (a) Describe a quantitative test for sugar in the urine. (b) Give test for bile pigment in the urine. (c) What is the normal amount of urea excreted by the male in 24 hours?
8. Give classification of poisons with example of each.
9. (a) Describe Marsh's test for arsenic. (b) Is the quantity of saliva increased or decreased by mineral acids?
10. Symptoms: Intense burning pains from mouth to stomach, nausea, vomiting, diarrhea with bloody stools and swelling of the abdomen, lips and tongue white and shriveled, death in two days from collapse, crystalline substance found in the stomach. White soluble in water and gives black precipitate with H_2S. Name the poison and state what should have been the antidote.

BACTERIOLOGY.

1. Describe briefly and clearly the manufacture of serum agar. (a) State the sources of serum that may be used for this purpose. (b) Name three organisms to whose growth it is an essential.
2. Given a bacterial invasion, state exactly and in order the steps taken to prepare an homologous vaccine, including the standardization of same.
3. State the technique of a bacterial examination of milk. (a) What pathogenic organisms may be found? (b) How would you estimate the number per c.c.
4. What is tuberculin? (a) Name three varieties. (b) Describe Calmette's reaction.
5. Describe the organism of erysipelas. (a) How would you differentiate it from members of the same group?
6. Describe the gonococcus. (a) What organisms may be mistaken for the gonococcus? (b) Differentiate each.
7. Differentiate between pathogenic and nonpathogenic organisms. (a) Give four examples of each.
8. Describe the bacillus of tetanus. (a) Give its common habitat. (b) Name three toxins due to it.
9. Examination of two slides.
10. Examination of two slides.

PATHOLOGY.

1. In what disease conditions do we find acetonuria? Name the chemical bodies allied to acetone.
2. What conditions may produce a recrudescent fever in typhoid?
3. In tuberculous peritonitis, what are the sources of infection? What may be the postmortem appearance?
4. Describe the cerebrospinal fluid in epidemic meningitis; what are the portals of infection; and what is the gross pathology?
5. What are the causes of endarteritis; describe the successive microscopic stages; what changes in the brain may result from arteriosclerosis?
6. Name in the order of frequency the different lesions that may result from a gonococcus infection of the female genitourinary tract.
7. What are the typical anatomical findings, post mortem, in puerperal eclampsia?
8. Discuss the theories of the etiology of cancer.
9. Microscopic specimens.
10. Gross pathological specimens.

GENERAL DIAGNOSIS.

1. Differentiate cerebral hemorrhage, embolism, and thrombosis.
2. Describe bone lesions of syphilis.
3. Describe talipes equinus.
4. Describe uncinariasis.
5. Differentiate pyelitis and pyelonephritis.
6. Differentiate variola, varicella, rötheln, and scarlet fever.
7. Differentiate dislocation of the head of the femur from fracture of its neck.
8. Discuss thoracic aneurysm.
9. Differentiate inguinal hernia and enlarged inguinal gland.
10. Describe psoriasis.

OBSTETRICS.

1. (a) Describe the changes that take place in the mucous lining of the uterus preparing it for the reception of the fertilized ovum. (b) If it becomes attached what further changes take place? (c) If it passes without becoming attached what further changes occur?
2. At what period of pregnancy is an abortion or miscarriage most dangerous, and explain fully why.
3. Describe the conditions most likely to result in laceration of the cervix, and what remedies would you use, or what treatment would you employ to reduce the danger as much as possible?
4. Describe the clinical symptoms that would lead you to suspect tubal pregnancy during the early months of gestation.
5. Name five diseases that may be transmitted to the fetus *in utero*.
6. Describe fully how you would conduct a face presentation.
7. In breech presentations: (a) Are they more dangerous to the mother? If so, why? (b) Are they more dangerous to the child? If so, why? (c) Describe how you would conduct them to decrease the danger to either as much as possible.
8. Name ten drugs the mother should be instructed to avoid during lactation, and state fully how they endanger either the mother or child.
9. Describe fully the difference in the conditions calling for the use of oxytocics, and those calling for forceps.
10. Describe the conditions which would lead you to fear impending rupture of the uterus, and what would you do to prevent it?

GYNECOLOGY.

1. Give five causes of amenorrhea.
2. Give five causes of metrorrhagia.
3. Differentiate briefly between: pyosalpinx, tubal pregnancy, and parovarian cyst.
4. Differentiate briefly between: labial hematoma, labial hernia, labial hydrocele of the round ligament, and labial abscess.
5. Differentiate briefly between: hematosalpinx, hematometra, and hematocolpometra.
6. What is a rectocele, its most common cause and its treatment?
7. Give treatment of retroversion of the uterus in a severe case. Outline the operation.
8. Give a good reason for circumcising a woman and describe the operation.
9. What are the positions of the uterus in the three stages of prolapse?
10. Give diagnosis and treatment of urethral caruncle.

ANSWERS TO STATE BOARD EXAMINATION QUESTIONS.

BOARD OF MEDICAL EXAMINERS OF THE STATE OF CALIFORNIA.

San Francisco, April 7, 1908.

ANATOMY.

1. The *extracranial* veins are found in the superficial fascia above the aponeurosis. They communicate with the *intracranial* venous sinuses of the dura in several ways: (1) By the emissary veins; (2) by the angular and supraorbital veins anastomosing with the ophthalmic vein, which opens into the cavernous sinus; (3) by the diploic veins.
Five principal emissary veins: (1) A vein passing through the mastoid foramen, connecting the lateral sinus with the occipital and posterior auricular veins; (2) a vein passing through the foramen cecum, connecting the superior longitudinal sinus with the mucous membrane of the nose; (3) a vein passing through the parietal foramen, connecting the superior longitudinal sinus with the veins of the scalp; (4) a vein passing through the posterior condyloid foramen, connecting the lateral sinus with the deep veins of the neck; (5) small veins passing through the foramen ovale, connecting the cavernous sinus with the pharyngeal and pterygoid veins.
2. The abdominal viscera receive their nerve supply from the sixth dorsal to the first lumbar segment of the spinal cord.
3. To the greater tuberosity of the humerus are attached: Supraspinatus, infraspinatus, and teres minor muscles. To the lesser tuberosity is attached the subscapularis. Between these tuberosities there passes the long tendon of the biceps.
5. (*a*) The bones that can be palpated along the inner border of the foot are: Os calcis, internal malleolus, scaphoid, internal cuneiform, first metatarsal, sesamoid bones of the great toe.
(*b*) The astragalus is the keystone of the longitudinal arch of the foot, and it rests upon the inferior calcaneoscaphoid ligament.
6. (*a*) The *umbilicus* is opposite the fibrocartilaginous disc between the third and fourth lumbar vertebræ.
(*b*) The *end of the spinal cord* is opposite the lower edge of the body of the first lumbar vertebra.
(*c*) The *inferior angles of the scapulæ* are opposite the spine of the seventh dorsal vertebra.

(*d*) The *central tendon of the diaphragm* is opposite the spine of the eighth dorsal vertebra.

(*e*) The *inferior border of the pleuræ* is opposite the spine of the twelfth dorsal vertebra.

7. The superficial inguinal lymphatic glands are grouped along the lower edge of Poupart's ligament; they are flattened and ovoid in shape, and about half a dozen in number.

They receive lymphatic vessels from: part of the thigh, the buttock, skin of penis and scrotum or vulva, and from the superficial lymphatics of the abdomen below the umbilicus.

8.

	Arterial Supply.	*Branch of.*
(*a*) Thyroid gland....	1. Superior thyroid.	1. External carotid.
	2. Inferior thyroid.	2. Thyroid axis.
	3. Thyroidea ima (sometimes).	3. Innominate, or arch of aorta.
(*b*) Mammary gland....	1. Perforating branches.	1. Internal mammary.
	2. Long thoracic.	2. Axillary.
	3. Anterior intercostals.	3. Internal mammary.
	4. Intercostals.	4. Thoracic aorta.
(*c*) Uterus....	1. Uterine.	1. Internal iliac.
	2. Ovarian.	2. Abdominal aorta.
(*d*) Testicle...	1. Spermatic.	1. Abdominal aorta.
	2. Artery of vas deferens (sometimes).	2. Superior vesical.
(*e*) Great toe..	1. Dorsal digitals.	1. Dorsalis hallucis.
	2. Princeps hallucis.	2. Communicating of dorsalis pedis.

9

	Innervated by—
(*a*) Muscles of mastication.	(*a*) Inferior maxillary division of trigeminus.
(*b*) Muscles of expression.	(*b*) Facial.
(*c*) Sterno-cleido-mastoid..	(*c*) Spinal accessory.
(*d*) Muscles of lingual region.....	(*d*) Hypoglossal.
(*e*) Muscles of anterior femoral region.....	(*e*) Anterior crural.
(*f*) Skin on posterior surface of thigh.....	(*f*) Small sciatic and external cutaneous.
(*g*) Skin on inner surface of arm.....	(*g*) Internal cutaneous and lesser internal cutaneous.
(*h*) Skin over subcutaneous surface of tibia.	(*h*) Internal saphenous.
(*i*) Tonsil.....	(*i*) Glossopharyngeal and vagus.
(*j*) Meatus auditorius externus.....	(*j*) Inferior maxillary division of trigeminus, and vagus.

HISTOLOGY.

4. The histological structures found in the eyelid are: Skin, areolar tissue, orbicularis palpebrarum, palpebral ligament, levator palpebræ, tarsal cartilage, Meibomian glands, lashes, sebaceous follicles, and conjunctiva.

PHYSIOLOGY.

1. The heat of the body varies very little in health; it is maintained at a temperature of about 98° to 99° F.

The heat of the body is *maintained* by the thermotactic centers in the brain and cord keeping an equilibrium between the heat gained or produced in the body and the heat lost. Heat is *gained* to the body by (1) the muscles, during contraction; (2) the secreting glands; (3) the brain, during mental activity; and (4) by the ingestion of food and hot liquids.

Heat is *lost* to the body by (1) the skin, through evaporation, radiation, and conduction; (2) the lungs; and (3) the excretions (feces and urine).

2. (*a*) *Bronchial breathing* is normally heard over the trachea, just above the suprasternal notch, also over the primary bronchi.

(*b*) *Cheyne-Stokes respiration* is a condition in which the respirations gradually increase in volume and rapidity until they reach a climax, when they gradually subside, and finally cease for from ten to forty seconds, when the same cycle begins again.

5. The head, upper extremities, and abdomen are relatively larger in the new-born child than in the adult, because: (1) Most of the blood of the umbilical vein goes through the liver before reaching the inferior vena cava; (2) most of the pure blood is distributed by the branches of the arch of the aorta to the head and upper extremities. The better blood supply of these parts causes their better growth and development.

6. (*a*) The specific gravity of normal urine is from about 1015 to 1025; its chemical reaction is acid. The normal constituents of urine are: Water urea, uric acid, urates, hippuric acid, kreatinin, xanthin, hypoxanthin; sulphates, chlorides, and phosphates of sodium and potassium; phosphates of magnesium and calcium; nitrogen and carbon dioxide.

(*b*) The average quantity voided in 24 hours is about fifty ounces.

7. The fourth cranial nerve is distributed to the superior oblique muscle of the eye; it is the motor nerve of this muscle.

8.

	Cerebral Paralysis.	*Spinal Paralysis.*
(*a*) Muscle tonus.	Spastic; may be contractures.	Flaccid.
(*b*) Nutrition of muscle.....	Normal, or slight atrophy.	Marked atrophy.
(*c*) Electrical reaction.....	Normal.	Little or no response to faradic current; partial or complete reaction of degeneration to galvanic current.

9. (*a*) The center for parturition is in the lumbar region of the spinal cord; (*b*) auditory center is in the superior temporosphenoidal convolution of the cerebrum; (*c*) respiratory center is in the floor of the fourth ventricle; (*d*) visual center is in the occipital lobe; (*e*) center for micturition is in the lumbar region of the spinal cord.

10. (*a*) *Amnion* is the innermost of the fetal membranes.

(*b*) *Corpus luteum* is a yellow body found in the ovary at the site where a Graafian follicle has discharged its ovum.

(*c*) *Myopia* is a condition in which the anteroposterior axis of the eye is abnormally long, and parallel rays are focused in front of the retina.

(*d*) *Leucin* is a crystalline substance found in several tissues of the body; in the liver it is converted into urea; it is also found in the urine; its chemical name is amidocaproic acid.

(*e*) *Eupnœa* is easy or normal respiration.

(*f*) *Erythrocyte* is a red or colored blood corpuscle.

(*g*) *Hemolysin* is "a substance produced in the body of one species of animal by the introduction of red blood-corpuscles derived from the body of another species. It is capable of dissolving the red blood-corpuscles of the animal species from which the blood was obtained." (Gould.)

(*h*) *Neuron* is the unit of the nervous system; it consists of a nerve-cell with its processes and terminations.

(*i*) *Dialysis* is the process of separating substances from a mixture by placing the latter in a vessel with porous walls and immersing it in water, when the more diffusible substance passes through the porous wall.

(*j*) *Lipase* is a fat-splitting enzyme, found in the pancreatic juice and elsewhere; it has a reversible action.

CHEMISTRY AND TOXICOLOGY.

1. (*a*) *Elements* are substances which cannot, by any known means, be split up into two or more other kinds of substance.

(*b*) *Compounds* are substances made up of two or more elements chemically united, in definite proportions.

(*c*) *Synthesis* is the formation of compounds from elements or from simpler compounds.

(*d*) *Analysis* is the decomposition of a compound into simpler compounds or into elements.

2. (*a*) Compounds of Nitrogen and Hydrogen: Ammonia, NH_3; Hydrazine, N_2H_4; and Hydrazoic Acid, N_3H.

(*b*) Two important elements found in the blood: Oxygen and carbon.

3. (*a*) Human milk is richer than cow's milk in sugar.

(*b*) Human milk is poorer than cow's milk in proteids.

(*c*) "There are four distinct points of difference between the egg and the serum albumins: (1) Egg albumin is rapidly coagulated by alcohol; serum albumin but slowly. (2) Egg albumin is coagulated by ether; serum albumin is insoluble in ether, but is not actually coagulated. (3) Egg albumin is less soluble than serum albumin in nitric and in hydrochloric acids. (4) If egg albumin is injected into the circulation, or even if very large quantities of it are taken into the stomach, some of it may be excreted, apparently unchanged, in the urine, even in healthy individuals. This is not the case with serum albumin." (Pellew's *Manual of Chemistry.*)

4. (*a*) Hemin crystals are an absolute indication of the presence of blood-pigment.

(*b*) Hemoglobin is composed of the following elements: Carbon, hydrogen, oxygen, nitrogen, sulphur, and iron.

5. (*a*) *Permanent glycosuria* can be produced by injury to the floor of the fourth ventricle of the brain.

Transitory glycosuria has been observed after injury to the liver, the nervous system, and the cervical vertebræ.

6. (*a*) *Carbohydrates* were formerly defined as substances of unknown constitution, composed of carbon, hydrogen, and oxygen, the last two being in the proportion to form water.

(*b*) The fat-splitting ferment of the pancreatic juice is Steapsin.

(*c*) Five classes of proteids. Albumins, Globulins, Coagulated proteids, Derived proteids, and Proteoses.

7. (*a*) Method for the *quantitative estimation of sugar in urine*: *Fehling's method*: The solution is made as follows:

I.	Dissolve cupric sulphate	51.98 gm.
	in water to	500.00 c.c.
II.	Dissolve Rochelle salt	259.9 gm.
	in sodium hydroxide soln. sp. gr. 1.12 to	1,000 c.c.

(Piffard.)

When required for use, one volume of I. is to be mixed with two volumes of II. The copper contained in 10 c.c. of this mixture is precipitated completely, as cuprous oxide, by 0.05 gm. of glucose.

"To determine the quantity of sugar, place 10 c.c. of the mixed soln. in a flask of about 250 c.c. capacity, dilute with H_2O to about 30 c.c., and heat to boiling. On the other hand, the urine to be tested is diluted and thoroughly mixed with four volumes of H_2O if it be poor in sugar, or with nine volumes of H_2O if highly saccharine, and a burette filled with the mixture. When the Fehling soln. boils, add a few gtt. NH_4HO and then 5 c.c. of the urine from the burette, boil again, and continue the alternate addition of diluted urine and boiling of the mixture until the blue color is quite faint. Now add the diluted urine in quantities of 1 c.c. at a time, boiling after each addition until the blue color just disappears. Have ready a small filter, and, having filtered through it a few gtt. of the hot mixture, acidulate the filtrate with acetic acid, and add to it 1 gtt. soln. of potassium ferrocyanide. If a brownish tinge be produced, add another ½ c.c. of dil. urine to the flask, boil, and test with ferrocyanide as before. Continue this proceeding until no brown tinge is produced. The burette reading, taken at this point, gives the number of c.c. of dilute urine containing 0.05 gm. glucose, and this divided by 5 or 10, according as the urine was diluted with 4 or 9 volumes of H_2O, gives the number of c.c. of urine containing 0.05 gm. sugar. The number of c.c. urine passed in twenty-four hours divided by 20 times the number of c.c. containing 0.05 gm. glucose, gives the elimination of glucose in twenty-four hours in grams.

Example: Urine in 24 hours = 2,436 c.c.
Fehling's soln. used = 10 c.c.
Urine diluted with 4 vols. H_2O
Burette reading = 18.5 c.c.

$$\frac{18.5}{5} = 3.7 = \text{c.c. urine containing 0.05 gm. glucose.}$$

$$\frac{2{,}436}{3.7 \times 20} = 32.92 = \text{grams glucose eliminated in 24 hours."}$$

(Witthaus' *Urinalysis.*)

(*b*) *Test for bile pigment in the urine*: Put 3 c.c. HNO_3 in a test tube, add a piece of wood, and heat until the acid is yellow; cool. When cold, float some of the urine to be tested upon the surface of the acid. A green band is formed at the junction of the liquid, which gradually rises, and is succeeded from below by blue, reddish-violet, and yellow.

(*c*) The normal amount of urea excreted by a male in twenty-four hours is about an ounce to an ounce and a half.

8. Poisons may be classified as: 1. Mineral poisons, as arsenic; 2. Vegetable poisons, as oxalic acid; 3. Animal poisons, as ptomains; 4. Synthetic poisons, as chloral.

9. (*a*) *Marsh's test for Arsenic*: This test depends on the fact that arsenic hydride is formed when nascent hydrogen acts on a compound of arsenic:

$$H_3AsO_3 + 3H_2 = AsH_3 + 3H_2O.$$

A small flask fitted with thistle funnel and a delivery tube, as for the production of hydrogen, is used; pure zinc and hydrochloric acid are introduced, and after a short time the hydrogen is ignited. It is advisable to cover the flask with a cloth before igniting the gas, as an explosion may happen unless the air has all been driven out. If the materials are pure the hydrogen flame gives no deposit upon a piece of cold porcelain brought into it, but commercial zinc usually contains arsenic. When the purity of the gas is proved, a little solution of arsenite may be poured down the thistle funnel, which will produce a more rapid evolution of gas, and the flame will become larger and perceptibly colored. A piece of cold porcelain depressed upon the flame will be covered with a deposit of metallic arsenic. The films of arsenic are metallic looking in the thicker places, brownish near the edges; they are easily volatized by heat, and dissolve in solution of bleaching powder. A portion of the glass tube from which the gas is burnt should be heated to redness; the gas decomposes, and a deposit of arsenic appears on the tube, which may be identified in a similar way, or may be converted into crystals of oxide by cautious sublimation in an open tube. (Fisher's *Elementary Chemistry.*)

(*b*) The quantity of saliva is increased by mineral acids.

10. The symptoms given probably indicate poisoning by corrosive sublimate.

The antidote is white of egg in not too large a quantity, followed by an emetic.

PATHOLOGY.

1. *Acetonuria* is found in the following diseased conditions: Diabetes, prolonged fevers, puerperal eclampsia, pernicious vomiting of pregnancy, after chloroform anesthesia, carcinoma, inanition and wasting diseases, general paresis, melancholia, and epilepsy.

The chemical bodies allied to acetone are: Beta-oxybutyric acid, and diacetic acid.

2. The following conditions may produce a recrudescent fever in typhoid: Errors in diet, nervous excitement, and occasionally malaria.

3. In tuberculous peritonitis, *the sources of infection* are: The blood, the intestines, mesentery, Fallopian tubes, uterus, prostate, and epididymis.

The post-mortem appearances: Numerous tubercles in patches, or over the whole surface of the peritoneum, which is hyperemic; the omentum and mesentery are apt to be involved, and become thickened; there is an exudate, which may be serous, serofibrinous, or hemorrhagic; adhesions are often present, in chronic cases. The tubercles are yellowish or opaque, and may undergo caseation or suppuration.

4. In epidemic meningitis, the cerebrospinal fluid is apt to be turbid, may be bloody, and contains pus and the *Diplococcus intracellularis;* pneumonia diplococci, and other bacteria, chiefly streptococci and the various staphylocci have also been found.

The portal of infection is probably the nose, by inhalation.

Gross pathology: "The skull and dura mater are often abnormally vascular; the cerebral sinuses are much distended with blood. All the membranes of the brain are more or less congested; the arachnoid especially is vascular and opaque from inflammatory exudation—this opacity varies from slight milkiness to thick and dense deposits. The characteristic lesion is the whitish or greenish-yellow fibrinopurulent deposit found at the base of the brain; in many cases, however, it is not limited to the base, but extends up along the sulci to the vertex. This deposit varies somewhat with the duration of the disease; in cases which have lasted a week or two, it is abundant, yellowish or greenish; and the origins of the nerves seem to be buried in and compressed by the exudation. The brain substance itself is more vascular than normal, and there is some inflammatory infiltration of its superficial layers. The ventricles in the more acute cases contain turbid fluid, in the more prolonged they may be much distended by excess of clear cerebrospinal fluid. In the spinal cord the lesions are similar to those found in the brain and its membranes." (Quain's *Dictionary of Medicine.*)

6. As a result of gonococcus infection, a woman may suffer from: Urethritis, endocervicitis, vulvitis, infection of Bartholin's glands, vaginitis, endometritis, salpingitis, ovaritis, peritonitis, sterility, cystitis, proctitis.

7. In puerperal eclampsia, there may be found: The cortex of the kidney is pale and swollen, the epithelium shows cloudy swelling, degeneration, or necrosis; the ureters may be dilated; the liver is of normal size or smaller, and shows fatty degeneration and increase of

connective tissue; hemorrhages and infarcts, due to embolism or thrombosis, may also be present; the spleen shows changes similar to those in the liver.

GENERAL DIAGNOSIS.

1. *"Cerebral hemorrhage* occurs after the age of fifty-five, as a rule, with atheromatous arteries and an hypertrophied heart. The onset is sudden, with coma, during exertion or excitement. The temperature falls in an hour, and then rises, sometimes to 106°. Gradual recovery of consciousness takes place in from three to five days, with permanent hemiplegia.

"Cerebral embolism comes at any age, with heart disease or after childbirth. There is a sudden onset, without loss of consciousness or with slight mental confusion, or with rapid return to consciousness. The temperature does not fall, but may rise as high as 102°. Improvement occurs within twenty-four hours to a marked degree, but after three or four days the symptoms return. Monoplegia, hemiplegia, or aphasia may remain. Jacksonian epilepsy may develop if the lesion is cortical, involving a special center.

"Cerebral thrombosis occurs at any age, but chiefly in syphilitic persons and middle-aged men. There are usually premonitions. The onset is slower, without coma, but with dullness of the mind. The temperature does not fall, but may rise to 100°. The paralysis is similar to that observed in embolism.

GYNECOLOGY.

2. Five causes of metrorrhagia: Cancer of uterus, chronic metritis, fibroids, polypi, inversion of uterus.

5. In atresia of the vaginal orifice, when the menstrual blood collects in the vagina and cervix, the condition is called *Hematocolpometra;* when blood collects in the body of the uterus, it is called *Hematometra;* when blood collects in the tubes, it is called *Hematosalpinx.*

METHOD OF THE SPREAD OF YELLOW FEVER.*

BY COL. W. C. GORGAS, M.D.,
ANCON, CANAL ZONE.
CHIEF SANITARY OFFICER, ISTHMIAN CANAL COMMISSION.

I BELIEVE that, in nature, yellow fever is transmitted from one human being to another only by the bite of a female stegomyia mosquito, which has previously bitten another human being suffering from yellow fever. Since the epoch-making work of the Army Board, of which Reed was president, this has come to be universally accepted, and I do not intend to-night to discuss this phase of the question.

In Havana, Cuba, we had a large city—250,000 people, with a considerable nonimmune population, and fresh nonimmunes coming in at the rate of 20,000 a year, and children being born at the rate of 6,000 a year. The city had been infected continuously for one hundred and thirty years, and seemed to have the infecting material in every nook and corner.

We commenced work against yellow fever, along mosquito lines, in February, 1901, and the last case of yellow fever occurred in the city in September of that year; that is, it took us about eight months to get rid of fever in the city.

The general plan of our mosquito anti-yellow fever work was arranged under three general heads. We endeavored in every possible way (1) to prevent the breeding of stegomyia mosquitos, (2) to destroy the stegomyia mosquitos that had become infected, and (3) to prevent mosquitos becoming infected by protecting and caring for the sick so that they could not be bitten by the insects.

To prevent the breeding of mosquitos we divided the city into districts, put each district under the charge of an inspector, who got around to every house in his district once a month, and saw that all breeding places were destroyed.

To destroy infected mosquitos we fumigated with pyrethrum, or sulphur, every house in which a case of yellow fever was reported, and also fumigated all the houses contiguous to the infected one.

To prevent the infection of fresh mosquitos we moved all the yellow fever patients to screened hospital wards, or, if they preferred, screened the house in which they were sick.

The prompt success with which these measures was met I, at the time, attributed principally to the measures taken to destroy infected mosquitos, and to the measures to prevent fresh mosquitos from becoming infected. And this seemed to be the general belief, also, of most of those engaged in the work.

*Read before the Canal Zone Medical Association, Wednesday, April 15, 1908.

I conceived that necessarily a considerable number of infected mosquitos must escape from every fumigation, and it was always more or less a mystery to me why, with some infected mosquitos in all parts of the city, and nonimmune adults and children coming in at the rate of 25,000 a year, we did not continue to have yellow fever. Dr. Chaille and his followers—Guiteras and others—explained the immunity of natives in an infected locality as due to the fact that they have yellow fever in a mild form while infants and children. It seemed that if this were the case we should be having yellow fever at the rate of 6,000 cases yearly in Havana; that these cases would all be infecting mosquitos, and we had taken no measures whatever toward destroying the mosquitos that had been infected by these 6,000 yellow fever children. I thought that the results we obtained in Havana were due to the destruction of the infected mosquitos and to the preventing fresh mosquitos from becoming infected. If 6,000 children were having the fever every year in Havana I could see that our methods destroyed none of the mosquitos that were infected by these children, nor did they prevent fresh mosquitos from becoming infected by them. I, therefore, did not accept Dr. Chaille's explanation of native immunity, though I could see that it was a fact that the native Havanese was immune to yellow fever.

In 1904 I was sent to the Isthmus of Panama to take charge of the sanitary work here. The principal sanitary work at that time was to get rid of yellow fever. We put the same methods in operation which we had used in Havana. But we were on the Isthmus sixteen months before the last case of yellow fever occurred here. Now, what made the difference? Why did we get rid of yellow fever so much more promptly in Havana than in Panama? So far as yellow fever was concerned it seemed to me that it should have been accomplished certainly as promptly at Panama as it was at Havana. I was very much surprised at our want of prompt results at Panama, and have thought over the matter a great deal, and have satisfied myself that I understand the reason why one was apparently accomplished more quickly than the other—for after all the difference is only apparent, not real. We had been doing sanitary work in Havana for two years and a half before yellow fever disappeared, and while for the first two years this work was not being done on mosquito lines, a most excellent machine was being organized and perfected wherewith to carry through the work when the real cause of yellow fever was discovered.

In February, 1901, in Havana, the machine was all perfected, and everything ready, and all that I had to do was to give the necessary orders. In Panama the machine had to be built up from the bottom, and, for the first year, giving orders was of no more use than whistling.

Take a city such as Panama, in which normally

all the conditions are perfect for the perpetuation of yellow fever. Under these conditions, we will say we have one hundred stegomyias to the square yard. When a case of yellow fever occurs it is always bitten by mosquitos during the infective period, and, therefore, always leaves a number of infected stegomyia mosquitos which can convey the disease to nonimmunes present. This has been the mosquito condition of Panama since the world began. Now, if we reduce those mosquitos to fifty to the square yard. the yellow fever case will still be bitten, but not by so many mosquitos, and therefore there will not be so many infected mosquitos left. We would still have yellow fever if nonimmunes were present, but not so extensively. We reduce them still further to twenty-five. A smaller number of stegomyias bite the yellow fever patient, and we have fewer infected stegomyia mosquitos, but still some, and if nonimmunes are present, we have a slight epidemic. We go on still further with our work and reduce them to fifteen. The same results follow, only the epidemic is still milder as to numbers. We go on with our work and reduce them to 10 per cent. of the original number. The probabilities are that at this stage if we introduce the yellow fever patient the patient is not bitten, we get no infected mosquitos, and yellow fever abruptly disappears.

While it is possible with ten mosquitos to the square yard for one mosquito to become infected and give yellow fever to some other nonimmune in the house, it is not probable that this second yellow fever case will infect a second stegomyia. I am inclined to believe that a certain number of stegomyia mosquitos are necessary for the propagation of yellow fever, and ordinarily in yellow fever countries this number is largely exceeded; that your work goes on reducing the number without showing much results; and that, after awhile, your work reduces the number below this spreading point when yellow fever abruptly ceases. Now keep your mosquitos below this number, which we will call the yellow fever point, and no matter how many nonimmunes or how many cases of yellow fever you introduce, yellow fever cannot spread.

Take Havana in September, 1901. There were still stegomyia mosquitos in the city—the inspectors showed them as being present in considerable numbers every day. There were a large number of nonimmunes—over 50,000 at least—and in the preceding months quite a number of known cases of yellow fever; if Chaille's theory is true, there were a still larger number of Cuban children having yellow fever. Yet yellow fever not only did not spread, but disappeared.

Take Panama in December, 1905. There were stegomyia mosquitos, nonimmunes, and yellow fever sick all present, yet the same results came about—yellow fever not only did not spread, but disappeared. I think the reason is that while stegomyias were present they had fallen below the yellow fever point.

This theory, it seems to me, accords more with the facts as you meet them. The destruction of infected mosquitos and isolation of the sick, if carried out to theoretical perfection, might get rid of yellow fever, if the adult nonimmune population were the only people concerned, but if at the same time we have 6,000 children yearly having yellow fever, who are never reported, and not looked after in any way, the work among the adult nonimmunes would not be enough to affect the epidemic in any way. On the other hand, if the number of stegomyia mosquitos were reduced below the yellow fever point, it would not make any difference how many cases of yellow fever we introduced, or how many nonimmunes we had present, the disease would not spread.

When we came to Panama we had to build up a sanitary organization, and had great difficulty in getting supplies and the necessary authority for doing yellow fever work. But believing that the destruction of infected mosquitos and the prevention of mosquitos becoming infected were the essentials in yellow fever work, we concentrated all our energies on this phase of the work, and carried out this part of the mosquito work during the year 1904 just about as thoroughly as we had in Havana, but with no results whatever. As our nonimmunes increased yellow fever increased, and by the spring of 1905 we were having a good deal of yellow fever. But our organization became gradually perfected, supplies came in, the authority of the sanitary department was increased, and the stegomyia work was pushed, and by September, 1905, the stegomyia had been reduced below the yellow fever point and yellow fever disappeared.

The fumigations in Panama were much more extensive than they had been in Havana. In addition to fumigating the infected houses and all contiguous houses we went over the city three different times during the spring and summer of 1905, fumigating every house within its limits, yet yellow fever continued to increase.

I doubt if it is possible under any sanitary organization to do away with the stegomyia mosquito altogether, but it is very possible, as shown by the results of sanitary work, to reduce them below the yellow fever point. If your sanitary work is so organized that you can feel reasonably sure of keeping your stegomyias below this point, then you need have no fear of letting yellow fever cases come in, because even when they are admitted the disease cannot spread. Get your locality in this condition, and you could then do away with your quarantines, and thus grant great freedom to commerce.

I am inclined to think that now at Panama all that is necessary, as far as yellow fever is concerned, is to keep the stegomyia work so organized that we are sure in Panama and Colon of keeping the stegomyias below the yellow fever point. In combating the disease I would not advocate doing away with the other methods. It is very evident, theoretically, and Reed shows in his work, practical, that you could put half a dozen infected stegomyias in a room, and every nonimmune who slept in that room afterwards would develop yellow fever. You could fumigate that room with sulphur, kill the infected stegomyia mosquitos, and nonimmunes could afterwards sleep there with perfect safety. This is an illustration of what fumigation can do under certain peculiarly favorable conditions.

In the yellow fever wards at Ancon during 1905 all the doctors and nurses were nonimmunes. They were in the wards day and night where there were always some yellow fever cases, yet none of them contracted the disease. These wards were so screened and cared for that no stegomyia mosquitos could get at the patients so as to become infected.

But what I wish to emphasize in this paper is the fact that a certain proportion of stegomyia mosquitos in a locality is necessary for the spread of yellow fever; that if the number of stegomyia mosquitos remain above this yellow fever point we will continue to have yellow fever as long as we have nonimmunes present, no matter how much we fumigate or how carefully we isolate the sick, and

I advance Panama in 1905 as an illustration of this phase of the proposition. I think it is impossible to fumigate and isolate the sick more extensively or carefully than was done in Panama in 1905. If the stegomyias are reduced below the yellow fever point we can introduce yellow fever to any extent and nonimmunes in any number and yellow fever will not spread. In proof of this phase of the proposition I advance Havana in 1901 and Panama in 1905 as illustrations.

This, it seems to me, gives a reasonable explanation for the disappearance of yellow fever from Philadelphia, New York, Boston, and Quebec before we knew of its propagation by mosquitos. Take a city such as Philadelphia. The stegomyia is not found there normally, but, one hundred years ago, when Philadelphia was subject to yellow fever, we had numerous wells and cisterns as receptacles for storing water. Ships were constantly coming in from stegomyia regions and introducing the mosquito. Nearly every summer, no doubt, they were brought in and propagated there. When they had bred sufficiently to be above the yellow fever point over any considerable area, and yellow fever was introduced, we had an epidemic. Nowadays they have a piped water supply and there are very few breeding places. The communication with stegomyia regions is almost entirely by steamer, and few mosquitos are carried by steamers as compared with the old sailing vessels, and now there are no means of propagating mosquitos, so that when a case is introduced, even if there should happen to be a few stegomyias around, they are not in sufficient numbers to be above the yellow fever point, and the disease does not spread.

AN INTRADURAL TUMOR OF THE OPTIC NERVE REMOVED BY THE KRONLEIN METHOD.

By FRANK VAN FLEET, M.D.,

NEW YORK.

[SURGEON TO THE MANHATTAN EYE, EAR, AND THROAT HOSPITAL.

S. B., a girl aged fourteen years, small for her age but apparently healthy. Her family history is good in every particular, so far as can be ascertained.

The patient has always been a healthy girl, and has never had any serious sickness. She began menstruating when twelve years old, and has always had rather severe abdominal pains at these periods, but other than this there has never been anything unusual about them. She never had an injury of any kind that can be recalled; in fact, she has been unusually healthy and fortunate in this respect.

About two months before presenting herself for treatment, or about September, 1907, it was noticed that her left eye was slightly crossed and more prominent than the right. Then the vision in this eye began to fail until it became blind. No pain was associated with the condition, which possibly would not have been noticed but for the unusual prominence of the eye.

I saw the patient for the first time December 5, 1907, and noted the following: There was marked exophthalmus of the left eye. The mortality was not impaired and there did not appear to be any strabismus, which the patient declared was present at first. The pupil was moderately dilated and did not react to light. The cornea and media were clear, the optic nerve was dead white, but the retinal vessels seemed not to be diminished in size; if anything they seemed rather enlarged. The fundus of the eye, toward the macular region and also below the optic nerve, seemed to bulge forward, being seen at these points with plus six diopters, the rest of the fundus being seen with the aperture. The retina also had a peculiar striated appearance over these elevated parts.

The eye seemed to be pushed directly forward, and efforts to push it backward gave to the fingers the impression that there was some solid resisting substance back of it.

Pressure caused no pain. Vision was nil.

The right eye was normal in all respects except that vision was only about two-thirds, without apparent cause.

The patient was admitted to the Manhattan Eye, Ear, and Throat Hospital.

A radiograph by Dr. Edwin G. Zabriskie revealed no difference in the appearance of the two orbits, the picture being clear enough to reveal any difference which might have existed. Examination of the throat, nose, and accessory sinuses at different times, by Dr. Lewis A. Coffin and Dr. Thomas J. Harris, revealed nothing abnormal. The urine was of low specific gravity, 1010, no albumin, no casts, no sugar, no deposit, normal indican.

Blood examination: Erythrocytes, 4,532,000; leucocytes, 7,777.

FIG. 1.—Gross specimen, life size (slightly shrunken in hardening.)

Differential count: Large mononuclear lymphocytes, 12.12 per cent.; small mononuclear lymphocytes, 12.12 per cent.; polynuclear neuthrophiles, 75.75 per cent.

Physical examination by Dr. Herbert W. Wilcox revealed nothing abnormal. On admission to the hospital the patient's temperature was 99.5°, and fell in the morning to 98°; and kept rising and falling about one degree higher in the evening until the time of the operation.

On December 19, 1907, the patient was prepared for the Kronlein operation. An incision was made, starting in the temporal region of the left side, continuing toward the left eye to a point about 5 mm. from the outer canthus, and thence downward and outward to the center of the zygoma, forming a semicircular incision with its convexity toward the eye. This incision was extended downward through the tissue to the periosteum, and the tissues thus incised were dissected back to the extremities of the cutaneous incisions.

The periosteum thus exposed was incised over the outer orbital ridge, and beginning here this covering was separated from the bone forming the outer wall of the orbit down to the apex. A wedge-shaped piece of the exposed bone forming this wall, its base in the orbital ridge and tapering down toward the apex of the orbit, was cut out with a chisel. This piece of bone when its separation was completed, with its outer periosteal covering still in-

tact, was turned outward, thus forming a bone flap. The periosteum of the orbit, which had been separated from the bone, was then divided vertically, the two portions were drawn aside with sutures passed through them, and the cavity of the orbit was exposed.

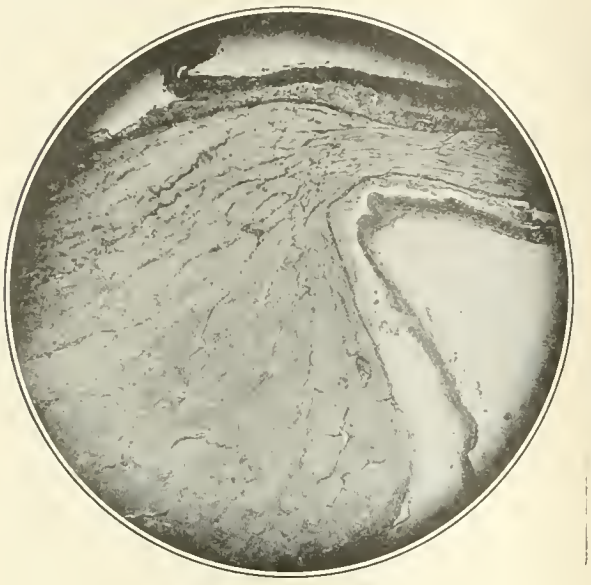

Fig. 2.—Section of growth at end nearest the globe. X10.

The finger passed into the orbital cavity through this opening came in contact with a mass occupying the entire space back of the globe, entirely surrounding the optic nerve, but not adherent to the bony walls or to the globe. With scissors the nerve was divided between the tumor and the eyeball and the mass drawn forward with a sharp tenaculum, the insertion of which into the mass allowed a quantity of fluid to escape, which materially diminished the size of the growth. The mass was then drawn forward and separated from the nerve at the optic foramen as close to the bone as possible, with curved scissors guided by the index finger, and the whole of the growth occupying the orbit was removed.

The orbit was then douched with sterile water, the divided periosteum stitched with catgut, the bone flap replaced, and the outer and inner periosteal edges united in the same way.

The skin and other tissue of the outer flap were replaced and the external wound was closed with silk sutures. A dressing of aseptic gauze and a bandage were applied. The anesthetic used was ether, and the time consumed in the operation was two hours.

After-Treatment.—Because of the expected reaction following so great a traumatism, the dressing was removed the following day. The exophthalmus was greater than before the operation, with edema and swelling of the eyelids of both eyes, the bridge of the nose, and the face generally. There was no complaint of pain or distress on the part of the patient, so the dressing was renewed and reapplied as before.

On December 21, the swelling having increased, iced applications were resorted to, the eye being protected with rubber tissue.

December 23, the swelling of the eyelids and face was greatly increased, the exophthalmus was marked, and the eyelid was unable to cover the eye. The eyeball was fixed and immovable. There was marked chemosis, and the lower part of the cornea was infiltrated. The cutaneous wound was smooth and clean. To protect the cornea the upper lid was drawn down and held in place with strips of zinc-oxide plaster and the iced cloths were continued.

On December 26 the swelling had gradually decreased, but a small ulcer had appeared on the cornea. The cutaneous wound had healed by first intention.

On December 31 the lower portion of the cutaneous wound was slightly swollen and red, and on January 1, 1908, this swelling was incised and a pus cavity emptied, which did not seem to communicate with the orbit. Following this the patient made an easy recovery.

After the operation there was ptosis with complete ophthalmoplegia of this eye, and inability to wrinkle the forehead on this side. The ptosis persisted for nearly four weeks, until January 28, when it had almost entirely disappeared. On this date there was slight movement of the eyeball in all directions excepting inward. There was slight haziness of the cornea, but no conjunctival irritation. The external wound entirely healed. Inability to wrinkle the forehead still continues. The pupil is about 4 mm. in size, and does not respond to light. The fundus can be seen with the ophthalmoscope, and the retinal vessels are present and apparently about normal in size. There can be seen some pigmentation of the fundus, which was not present before the operation.

Vision in the right eye 20/15.

Pathological report by Dr. Edgar S. Thomson.—Macroscopic examination: The specimen is composed of 8 mm. of optic nerve running into the lower part of a pear-shaped neoplasm 24 mm. long and 17 mm. in diameter. The optic nerve is eccentrically situated near the infero-temporal part of the growth. At the opposite end the growth is incomplete, and leads one to fear that intracranial extension may have already taken place. There is a large, cyst-like cavity in the substance of the growth from which the fluid has escaped at the end which lay at the apex of the orbit. Grossly, the substance of the growth is soft and friable.

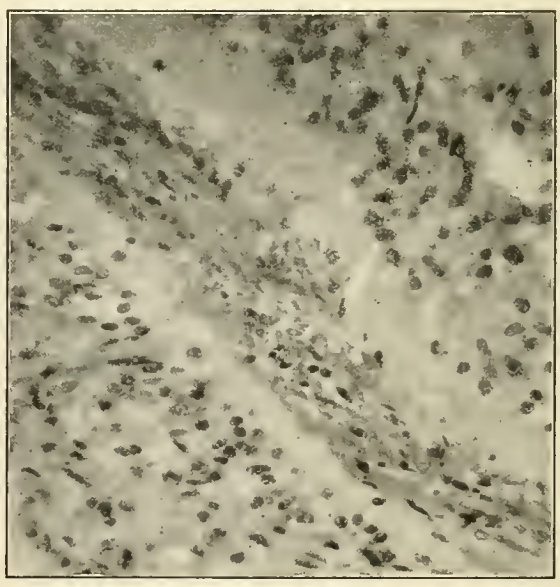

Fig. 3.—Section of growth near middle, showing arrangement of cells around a connective tissue band. X850.

The mass was sectioned somewhat obliquely, so as to divide the optic nerve and growth longitudinally.

Sections were stained by hematoxylin and eosin and by the Van Gieson method. Microscopically the growth is seen to spring from the nerve bundles, and to displace the pial processes more and

more the farther one gets from the globe. At the point of section near the eyeball and for a short distance back the nerve bundles show no change other than atrophy. Soon, however, they begin to enlarge and rapidly become ten times their width, displacing the pial processes irregularly and finally about the middle of the specimen become large, irregular, cellular masses.

There is considerable proliferation in the subdural space, which is usually observed in these cases. The growth itself is composed of irregularly shaped nuclei in large masses of neurogliar fibers. Blood-vessels are fairly numerous, and there is some evidence of endothelial proliferation, but this does not extend far from its origin, and it seems a fair presumption that most of the nuclei are neurogliar, especially as it is not known that proliferation of nerve fibers is possible. In the broken edges of the growth the neuroglia fibers can be plainly seen.

That the growth is locally malignant can hardly be doubted, but its further classification seems difficult. Unfortunately, it was not prepared for the specific neuroglia stain.

It seems best, under the circumstances, to call it an intradural tumor of the optic nerve, as has been done in cases of this character by Parsons, although the term "glioma" would probably not be inaccurate.

April 18, 1908. The patient was seen to-day. The movements of the eyelids are not impaired. The eyeball moves in all directions, but not freely inward, there being some divergence. The pupil is dilated and does not react. The retinal blood-vessels are mostly obliterated. There is extensive pigmentation of the retina. No pain or distress and no evidence of any return of the growth can be seen.

60 East Seventy-seventh Street.

INFLUENZA: ITS DIAGNOSIS FROM A MORPHOLOGICAL STANDPOINT IN STAINED SPECIMENS OF SPUTUM.*

By GEO. W. STILES, B.S., M.D.,

WASHINGTON, D. C.

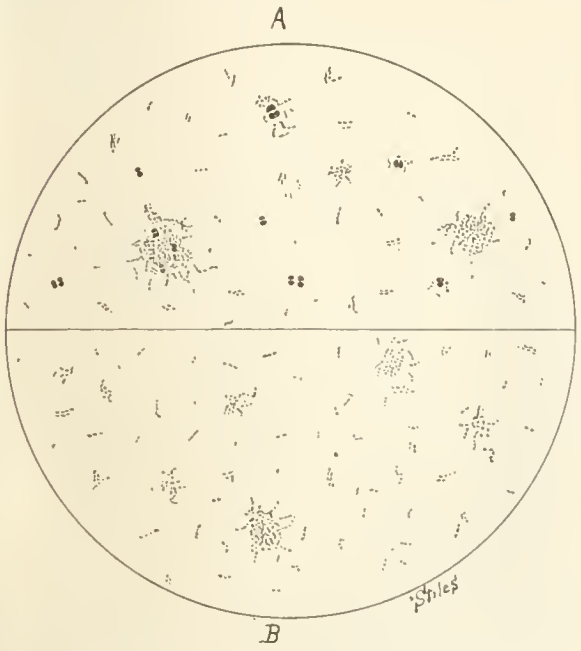
BACTERIOLOGICAL CHEMIST, BUREAU OF CHEMISTRY, U. S. DEPARTMENT OF AGRICULTURE.

During recent years much literature has been contributed concerning the symptoms, etiology, and treatment of influenza, but too little attention has been given its differential diagnosis from other diseases of a similar character which, at times, offers a very difficult problem for solution. This paper is presented with the hope that it may be of service to the busy practitioner who has but little time or opportunity to consult a microscope and who ordinarily would not have all of the necessary equipment to make a complete bacteriological examination of every specimen of sputum coming under his observation.

No extensive technical methods or unusual modes of procedure were planned in considering this subject, but the idea was simply to make an examination of a number of stained specimens of sputum from suspected cases of influenza in order to determine the reliability of diagnosing the disease from the morphological characters alone of the organism found in the sputum.

The period of investigation extended from February, 1907, to June of the same year, during which time a mild epidemic was sweeping over the city of Washington, manifesting itself in many ways, and often exhibiting unusual symptoms and various degrees of infection.

Technique.—Nearly all the specimens were received in sterile, half-ounce, stoppered shell vials and examined within a few hours after collection. A number of slides were prepared from each sample and stained after various formulæ. A platinum loop was found useful in removing small flocculent particles to the slide, and by means of a square cover-glass in a pair of forceps, or the end of another slide, thin, evenly distributed films were made without any difficulty. After drying in the air and gently fixing by heat, the slides were usually stained with alkaline methylene blue, and dilute solution of carbolfuchsin (about one part to 8 or 10 of water); the latter seemed to be the most satisfactory in my hands. If overstained, the excess of coloring matter was readily removed by washing with dilute alcohol. Proper staining is the important feature of the method to be considered. If overstained the organism occurring in masses, as is often the case, either fails to show distinctly, or does not show at all, and in order to show a distinct, clear cut outline, the staining must be of the proper degree of intensity. Ordinarily the organism stains with difficulty, but this may be overcome by gently applying heat to dilute stains for a few seconds. Pfeiffer's bacterium is Gram negative, hence this stain was used in connection with other stains in making the differential diagnosis.



A. Sputum showing Pfeiffer's Bacillus and Diplococci. B. Pfeiffer's Bacillus from Glycerin-Agar after 48 hours at 37°c. (X1000.)

From a number of the cases exhibiting typical symptoms, and showing practically pure strains of the organism in the sputum, the bacterium was isolated in pure culture by plating on serum agar, or 5 per cent. glycerin agar, and its biological characters studied. This was done in order to make certain that the organism seen in the smear preparations corresponded to that known as the Pfeiffer bacillus, or according to the recent classification of nonmotile rods, Pfeiffer's bacterium, the causative agent of influenza.

Biological Characters of Bacterium Influenza.—Isolated in pure culture February, 1907, from bron-

*Submitted as partial requirement for the degree of Ph.D. under the direction of Dr. Sterling Ruffin, Professor of Medicine, Medical Department, George Washington University.

chial secretion of a patient exhibiting typical symptoms of the respiratory type of influenza.

Morphology.—A very small, moderately plump rod, varying in dimensions from .2-.35 x .5-1.6 microns. two, or more times smaller than the average tubercle bacillus; occurring singly, or in pairs, end to end, often forming clusters of a dozen or more; occasionally showing distinct irregular chain formation of three to six or more elements. No capsule or spores demonstrated.

Biology.—An aërobic, nonmotile rod; grew best at about 37° C., feebly or not at all at lower temperatures. Growth, however, on all ordinary culture media was very feeble at best.

Staining.—Stained somewhat with difficulty. Gram negative. In my experience a dilute solution of Ziehl-Neelson solution (carbol-fuchsin 1 part, water 8 to 10 parts) seemed to give the most satisfactory results in bringing out the detail structure of the organisms; however, well-stained preparations were made with alkaline methylene blue and in some instances Wright's blood stain gave very satisfactory results in demonstrating the organism in leucocytes. Heat, gently applied, hastened the staining process. When overstained with carbol-fuchsin, washing with dilute alcohol removed the excess of coloring matter, often giving satisfactory results.

Behavior upon Culture Media.—Agar.—Serum agar, or 5 per cent. glycerin agar, offered a favorable medium. Growth was at first very slow; minute, glistening, almost transparent colonies were observed after twenty-four to thirty-six hours' incubation at 37.5° C. They generally remained distinctly separated, one from the other, and never attained very large dimensions. Older colonies became yellowish brown, while younger ones were grayish white in color. Initial cultures were best made upon media containing serum or hemoglobin compounds, however, subsequent transplantations were easily developed upon 5 per cent. glycerin agar. Upon plain agar even older generations grew poorly or not at all.

Peptonized Beef Broth.—In bouillon a faint turbidity slowly developed, gradually becoming clear, leaving a finely granular deposit at the bottom of the tube. No membrane or ring formation was observed. Cultures were kept alive in bouillon at ice-box temperature for over a month. In sputum kept under the same conditions the organism remained innocuous after three weeks.

Potato.—No growth occurred on plain or glycerinized potato.

Alkaline Litmus Milk.—At first unchanged, later the alkalinity slightly increased.

Dunham's Rosolic Acid.—Color increased to cherry red.

Sugar Media.—No gas production. Slight aërobic growth.

Gelatin, 10 per cent.—Fine granular, slowly developing colonies appeared after some days at about 20° C. No liquefaction of the medium occurred.

Indol.—Negative.

Pathogenesis.—When 0.5 c.c. of a forty-eight-hour bouillon culture was inoculated subcutaneously or intraperitoneally into guinea pigs and rabbits, no perceptible changes were observed, aside from slight malaise and drowsiness during the first or second days. Death did not occur within one month after inoculation. Larger doses were not tested.

The appended table of 100 cases deals with the case number, month of collecting the sample, diagnosis, presence of tubercle bacilli, streptococci, diplococci resembling pneumococci, miscellaneous bacteria, probable day of the disease, character of the sputum, and brief remarks on the symptomatology. The plus signs indicate positive diagnosis and the minus signs a negative diagnosis. Double plus signs indicate rich infection.

Symptomatology.—The following discussion of case histories is necessarily somewhat brief, since many of the patients remained under observation of the attending physician for a very limited period of time, and full information from each case was impracticable to obtain. However, in studying the notes thus presented, one will readily recognize resemblances of various commonly known types of the disease including the respiratory, gastrointestinal, nervous, rheumatic, febrile, and their many allied and varying manifestations. Aside from calling attention to a few histories representing the ordinary class of patients, there were a few others studied, which resembled what might be called the bronchial or tuberculous type.

Case XIV.—Patient 29 years old, male, general health good. Illness began suddenly February 17, 1907, with soreness and redness of pharynx, sneezing, general malaise, slight constipation, and anorexia. On February 18 had slight chilly sensation all day increasing in intensity at night. Muscular soreness general. Head slightly sore but no headache; a general tired out feeling. Occasionally cough. Temperature February 18, P. M., 102.4°; February 19, 100.2°. Feeling better on February 19, but still tired, sore, and exhausted. Muscular soreness somewhat improved.

Case XVI.—Mrs. W., aged about 30 years. Symptoms previously diagnosed as chronic tuberculosis. When first observed patient was found prostrate in bed where she had lain for several weeks. Treatment from former physician consisted largely of nourishing food and codliver oil containing creosote. Physical examination of the chest revealed symptoms not unlike those of advanced stages of tuberculosis. She expectorated large quantities of a greenish-yellow, mucopurulent sputum. Previous history negative for tuberculosis. Present attack began with "grippe" some months previous and she had been confined to bed since and seemed to grow worse under treatment. Repeated examination of the sputum for tubercle bacilli always gave negative results while nearly a pure species of Pfeiffer's bacterium was constantly present. These organisms were not only studied morphologically from stained specimens, but they were also isolated and examined in pure culture. Under appropriate treatment for influenza the cough subsided, the patient gained sufficient strength to sit up in bed, and within three weeks was able to be out on the street. Reports two or three months later showed further improvement, the woman at this time being apparently quite well.

Case XXVIII.—Mrs. R., age about 45. Acute symptoms began suddenly as a complication of chronic articular rheumatism. Very severe occipital headache, requiring opiates to relieve the extreme suffering. Marked pains in the limbs and back, nausea and vomiting very persistent during the whole of the first day. Moderate degree of fever with greatly accelerated pulse. Prostration and weakness extremely marked. Practically no cough with very scant bronchial secretion. Influenza symptoms responded quickly to proper therapeutic measures, with recovery after four days.

Case XLIII.—Thin, watery, frothy sputum. Second day of disease. Symptoms were coryza, aching pains general over the body, prostration, bronchitis. Many Pfeiffer's bacteria and diplococci.

SUMMARY

80 cases show positive results for presence of influenza bacteria.
11 " " negative " " " " " "
9 " " doubtful " " " " " "
3 " " T. B. present.
20 " " streptococci present.
36 " " diplococci present.
36 " " practically pure species influenza organisms.
24 " " " all P. B. and diplococci.
10 " " streptococci and diplococci in same smear.

Case LII.—Headache, sleepy feeling, sneezing, eyes painful to light, backache, constipation. Sputum examination showed practically a pure culture of Pfeiffer's bacterium.

Case LVI.—Began with chilly sensations, general drowsiness, depression, anorexia, sneezing, cough, aches and pains in arms and back. High fever accompanied by severe prostration. Rusty sputum expectorated for a day or two. Recovery uneventful.

Case LIX.—Began with torticolis, chilly sensations, sneezing, cough, aching arms and back. High fever, great prostration. Mucopurulent, rusty, blood-streaked sputum. Many diplococci and Pfeiffer's bacterium.

Case XCII.—Diagnosed at first as follicular tonsillitis by attending physician. Symptoms began with chilly sensations, general malaise, nausea, severe pains in occipital region and over one orbit. Temperature 102.4°. Stomach greatly deranged, prostration marked, throat reddened, with adherent, grayish white membrane on right side, not confined to the tonsils. First culture appeared suspicious for diphtheria; the second one, however, proved negative. Freshly stained smear preparations showed large numbers of organisms classed as *Bacterium influenzæ*. Small doses of phenacetin and acetanilid relieved the headache. Local applications of hydrogen peroxide and silver nitrate controlled the pharyngeal inflammation and membranous development. Recovery followed within two or three days.

Case XCIX.—A middle-aged plethoric woman, who was greatly annoyed for weeks by a distressing cough which seemed to be localized in one small area of the lung. Ordinary cough remedies had no effect, but under treatment for influenza her symptoms readily subsided. The influenza organism was demonstrated plentifully in the sputum. Tubercle bacilli negative.

In looking over the summary of the table it will be observed that 3 per cent. of the cases showed the presence of the tubercle bacillus, while at least four other cases, Nos. 75, 78, 91, and 99, gave clinical histories not unlike that of tuberculosis, but the specific bacillus was not to be found in the sputum; however, in each case large numbers of influenza organisms were present. This, of course, does not necessarily prove that the patient did not harbor the tubercle bacillus, yet on the other hand it tends to show that at least a few of the cases diagnosed as tuberculosis without careful and repeated sputum examinations, may really be due to the invasion of the influenza bacterium.

Since making the above study a number of other cases resembling influenza have come under my observation and information of undoubted value from the microscopical examination of the sputum has contributed much toward making a correct diagnosis, and in many instances indications of complications were observed before the advent of recognizable symptoms. For instance, a sputum containing large numbers of the influenza bacillus and pneumococci in the beginning of the disease almost invariably showed pneumonia or bronchitic symptoms soon after, generally differing in type from those cases showing only a pure species of influenza organisms. The presence of streptococci or other organisms in the sputum showing a mixed infection gives the physician a valuable clue in planning his course for future treatment.

Summary.—1. In view of the results obtained from this series of cases, I cannot too strongly emphasize the necessity of making routine microscopical examinations of sputum from cases manifesting general respiratory symptoms of disease. No matter what the previous diagnosis may have been from the symptomatology alone, further light on the condition of the patient may be had from a microscopical study of the sputum.

2. Valuable information may be obtained from a brief study of well-stained specimens of sputum from suspected or complicated cases of influenza.

3. A few cases resembling tuberculosis may be due to infection of influenza bacilli alone or to a mixed infection of the two organisms.

SEVERAL CASES ILLUSTRATING LIVER SYMPTOMS IN CARDIAC DISEASE.*

BY LOUIS FAUGÈRES BISHOP, A.M., M.D.,

NEW YORK.

CLINICAL PROFESSOR OF HEART AND CIRCULATORY DISEASES, FORDHAM UNIVERSITY SCHOOL OF MEDICINE, NEW YORK CITY; PHYSICIAN TO THE LINCOLN HOSPITAL.

THE three cardinal symptoms of heart disease are dyspnea, enlargement and tenderness of the liver, and dropsy. This statement may come as a surprise to those who have not been accustomed to make a distinction between the symptoms of heart

FIG. 1.—Case I. Enlargement and Tenderness of the Liver as a Result of Heart Disease. Sudden Death.

failure proper and the symptoms of more general conditions such as shock, arteriosclerosis, Bright's disease, and so on, in which the heart becomes secondarily involved. Thus there may exist great irregularities of the heart, but if there is no dyspnea,

*Read at a meeting of the Manhattan Medical Society, March 27, 1908.

no enlargement and tenderness of the liver, and no dropsy, the cardinal symptoms of heart disease are lacking.

Enlargement and tenderness of the liver is an important indication of the general disturbance of the circulation that results from failure of the heart.

Fig. 2.—Case III. Enlargement and Tenderness of the Liver in a Case of Mitral Stenosis, the Peripheral Paralysis Due to the Original Infection that Caused the Heart Lesion.

The venous stagnation results in swelling and tenderness of the liver and the liver affords in this way an important indication of the progress of cardiac disease. The tenderness is often greater in acute cardiac failure than in old cases. An enlargement of the liver during this condition may be considerable and this disturbance of the liver leads in some cases to a slight degree of jaundice. So valuable a symptom is tenderness and enlargement of the liver that, in picking out the heart cases in hasty hospital rounds when first on duty with upwards to a hundred patients to review in a short time, I have made it a practice to palpate the liver before using the stethoscope. In the absence of enlargement and tenderness of the liver, an urgent uncomplicated heart case has hardly ever been found, if the condition has existed several days.

Fig. 3.—Case V. Enlargement and Tenderness of the Liver Due to Broken Compensation. During the Attack.

A few typical cases that I have seen within the last six months are the following:

Case I.—Woman, fifty years old, whom I saw first on January 3, 1908. She had a cardiac history of long standing, but it had become worse lately. Physical examination revealed a very striking double mitral murmur. Her liver was considerably enlarged and tender, though her dropsy was not very great and her dyspnea not urgent. The evidence of venous stasis in the liver was so great that I considered the prognosis very bad. Her symptoms did not increase, but they did not improve, and she died suddenly six days later, on January 9, without any warning.

Case II.—A woman, forty-five years old, had several attacks of rheumatism with cardiac involvement and had suffered previously from great edema of the legs which had left her with a troublesome pressure neuritis that was very painful. She had a systolic murmur over the mitral area and there was a moderate enlargement and tenderness of the liver.

Case III.—A woman, thirty-six years old. Early in life had a very profound infection by diphtheria that had resulted in endocarditis and general neuritis. She gave a history of many years of cardiac suffering and showed the deformities of the extremities due to destruction of peripheral nerves. She had mitral stenosis of a very high degree of development and for the past six months had been going down hill so that on numerous occasions it had been necessary to remove the fluid from her chest to keep her from suffocating. When I first saw her her liver was large and exquisitely tender. By careful medication and hygienic measures the liver was reduced in size and was less painful for three months and the necessity for mechanical removal of fluid was obviated, thus showing the coincidence of the two symptoms. She later developed cerebral embolism and finally died from this cause.

Fig. 4.—Case V. Enlargement and Tenderness of the Liver Due to Broken Compensation. After Recovery.

Case IV.—A woman, seventy-four years old, had had high arterial tension for a number of years resulting finally in cardiac exhaustion. She had marked tenderness of the liver and great irritability of the stomach so that rectal feeding was necessary. On a suitable regimen and carefully selected medication the enlargement and tenderness of the liver disappeared and the functions of the stomach were restored. She has remained well, but under supervision, for six months.

Case V.—A man, forty-three years old, having had rheumatic endocarditis, had developed broken compensation, showed mitral stenosis and insufficiency, aortic stenosis and insufficiency, and tricuspid regurgitation. His liver was enormously congested and tender, and he was slightly jaundiced. He responded to treatment and made a good recovery. The illustrations herewith are from photographs showing him during and after his attack.

Case VI.—A patient, forty years old, with mit-

ral stenosis and insufficiency, showed tenderness of the liver.

Case VII.—A patient of seventy-one years, with fatty degeneration of the heart, showed tenderness of the liver.

Case VIII.—A woman, twenty-nine years old, with aortic stenosis and regurgitation and mitral insufficiency, suffering from profound cardiac cachexia, had enlargement and tenderness of the liver. Her condition did not change much under treatment.

The critical examination of cardiac cases shows that in true cardiac weakness liver symptoms are almost constant, and the mistake must not be made of diagnosing primary liver disease. I have not discussed the gastric symptoms which often go with the condition and which have often been mistaken for stomach disease.

54 West Fifty-fifth Street.

ADVERSE SUGGESTION.

By AUSTEN FOX RIGGS, M.D.,

NEW YORK.

ASSISTANT IN MEDICINE, COLLEGE OF PHYSICIANS AND SURGEONS, COLUMBIA UNIVERSITY.

Psychotherapy of late years has come gradually more and more to the front, until to-day it is a subject very widely talked of, but chiefly by the non-medical public. Physicians in the past, although apparently in no way doubting the validity of psychological laws, have, as a profession, made very little conscious and, therefore, intelligent use of the therapeutic opportunities they offer. There were notable and brilliant exceptions to this rule of negligence. Such pioneers as Braid of Manchester, Liébeault of Nancy, Azam of Bordeaux, and later Bernheim of Nancy and Charcot of Paris, in spite of the bitterest professional opposition, amounting at times to fanaticism, finally separated hypnotism from mesmerism, animal magnetism, etc., and laid the foundations of psychotherapy. But even now, psychology remains in the minds of the great majority of physicians as an interesting theoretical subject, and suggestion as an agent fit only for the hands of the specialist and of the hypnotist.

On the other hand, charlatanism has an important message for the medical profession. It has long realized the practical side of psychology, has applied its laws, and is even now able to point with pride to clinical results where the medical profession has failed. Mental healing, Christian Science, and other similar healing cults and systems, have suggestibility to thank for the number of cures that stand to their credit. They have accomplished in these cases, by an illegitimate use of suggestion, what the medical profession should have accomplished by its legitimate use. They have consciously and cleverly used (as well as abused) a therapeutic agent of which, as a matter of fact, successful physicians by their cheerful manner and encouraging words have made unconscious, unintelligent, haphazard use, and have likewise unconsciously and inadvertently misused for ages. The natural explanation of the tremendous popularity of the well nigh numberless "ists," "isms" and "paths" of the present day, is that patients find in them what they need but cannot get from orthodox sources. The physician who ignores the psychic element of disease is just as narrow as the Christian scientist who denies its physical existence.

That conscious, intelligent use of suggestion should be within the grasp of every physician, that it is his imperative duty to avail himself of its manifold benefits, and that above all he should avoid its unintelligent, unconscious misuse are facts which cannot be too strongly emphasized.

It needs hardly a moment's serious consideration to establish the gross inconsistency of treating human beings as though their minds and bodies were independent. The psychological law laid down by Professor William James years ago that "no mental modification ever occurs which is not accompanied or followed by a bodily change" is familiar to all. We all know that it is the mind, not the body, that suffers; that the patient is a suffering consciousness, not an insensate biochemical laboratory. That bodily ills cause mental disturbances and that mental disturbances cause bodily ills, are facts too well known to need demonstration. The concept of psychophysiological unity is the basis of enlightened monistic philosophy and it is the *only* concept which agrees with and is supported by the laws of nature. Indeed, I believe it would be hard to find an educated man, especially among physicians, nowadays, who would deny the validity of this basic truth. Yet in practice not a few physicians, in face of these facts, frequently treat the body as though it were independent of the mind, and the suffering patient as though he were a deranged mechanism or an ailing ameba.

A working knowledge of psychology is at least as important to the practical physician as is familiarity with the physiological action of drugs, for suggestibility is a universal characteristic, and the physician need not be a hypnotist nor the patient an hysteric for suggestion to be used to advantage. It is, however, essential that the physician should be conversant with the fundamental characteristics of the subconscious self which Sidis so well describes as the "highway of suggestion." Appreciation of its surpassing sensitiveness to suggestions, of its astonishing credulousness, of its tenacious memory, and above all, of its close association with all the organic functions, is one of the essentials of an efficient and intelligent use of suggestion. It is clear that to gain an appreciation of this sensitive and puissant subconsciousness and a knowledge of the ways and means of influencing it, one must acquire the fundamental principles of psychology.

In order to avoid confusion as to the meaning of "suggestion" and "suggestibility" I here quote Prof. Aug. Forel's definitions of these terms, which seem to me particularly clear and comprehensive and in accordance with which I use the words. "By suggestion one means the production of a dynamic change in the nervous system of a person, or of such functions which depend on his nervous system, by another person by means of calling forth representations (be they conceived or unconceived) that such a change is taking place, has taken place, or will take place."...."Suggestibility is the individual susceptibility toward suggestion."

Every-day life offers ample proof of how suggestible we all are. When the small boy sucks a lemon before the brass band and thereby causes salivation and puts the band out of business, the players offer unconscious tribute to suggestion. One has but to talk of fleas to cause many people to itch uncomfortably. Many individuals can be made to blush furiously, simply by being told that they are going to blush. The power of suggestion is again shown in the often remarkably complete therapeutic effect that a hypodermic injection of sterile water has, when unknown to the patient it is substituted for morphine. These familiar examples

of the rôle that suggestion plays in every-day life could be multiplied almost indefinitely were further proof necessary of the universal presence of suggestibility.

Let any physician meet one of his acquaintance who is in robust health; let him remark with sympathy upon his pallor, his tired and ill appearance, and then note the depressing effect; an effect which may influence every thought and action throughout the day. Let the same physician meet one who is really ailing; let him this time dwell with enthusiasm on the latter's youthful appearance, good color, and healthy look, and then note again the change in expression, the smile of satisfaction, the different step. Although these illustrations may seem trivial at the first glance, they, nevertheless, contain an indication of a power which may work strongly for good or strongly for evil, according to circumstances. Does the physician, in the instances just described, really make one patient ill and the other well, by mere words and manner? By no means. He does, however, in the first instance, produce a mild mental disorder accompanied by depression, during which all the bodily functions may be disturbed, and the individual even be rendered more susceptible to the inroad of disease. In the second instance he arouses in the patient feelings of self-confidence, encouragement, and hope, his bodily functions improve and he is thus actually strengthened in his fight against disease. Organic diseases cannot be cured by suggestion, but they can be helped by it; and the great number of diseases due to functional disturbances without organic change are usually capable of cure, largely through suggestion. In so far as truth will permit, patients should be filled with hope and encouragement, and they will then sleep better, digest better, think better, and get well more quickly. The truth and suggestion are not at variance; but the truth dressed in black may be an adverse suggestion of destructive force, whereas the same truth presented in more attractive guise may carry with it the very hope and cheer of which the patient stands most in need.

That suggestion is frequently employed quite unconsciously by most physicians in every-day medical life, according to the cheerfulness and hopefulness of their dispositions, is clear without much thought. That it would be employed to far greater advantage, and that important opportunities for its beneficial use would not so often be lost were every physician to equip himself for its intelligent use, is hardly in need of demonstration. But even if one does not realize the responsibility of making the most of a given therapeutic agent, surely there is little doubt that nobody can escape the responsibility of at least avoiding its misuse. As it is clearly impossible to do this without some knowledge of the subject, the study of psychology becomes a duty which no medical man can honestly overlook. I do not advocate that every physician should try to become an expert psychotherapist,—that would be manifestly impossible,—but it is my contention that he should have sufficient knowledge of psychology to take advantage of the manifold opportunities, presented in every-day experience, of using the suggestibility of his patients to their advantage, and that above all, he should be able to avoid counteracting his attempts at treatment (at times of actually neutralizing them), by inadvertent adverse suggestion.

To illustrate my meaning let me quote a few examples of what may be called adverse suggestion. They will, I think, prove not altogether unfamiliar types. In the first place, there is the gloomy individual who, by his supernaturally serious manner as well as by his every word, transmits his pessimism to every one he comes in contact with, but especially to those he intends to heal. The way he makes a physical examination, the way he looks at the tongue, the way he takes the pulse; each action adds its increment of adverse suggestion. The patient who before his visit was perhaps cheerful and confident, is now thrown into a state of cheerless apprehension, or at best is deeply impressed with the seriousness of all illness, and especially of his own malady. It is reasonable to suppose that this type of behavior is due to ignorance of the power of suggestion, rather than to disregard of the patient's weltare, and that a little knowledge of psychology would at once lead to reform.

The mechanical reiteration of some supposedly encouraging phrase such as "very good," or "first rate," used with the accompaniment of knitted brows and dubiously shaking head, is unconvincing and useless by way of suggestion; indeed, often most irritating in its irrelevancy. Manner and expression, as well as words, must be suited to the need of each individual patient, and to do this an elementary knowledge of psychology is as necessary as common sense.

The restless, evidently hurried, and patently overbusy physician who is always late for his appointments, who never sits down quietly by the patient's bed, who is manifestly worried over the flight of time, inevitably impresses the patient, perhaps with his own importance, but certainly with the patient's unimportance,—a suggestion clearly not calculated to fill the patient with the proper sense of comfort and reliance in his physician. There are better ways of economizing time than hurrying! One of our leading clinicians sharply criticised me on one occasion for having seemed hurried during a consultation. He said: "Don't ever make a visit on a patient without drawing up a chair and sitting down; standing and walking about the room are indicative of hurry and lack of interest on your part. That has a bad effect on the patient." Thus he gave me an important lesson in psychotherapy.

Fortunately the physician who thinks aloud while making his diagnosis is not very common, but he affords such an excellent example of the harm that adverse suggestion may do, that I venture to quote a case which has recently come to my notice. A lady who had what she thought was indigestion, sent for her physician. During his examination and the process of making his diagnosis he thought of and gave mumbling voice to, so many disconcerting possibilities and probabilities that when he finally "pronounced the case" to be simple indigestion it had little effect on the patient's conviction (for which he was entirely responsible), that something very serious was the matter. The patient in her distress demanded another opinion, and was finally reassured by another physician, but with the greatest difficulty. Yet such is the remarkable working of the human mind, that this patient, far from criticising her physician, commended him highly for his honesty in saying just what he thought, apparently entirely unconscious of the harm his "honesty" had done her; her confidence still unshaken. What a powerful therapeutic ally this same confidence might have been, had it been used, not abused!

Another way in which adverse suggestions are often inadvertently given, and I am convinced that it is the direct result of over-development of the scientific spirit of investigation, is that of putting the

patient through a maze of mechanical and laboratory procedures as a matter of routine. Organs that he has never before been conscious of possessing are ruthlessly and often quite uselessly dragged before the stern tribunal of the doctor's scientific spirit. The physician is so interested in his truly interesting tests, so anxious to get at the exact truth, that he forgets his patient as an individual. He does not realize that these tests, all of which are strange to the patient, and some of which are at least very disagreeable to him, are redolent of suggestion. They inevitably bring before the patient's mind, to a greater or less degree, the vast pathological possibilities inherent in him. Unchecked by any suggestion to the contrary, his imagination naturally does its full duty, and the last condition of that patient is worse than the first. There is no question as to the value of accurate diagnosis, and every help, whether bacteriological, chemical, or mechanical, should be called to our aid when necessary; but to put every patient through an elaborate system of clinical tests as a matter of routine cannot be too strongly deprecated. It is my conviction that no patient should be put through a single procedure, scientific or otherwise, that is not necessary to the clear understanding of his case, and that then the necessary tests should be made with every care to avoid unfavorable impressions—adverse suggestions. Indeed, in many cases I feel sure that the necessary tests may not only be shorn of their adverse suggestions, but may even be endowed with suggestions distinctly favorable to the patient. To do this a psychological as well as a physiological study of the individual case is absolutely essential. The following example, also taken from my own experience, I think will serve to illustrate my contention. It is, I feel sure, but one of a large number.

Mrs. L., for nearly a year wandered about from place to place in search of relief from what turned out finally to be autointoxication, with the not unusual complication of mental depression. After knocking about during this time from specialist to specialist, she was somewhat, though not much, worse. Various possible diagnoses had been submitted to her, none of them positive, all of them suggestive of dire possibilities. She was then persuaded to try a Western physician, well-known for his scientific and thorough work. The latter's assistant was sent with a bagful of apparatus to the sufferer's hotel; the apparatus was unpacked; it made a formidable display. A blood examination was made; blood pressure was ascertained by two different instruments; previously arranged for specimens of various excretions were accumulated. The better part of an hour was thus consumed, and the patient was duly, in fact, too thoroughly, impressed. Being a very intelligent woman and naturally an interested spectator of these proceedings, she asked the assistant the reason for each examination and what bearing it might have on her case. The assistant gladly, enthusiastically, explained each procedure and all the bearing it might have, not only on her case, but on various other cases. The patient said that when the assistant left, she felt as though none of her organs were above suspicion, and that a whole array of new possibilities had been set before her. She had been told that several days must elapse before the various examinations could be completed and the reports handed in. In the meantime her thoughts were busy, and, in the absence of any favorable suggestions, they were not of a pleasant character. All the deadly diseases associated in her mind with the various organs on trial passed in gloomy review before her. An office visit was arranged for. A physical examination was made; then more urine was examined. Her stomach was pumped out, and another blood pressure test was made. She was told it was all for diagnostic purposes, and not one word of favorable suggestion was used to counteract these depressing procedures. She felt that she was getting worse day by day. Adverse suggestion was doing its work. She grew more emotional; her depression became profound; her nights were more restless; her appetite disappeared; she was in a deplorable condition. More tests were made. Finally the whole verdict was in, it was—"neurasthenia." The patient would have been glad to believe it, but she could not. Adverse suggestion had done its work. Subconscious evidence was too strong. Science had reached the truth, but the patient was not the gainer; she on the contrary had been harmed, made worse. The cheerful assurance of ultimate health given her then had naturally very little effect on the now profound depression. Eliminative treatment had been instituted, with, however, the suggestion, unconsciously given by the physician but keenly appreciated by the patient, that no treatment was of much avail and that only time would effect a cure. She was then sent away to the country to get well. The next few months saw some slight physical improvement, but her mental condition remained about the same. She then fell into the hands of a doctor evidently thoroughly alive to the value of psychotherapy. This man studied her mental state as carefully as he did her physical condition. He treated the autointoxication as any intelligent physician would, but with this great difference,—he went at it with *assurance* and used every other favorable suggestion that could be brought to bear. The result was brilliant. Insomnia, which had been greatly increased by adverse suggestion, entirely disappeared, and long, restful nights succeeded each other. Disturbed functions were reestablished; consequently, appetite and nutrition immediately improved. There was a rapid disappearance of depression and a return of interest in matters other than the patient's bodily condition. Anyone will readily admit the very great gain to the patient in days spent in the hopeful anticipation of returning health, as compared with a life continuously poisoned by the constant thought of impending disaster. In a few weeks she was well.

The contrast presented by this case, between the effect of treatment with adverse suggestion and that of practically the same treatment with favorable suggestion, is, I think, sufficiently striking without further comment. Furthermore, the case is undoubtedly illustrative of a very large class.

Let me quote one other case which demonstrates the value of favorable suggestion: Mrs. H., who for twenty years or more had suffered from obstinate constipation in spite of hygienic, dietetic, and medicinal treatment, happened one day, while waiting, to pick up Dubois' "Psychic Treatment of Nervous Disorders" which was lying on my table. Glancing through the index she found that there was a chapter on constipation, her "bête noire." She read that chapter through. Many cases were described; the cases seemed, most of them, more severe than hers. She went home determined to try his system, and for this purpose she bought a copy of the book in order to follow his directions to the letter. She did exactly as he directs, and discarded her habitual drugs. Except for the first day or two, in which she had no very satisfactory results, she has since then until now, a period of four

months, had a normal movement every single morning, without any medication whatever. The system Dubois describes differs in no essential way, save for the lack of all drugs, from that which Mrs. H. had been following for years. She had risen every morning at a fixed hour, taken a glass of water on arising, had breakfasted at an equally fixed hour, and had gone to the toilet also at a fixed time. Besides, she had eaten quantities of fruits, taken a laxative every night, and had also taken plenty of water during the day. Until reading Dubois' chapter on constipation, a nightly laxative had been absolutely necessary. After reading this chapter, she abandoned all drugs. She began her day one hour earlier, merely in order to follow exactly to the minute the system laid down, but otherwise there was no change. The result speaks for itself, and the cause of this brilliant result is not far to seek;—a wise hygienic system, recommended with absolute assurance, backed up by authoritative mention of many cures, and explained simply, clearly, suggestively; in short, efficient suggestion. This patient since her own cure, has cured two other similar but more severe cases, by means of this same excellent chapter.

It is hardly necessary to quote authorities to prove the importance of suggestion, for it becomes evident as we have seen, merely by intelligent observation of daily experience. However, a list of the names of the foremost psychologists of to-day would serve my purpose as authorities, for the presence of suggestibility in the waking state is accepted by all as one of the fundamental facts of psychology. For example, Bernheim in his "Suggestive Therapeutics" shows that suggestibility obtains not only in hypnosis but in the waking state as well.

There is overwhelmingly strong evidence of the therapeutic power of suggestion in its simplest form, without hypnosis, in Dubois' now well-known book, "Psychic Treatment of Nervous Disorders." That the author creates some unnecessary confusion by giving the name of "rational persuasion" to that which has been defined by the best authorities as suggestion, is of very little moment. His psychotherapy none the less depends absolutely on the laws of suggestion, not only in its method of application but also in its operation and results.

Lately Sidis, by a series of very careful scientific experiments, described in his really remarkable book "The Psychology of Suggestion," has proved beyond peradventure that "man is a suggestible animal, par excellence," and that "the subwaking self surpasses the waking self in sensitiveness normally as well as in hypnosis."

G. von Voss shows his conviction of the extent of normal suggestibility by saying: "Hypnosis is not a pathological condition; it can be produced in almost every normal human being."

Forel states in "Hypnotism and Psychotherapy": "I cannot emphasize sufficiently that suggestibility is an absolutely normal characteristic of the normal human brain." Illustrating the power of unconscious adverse suggestion the same author says: "I am fully aware that I once suggested a gastric ulcer to a patient in whom I suspected this condition, by having a serious countenance and by carefully palpating the region of the stomach, and ordering rest in bed and a milk diet. I suggested the pain by means of a pointed question, and the result of my want of knowledge of suggestion at this time was that the patient was confined to her bed for many months by a suggested illness, which was not really there."

Many other well-known names such as Vogt, Moll, James, and Münsterberg could be added to the list. Authority is not lacking, the facts are clear, and the clinical results evident. Indeed, there is to-day no more excuse for neglecting suggestion than there is for neglecting any other therapeutic agent of recognized activity. In fact, there is less reason for so doing, for unlike drugs and instruments, suggestion when neglected, will not lie quietly in an unused corner of the medicine cabinet, but follows the physician about willy nilly and exerts its power haphazard for good or evil through him on each one of his patients.

The importance of avoiding adverse suggestion is but the logical corollary of the foregoing. Adverse suggestion is manifestly as great a sin against efficiency as is the use of dull instruments or impure drugs.

To avoid the evils of adverse suggestion and to take advantage of all the good inherent in favorable suggestion is clearly the duty of every physician. To accomplish this with complete success, it is necessary that one should always keep vividly before one's mind the following facts:

1. The ultimate object of all medical work, whether clinical, experimental, chemical, or whatnot, is relief of suffering. 2. Suffering is a mental process and stands in relation to bodily ills not only as effect, but also as cause. 3. Every patient is suggestible and is, therefore, a highly individualized psychological as well as a physiological problem, and should be studied and treated as such.

Therefore, it is obviously as necessary that the physician should acquire a knowledge of psychology and of its application to medicine as it is that he should be familiar with physiology, pathology, or materia medica, for they are all intimately correlated component parts of the one great entity—the Healing Art.

THE RELATION OF PLEURISY TO PULMONARY TUBERCULOSIS.

By HENRY S. GOODALL, M.D.,
LAKE KUSHAQUA, NEW YORK.
MEDICAL SUPERINTENDENT, STONY WOLD SANATORIUM.

The relation of serofibrinous pleurisy to pulmonary tuberculosis has attracted the attention of medical men for many years, and that the relation was thought to be close and important long before the tubercle bacillus was discovered is shown by the following written by Niemeyer[1] in 1867 concerning the prognosis of pleurisy. He says, "When the malady is of a creeping, in-

sidious type, the prospect is much more grave than in the acute type, as even after complete absorption *tuberculosis frequently appears as a sequel.*" Many other writers of that and earlier days mention the same fact more or less positively. As a result of the discoveries made since then in the fields of bacteriology, hematology, cytodiagnosis, etc., it has become more and more apparent that there is between pleurisy and pulmonary tuberculosis an even closer relation than was dreamed of at that time.

This relation we will consider under two heads, namely, pleurisy as a complication of pulmonary tuberculosis, and pleurisy as a forerunner of tuberculosis, that is, as the initial manifestation of tuberculosis. The word initial is used here in a purely clinical sense, without intending in any way to decide whether such pleurisies are really primary or secondary, pathologically. They are considered as initial attacks of tuberculosis simply because no previous manifestation of tuberculosis can be traced and no evidence of it can be found at the time of the pleuritic seizure except the pleurisy itself.

The first class is very familiar to us all and we can pass over it somewhat briefly. A review of 450 cases treated at Stony Wold Sanatorium reveals the fact that 204 cases, or 45 per cent., suffered from pleurisy during their residence at the sanatorium. This includes all degrees of pleurisy from the slightest dry pleurisy to cases with very large effusions. The great majority of the cases, however, were cases of dry pleurisy. Former Surgeon General Banks[2] of the Marine Hospital Service found 279 cases of pleuritic adhesions in 371 complete necropsies of tuberculous patients, a little over 75 per cent. These adhesions varied from a mere thread to a massive adhesion which bound the entire pulmonary surface to the peripheral wall.

In spite of this frequency of pleurisy as a complication, the presence of preexisting tuberculosis gives us a clear and definite indication for treatment and leaves us in no doubt as to the necessity of prolonged care and watchfulness after the pleurisy itself has subsided. It should be noted that the tuberculous disease of the lungs is sometimes apparently aggravated by the complete withdrawal of a large effusion.

Pinquet[3] pointed out this tendency and explained it on the ground that the false membrane covering the pleural surfaces contained large numbers of bacili and that when these surfaces were rubbed together after the withdrawal of the effusion, the bacilli were set free and were carried into the lung tissue, while, on the other hand, the presence of fluid compressed the lung and kept it at rest, prevented the aggravation of pleural inflammation by friction of inflamed surfaces and kept the bacilli from doing greater harm by virtue of certain bacteriacidal elements contained in the effusion.

The recent work of Opie[4] shows that a complete withdrawal of a serous effusion may result in the formation of a purulent pleurisy by removing with the fluid certain antilytic substances which have held the zymotic activity of the cellular elements in abeyance. Complete removal of the fluid in Opie's experiments resulted in the rapid autolysis of certain cellular elements, more or less disintegration of the fibrin by the action of the cellular enzymes, increased inflammation of the pleural surfaces, increase of cellular elements in the fluid and the formation of pus.

His experiments also went to show that complete restoration of the pleural cavity to a normal condition was more rapid if the fluid was not totally removed. Opie says it is not believed that his experiments indicate that aspiration of serum from a serofibrinous case is dangerous and likely to convert it into a purulent case, but that they may "suggest that complete withdrawal of the serum is undesirable."

I feel that usually it is much safer in cases of pleurisy with serous effusion occurring in the presence of pulmonary tuberculosis to draw off only a small part of the fluid if respiration is embarrassed, or to leave it alone for a time if there is not enough fluid to cause dyspnea or other serious symptoms. If spontaneous absorption is too slow, the withdrawal of a small amount of fluid frequently leads to the speedy absorption of the rest.

Our present knowledge of toxins and antitoxins would lead us to believe that the serum of pleurisy contains anti-bodies which are taken up by the system if the serum is reabsorbed and which tend to produce a certain immunity against the tubercle bacillus and its products. This is borne out in experience by the fact that cases of pulmonary tuberculosis in which pleurisy with effusion occurs and in which the fluid is not withdrawn, or at most withdrawn only in part, frequently do remarkably well after the pleurisy subsides, and seem to show clinically, for a time at least, if not permanently, a much greater immunity to the tuberculous process than was shown before the pleurisy.

Before giving any statistics on the occurrence of pleurisy as a forerunner of tuberculosis it may be of interest to mention briefly the methods that may be used to determine the nature of a given case.

The history is of great importance, for if there has been continued exposure to tuberculosis, and still more if there has been a previous suspicion of tuberculous disease in the individual, the probability is great that the pleurisy is of a tuberculous nature, and even if there is some other cause present like the pneumococcus, still such cases should call for anti-tuberculous treatment after the pleuritis is gone. An insidious onset is the most suspicious point in symptomatology, though the occurrence of night sweats in a case with serous effusion would point strongly to tuberculosis.

The tubercle bacillus is, of course, conclusive evidence if found in the effusion, and it is probably best sought for by the method known as inoscopy. This consists briefly in drawing off the effusion with proper precautions to prevent its contamination, allowing it to clot, dissolving the clot by a mixture of hydrochloric acid and pepsin, centrifuging, and staining the sediment for tubercle bacilli. The bacilli are caught in the coagula and after these are dissolved the bacilli are collected into the small compass of the bottom of the centrifugal tube. Tubercle bacilli are very easily decolorized after passing through this process. Considerable care is needed to stain properly. At the Massachusetts General Hospital bacilli were found in 24 of 115 cases, or 20.8 per cent. Zebrowski[5] found tubercle bacilli in 65 per cent. of primary pleurisy and in 83 per cent. of pleurisy secondary to tuberculosis, by sedimentation of large amounts of fluid in which coagulation was prevented by sodium fluoride.

Animal inoculation is a very good way of testing the fluid for tubercle bacilli, but the strictest

antisepsis is imperative to prevent contamination with other organisms, particularly pus cocci which would kill the test animal before the tubercle bacilli had time to cause any characteristic changes. A rather large quantity of serum must also be used or negative results are probable. Several times as many positive results will be obtained by injecting 15 or 20 c.c. than by using 1 or 2 c.c. for the inoculation. Le Damany[6] was able to get 85 per cent. of positive results by inoculation, using from 10 to 50 c.c. and even as high as 300 c.c. of serum.

It has been found in some instances that no bacilli could be found microscopically and yet animal inoculation demonstrated the fluid to be tubercular. Conversely, bacilli may be found microscopically in fairly good numbers and the inoculation prove negative. In the latter case the bacilli are probably dead or at least avirulent.

Another test of the nature of a pleuritis consists in using some of the serum as we use tuberculin. If injected into an animal known to have tuberculosis, a tuberculin reaction should be produced if the serum is from a tuberculous patient.

These methods, inoscopy, inoculation, and the tuberculin reaction are all practically out of the question except in the laboratory. They are all more or less difficult in point of technique, and unless one has used them extensively he cannot hope for very great results. The fact that different observers, who have become expert, have obtained positive results in such large percentages of cases of serofibrinous pleurisies is, however, of very great importance.

The method of cytodiagnosis is a useful one, but, like the others, requires much practice to enable one to get reliable results. It is possible to use it outside of a laboratory, and in this respect it is more generally usable than the preceding methods. Cytodiagnosis is performed as follows: The fluid should be drawn with the usual antiseptic precautions, and when clotted should be stirred with a glass rod and shaken until the clots are thoroughly contracted and the cells are squeezed out of the meshes of the clot. Better still, clotting may be prevented by mixing the serum with half its volume of salt solution. The fluid is then centrifuged for five minutes and the supernatant fluid decanted. The sediment is mixed with the few drops of fluid that remain in the tubes and cover glass smears made from it. These are stained by one of the methods of differential staining and a differential count of the leucocytes is made. Musgrave[7] recommends Wright's blood stain three parts, pure methyl alcohol one part. Differential staining is needed because the nucleus of a degenerated polynuclear cell may swell up and assume the same shape as that of a mononuclear cell, and it is only by the different manner in which the two nuclei stain that they may be distinguished. A large excess of lymphocytes indicates a tuberculous origin, while an excess of polynuclear cells would point to an acute infectious cause.

In pleurisies secondary to pulmonary tuberculosis, the lymphocytes are not found but are replaced by necrotic cells and detritus. This, however, does not matter much because in these cases we have other evidence of the presence of tuberculosis. The specific gravity must be 1015 or more and the percentage of albumin 2 or more to distinguish from a mechanical transudate, as lymphocytes may predominate in a transudate of long standing. They may also predominate when an acute infectious case is subsiding or when the infection is very slight. Working on these lines Musgrave was able to recognize 64 per cent. of 72 cases as tuberculous, and these findings were verified by other means in most of the cases. Carter[8] also succeeded in identifying a large percentage of cases by this method.

Differential blood counts cannot be considered of positive diagnostic value, but a low leucocyte count suggests tuberculous pleurisy, while a high leucocytosis suggests either empyema or pneumonia or a pleurisy due to pneumococci. Micheleau[9] asserts that hyperchloruria indicates that the pleurisy is tuberculous.

Our records at Stony Wold Sanatorium show that 193 cases, or 43 per cent. out of 450 cases reviewed had pleurisy preceding their admission and 10 per cent. gave a history of pleurisy preceding other symptoms of phthisis. Dr. K. Thue[10] records 30 cases of serous pleuritis, 17 of whom showed later that they were tuberculous. Dr. George B. Sears[11] collected 439 cases of pleurisy treated at the Boston City Hospital. These were cases where there had been no cough, hemoptyses, hip disease, or other reason for thinking that they were secondary, that is, to all appearances they were cases of true idiopathic pleurisy, the "pleurisy a frigore" of former writers. It was found that 86 or 20 per cent. had died within 17 years and 23 others probably shared the same fate, although the records of these cases were not perfectly clear. The causes of death are as follows:

	Positive Class.	*Doubtful Class.*
Phthisis	45	13
Pleurisy	5	1
Empyema	1	0
Bronchitis	3	0
Edema lungs	1	0
Pneumonia	6	4
Meningitis	3	2
Other nonpulmonary causes	22	3
	86	23

If we consider only those cases in the first list who died from phthisis we find that 52.3 per cent. of the cases dead within 17 years died of pulmonary tuberculosis, and in addition to these we have 5 who died of pleurisy, 1 of empyema, 3 of bronchitis, 1 of edema of the lungs, and 3 of meningitis, in all of whom the probability is strong that the tubercle bacillus was the direct cause of death. If we compare the number of deaths with the entire number of cases we find that 10 per cent. died of pulmonary tuberculosis, or 13 per cent., if we include the cases of pleurisy, etc., which were probably of tuberculous nature. If we also include, as seems to me fair, the 16 cases dead of tuberculous disease among the 23 whose histories were open to suspicion but which were in all probability correct, we have 17 per cent. of the 439 cases of idiopathic pleurisy that died of tubercular disease within 17 years, or if we view it from another standpoint we see that 69 per cent. of those who died within 17 years died of tuberculosis.

Dr. R. C. Cabot[12] gives rather more favorable figures. Among the 152 cases of apparently primary pleurisy with serous effusion that he was able to trace, 15 per cent. subsequently developed demonstrable tuberculosis and 55 per cent. of the total deaths were due to this disease. Dr. Percy Musgrave classified 72 cases of pleurisy with effusion treated at the Massachusetts General Hospital according to the cytological formula of Widal and Ravaut and found 45 cases, or 65 per

cent., to be of tuberculous nature. Dr. A. G. Barrs[13] reports 57 cases of pleurisy with effusion treated at the Leeds Infirmary, 21 of which died of tuberculosis, and Fiedler[14] reports 92 cases, 28 of which died of tuberculosis within two years, 48 others had more or less definite signs of pulmonary tuberculosis, and only 21 of the 92 cases remained healthy—82.6 per cent. subsequently suffered with pulmonary tuberculosis.

It may be of interest to notice the length of life among those dying of tuberculosis following pleurisy. In the series reported by Sears, counting only the first or positive series, 40 per cent. of the deaths from tuberculosis occurred in the first two years, 31 per cent. between the second and fifth years, that is, 71 per cent. in the first period of five years, 12 per cent. died in the second, and 16 per cent. in the third five years, and only one case lived to the sixteenth year.

That family history is important as an element in diagnosis and also in prognosis appears from the following figures: In Cabot's cases 67 per cent. of those that developed tuberculosis gave a history of predisposition or rather of exposure from occurrence of tuberculosis at an earlier time in the members of the patient's family or in the patient himself, while only 25 per cent. of those who remained well for five years had been so exposed. In Grober's[15] series 45 per cent. of the cases that developed tuberculosis after idiopathic pleurisy had been exposed to infection through the previous occurrence of that disease in other members of their families.

In reviewing the foregoing we see that a very large percentage of cases of apparently primary serofibrinous pleurisy may be demonstrated to be of tuberculous nature by laboratory methods, provided the investigator is sufficiently proficient with the method employed. We find, moreover, that in various series of cases that have been followed for some years after the serofibrinous pleurisy, a large number show tuberculosis, the figures varying from 15 per cent. in Cabot's series to 82.6 per cent. in the series of Fiedler.

While it must not be forgotten that pleurisy with effusion may accompany lobar pneumonia or may be caused by the pneumococcus without pulmonary involvement, and that it may also result from streptococci, staphylococci, and other microorganisms as well as from cancerous disease; and while we must also remember that serous fluid in the pleural cavity may be merely a transudate due to renal or cardiac disease, we must nevertheless be convinced that all these causes together are responsible for only a minority of the cases of so-called idiopathic serofibrinous pleurisy, the majority being cases of tuberculosis of the pleura and to be treated accordingly.

Those of us who have opportunity to gain special experience in tubercular work so frequently see pulmonary tuberculosis developing within a year or two after an attack of serofibrinous pleurisy, recovery from which had apparently been good, that we are ready to accept the conclusion of the figures cited above, namely that the great majority of initial serofibrinous pleurisies are of a tubercular nature.

From this it follows, and I wish to urge this conclusion upon my readers as strongly as possible, that when called upon to treat a case of apparently primary pleurisy with serous effusion, it is the physician's duty to bring to bear upon it as many methods of determining its nature as possible, and that only when there is positive evidence of a cause other than the tubercle bacillus should he discharge the case.

In all serofibrinous pleurisies the absence of a demonstrable positive non-tuberculous cause should be accepted as a presumptive evidence that the case is really one of tubercular pleurisy, and the case should be watched and handled as a case of incipient tuberculosis for a period of not less than two years. I do not wish to be understood that such a case must go to a health resort for such a length of time or that he must necessarily give up work, but I do mean that he should be kept under close observation, that his chest (the whole of it, and that devoid of all clothing) should be examined at intervals of at most two or three months if he appears well, oftener if there is any evidence of impaired health, and that he should be told to regulate his mode of life, his work, his meals, his rest, and his fresh air in accordance with the general rules applicable to tuberculosis in general, and to the particular conditions that may be found at the examination from time to time. If the patient's means will permit I believe that a sojourn of a few months at a health resort under the care of some reliable specialist is well worth while, especially if symptoms of other tuberculous trouble develop.

I wish to call attention particularly to the fact that, although it is not the rule, signs of pulmonary tuberculosis not infrequently are found first at the upper part of the lung opposite to the side on which the pleurisy occurred. For this reason the entire chest must be investigated.

By following this course, while we may perchance exercise control in an occasional case where control is not needed, we will certainly pluck many and many a case from the grasp of the Great Destroyer and prolong many useful lives that would otherwise follow the downward course so common in untreated or tardily treated cases of tuberculosis. This is the more true because, as shown by Cabot's cases, the type of tuberculosis following pleurisy with effusion is usually not very violent, and we may therefore expect very satisfactory results from suitable prolonged supervision and treatment.

WM. WOOD & CO., 51 FIFTH AVENUE.

New York, June 27, 1908.

PROPHYLACTIC INJECTIONS OF DEAD STREPTOCOCCI IN SCARLET FEVER.

OF all European countries Russia shows the greatest morbidity as well as mortality so far as scarlet fever is concerned, and it is perhaps this fact that has led the Russian physicians to special activity in devising methods to fight the frightful epidemics that often take place in the villages. The results of their efforts have remained for the most part unknown to the American profession being published chiefly in the Russian journals, yet they have been striking enough in recent years to deserve attention of the entire medical profession. Some years ago Gabritchevsky began to use injections of dead streptococci in the treatment and prevention of the disease, sharing the view of those who saw in that organism the specific cause of the disease. This view was strengthened in his mind by the similarity of the symptoms of the disease in human beings with those of an infectious adenitis of horses caused by the streptococcus.

Accordingly, Gabritchevsky isolated a streptococcus from the heart blood of children dying of scarlatina and then grew it on the usual artificial media. The first experiments with the dead cultures were made by him on himself and on his children, and after these proved to him the harmlessness of the procedure he supplied the vaccines in large quantities to the Russian profession. From that time till April, 1908, 37,000 persons have been treated in accordance with his ideas, over 50,000 injections having been made, for it was soon seen that repeated treatment was much better than a single injection of the dead bacilli. The injection is usually followed by redness, a slight rash, and some swelling at the site of the puncture; the regional lymph nodes often become swollen and painful; the temperature is slightly elevated; the child becomes irritable, weak, and loses its appetite; but all these symptoms disappear in a few days. The preventive value of the injections may be judged by some instances quoted in an article by Danilow in *Russkii Vrach*, of May 17, 1908. In two villages where scarlet fever appeared all the children were immediately vaccinated; in the first village no more cases of the disease occurred among children, but two unvaccinated adults were infected; in the second village the vaccinated children remained healthy, but a boy who came from another place on a visit was taken with the fever. Dreyling tells of vaccinating six children of a peasant's family, the seventh, a little girl, having hidden herself to escape the injection. Four days later she developed scarlet fever. Another unvaccinated child was admitted to the hospital together with an elder sister who was to act as nurse; she had been vaccinated and remained free of the disease though constantly in the scarlatina ward. In another family the elder children were vaccinated, but the parents refused to permit the treatment for themselves and for two babies; in a few days three of the unvaccinated adults came down with the disease; then the youngest children were vaccinated and remained healthy. The general effect of the vaccinations are best seen in the figures of morbidity given by Danilow. Only 1.1 per cent. of all the vaccinated persons were taken sick with scarlet fever; of those vaccinated once 1.21 per cent. were later attacked by the disease, 0.73 per cent. of those vaccinated twice, and 1.09 per cent. of those vaccinated three times being affected. The total mortality from scarlet fever of the vaccinated persons was but 0.123 per cent.; the mortality of those who became sick in spite of the prophylactic injections was 11.1 per cent. During the epidemics many cases of course must have been injected while in the incubation period of the disease and cannot therefore be used to calculate the prophylactic effect of the treatment.

The above results obtained in the last two years and a half deserve attention from the physicians of other lands as well as of Russia. Since the ravages of diphtheria have been successfully diminished by the antitoxin treatment, scarlet fever has remained the one great disease of childhood, dangerous in itself and bringing with it a host of complications that may kill the child soon after the original disease or make him a weakling or an invalid throughout life. Gabritchevsky's method should certainly be tried wherever possible so that its value in the treatment and prophylaxis of scarlet fever may soon be determined.

THE TOLERANCE BY THE TISSUES OF SURGICAL MANIPULATION.

IF one is to judge by the impunity with which surgeons attack the various structures of the body, he can only conclude that the tolerance of the latter to such manipulations is almost unlimited. The literature contains accounts of a large number of cases in which repeated operation in the same part of the body has been necessary for the relief of morbid states. Fortunately, nature has been prodigal in providing functionating structure in excess of the actual or ordinary needs of the organism, so that a certain amount of loss can be borne without disturbing the metabolic equilibrium of the body. Moreover, many of the tissues possess the power of regeneration to a compensatory degree; and, besides, the functions of organs destroyed, in whole or in part, can be, in some measure vicariously assumed by other organs or tissues. The behavior of the kidneys in the presence of conditions such as those here under discussion is dealt with in an interesting manner by Dr. W. Wayne Babcock, who reports in the *Annals of Surgery*, No. 4, 1908, a small group of notable cases in which multiple and successive operations on the kidneys were necessary and carried out. In one of these bilateral nephro-

lithotomy was performed one year after double nephrotomy for bilateral calculous disease; one year later one kidney was drained; a year later later still nephrectomy was performed; another year later the remaining kidney was opened and a number of recurrent calculi removed. In another case, two years after nephrolithotomy on one side, the same operation was performed on the opposite side; one year later bilateral nephrostomy was performed by two operators working simultaneously; and in the following year nephrectomy was performed. In other cases still appendectomy, nephrolithotomy, and secondary nephrotomy; appendectomy, nephrolithotomy, and nephrectomy; nephrolithotomy, nephrostomy, and secondary nephrectomy and ureterectomy; litholapaxy and secondary nephrolithotomy were performed consecutively.

Among the conditions that predispose to the reformation of renal calculi after nephrolithotomy are infection, failure to remove all stones or fragments or other foreign bodies, and the persistence of the factors responsible for the presence of the original calculus. In the experience of Dr. Babcock, bilateral or consecutive operations upon the kidneys are well borne in the absence of infection. Nephrolithotomy, he finds, is frequently followed by reformation of stone in the kidney. Nephrostomy may not only fail to cure, arrest, or prevent pyelonephrosis or relapsing nephrolithiasis, but it may even favor the development of one or other of these conditions. In operating for simple calculous disease of the kidneys, Dr. Babcock advises the avoidance or only temporary use of postoperative drainage, and then with the most rigid aseptic precautions.

REPARATIVE PROCESSES IN ANEMIA AND LEUKEMIA.

The practising physician who has to do with differentiated tissues and organs but seldom observes an example of a reversion on the part of these structures to an earlier, less specialized type so far as their function is concerned. The pathologist, on the other hand, in the innumerable phenomena and results of disease that he observes by the finer methods of the laboratory, frequently meets with instances of such reassumption of type and function on the part of organs or their elements when affected by an extraneous or irregular new factor. Thus Meyer has shown (*Münchener medizinische Wochenschrift*, June 2, 1908) that the liver, the spleen, and frequently the lymph nodes assume a fetal type in grave or pernicious anemias as far as their cellular character is concerned. Erythroblastic cells and newly formed leucocytes appear in them, while the blood-making organ of the adult, the bone marrow, shows likewise a picture of greatly increased activity.

Meyer, together with Heinecke, has interpreted these phenomena as reparative in nature in opposition to another conception of the findings which seeks to interpret them as the primary result of some unknown harmful agent. Von Domarus has greatly strengthened the standpoint maintained by Meyer by producing experimental anemias in animals and showing that the changes in the blood-making organs of intrauterine as well as of extrauterine life were similar in these animals to those observed in patients with pernicious anemia. The view of anemia defended by these authors answers very well to the modern conception of the phenomena of disease as processes of adaptation or compensation under new surroundings. To accept it, however, means to differ completely from some recently practised measures in the treatment of anemias and leukemias. The removal of the spleen in lymphatic leukemia would of course be a highly illogical procedure. The exposure of the bone marrow to the effect of the *x*-rays, too, would simply mean the interference with local reparative processes without sufficient reason to believe that their continuation was harmful to the rest of the organism.

Fracture of the Radius with Injury of the Median Nerve.

Very little has been written concerning median nerve injuries complicating fractures of the lower end of the radius. The fact that tendons and the pronator quadratus separate bone and nerve probably accounts for the rarity of injuries to the latter; furthermore, dislocation of the fragments in fractures of the lower end of the radius is rare and the callus is usually small. But the fact that injury to the nerve is rare makes a knowledge of its possibility none the less important. In the April number of the *Deutsche Zeitschrift für Chirurgie* Blecher has collected all the cases of injury of the median nerve following fractures of the lower end of the radius heretofore reported and adds a case of his own. He distinguishes between primary and secondary nerve injuries, the former caused by pressure of a fragment at the time of fracture, the latter by the callus. The primary variety is less frequent and is usually not diagnosed until at the time of first dressing, or three or four days after the injury, when the patient complains of a feeling of numbness, and complete motor and sensory paralysis is found in the region of the median nerve. Blecher recommends early massage, bathing, and faradization. Recovery occurs in the majority of the cases in from one and a half to two months; if by that time there is no improvement he advises resection and secondary suture of the nerve. When the injury is secondary, symptoms do not appear until from one to two and a half months after the injury and are due to the nerve being stretched or subjected to friction by the callus. When due to the latter the symptoms usually disappear when the hand is put at rest. The symptoms begin with pains in the fingers, paresthesias, and only slight motor and sensory disturbances. As treatment he advises immediate removal of the callus, this operation always being followed by cure of the condition. Though injury of the median is rare in cases of fracture of the lower end of the radius, the early diagnosis is of great importance as the prognosis is best when treatment is begun early. For this reason it is advisable to test the functions of the median nerve when the fracture is first put up. The secondary injuries can be prevented only by good apposition of the fragments, and not always even then.

Antitryptic Power of Human Blood Serum.

The claim of John Beard of Edinburgh that the pancreatic ferments, trypsin and amylopsin, are

curative in cancer, with the lively discussion which followed his announcements, gave an impetus to the study of the relation of enzymes in general to the diseased organisms. Brieger and Trebing have recently investigated the effect of human blood serum upon the digestive power of trypsin (*Berliner klinische Wochenschrift,* June 1, 1908), mixing the two in various proportions and using plates of Löffler's medium for testing the effect produced. Normal blood serum was able to prevent tryptic action in the strength of one part to three or four of the ferment. Thirty-five sera of patients suffering from carcinoma showed great increase in the antitryptic power when compared with the normal figures, proving capable of preventing the action of the ferment in dilutions of one part serum to from six to ten parts of the enzyme. The sera of patients with suspected carcinomatous disease showed a similar increase in the antitryptic property, while the existence of tumors of other types seemed to leave the serum in its normal condition in this respect. Successful operation in cases of cancer seemed to have the significant effect of again reducing the antitryptic power of the serum to its normal limits, but the observations were too few in number to justify any final conclusions. The sera in other diseases gave varying results though no such uniform increase in the antitryptic power could be observed except in a few cases of grave anemia. How far the reactions studied may be utilized in the differential diagnosis of carcinoma can only be decided after similar observations on more abundant material have been made.

Blood Pressure and the Streptococcus Toxins.

It is well known that one of the most important manifestations of toxemia in infectious diseases consists in the progressive fall of the general blood pressure. Huchard indeed takes this fact as the basis for a classification of diseases, calling all infectious conditions hypotensive, all other hypertensive diseases. Experimental work, however, has weakened such division, it being shown that some bacteria, *e.g.* pyocyaneus and staphylococcus, cause increase and not a fall in the blood pressure. Kurt Tautz (*Centralblatt für Bakteriologie,* Band XLVI, Heft 6) examined *Streptococcus pyogenes* with reference to this point. The primary effect of intravenous injections of streptococci cultures was an immediate rise of blood pressure which was followed by a gradual and step-like fall. After a half hour the blood pressure returned to its original height, reaching it not gradually this time but in several quick changes which were accompanied by disturbed respiration and convulsive movements of the animal. Tautz concludes that no latent period is present in the effect of the toxins upon blood pressure, in contradistinction to the existence of such a period when large quantities of living bacilli are introduced into the blood of animals. The results, of course, apply strictly to the species of bacilli used in the experiments, namely the pyogenic streptococci, and further work with other bacteria may be awaited with interest.

Cesarean Sections Under Spinal Anesthesia.

General ether or chloroform anesthesia for cesarean section possesses the disadvantage of often seriously affecting the unborn child and interfering with the regular initiation of respiration, in addition to being dangerous in the presence of severe kidney or lung lesions in the mother. To obviate these dangers Polano has tried lumbar anesthesia for this operation with perfect results in the four cases so far observed (*Münchener medizinische Wochenschrift,* June 2, 1908). The operative interference proved to be completely painless, the uterus contracted firmly after the removal of the child, and the postoperative course was very satisfactory. In every instance the child began breathing and crying immediately after the delivery, thus showing that the interruption of the placental circulation and the mild external stimuli to the skin are sufficient to initiate respiration in the newborn, the more vigorous stimuli of pressure upon the head, of partial asphyxia, etc., present in the normal deliveries not being necessary to start this function. The results obtained by the author lead him to recommend to other gynecologists the trial of spinal anesthesia in cesarean section.

News of the Week.

Medical and Hospital Corps of the United States Navy.—Recent legislation has materially improved the status of the members of these two corps, and new circulars of information are being issued by the Surgeon-General of the Navy. Fifty-four vacancies exist in the Medical Corps, and a large number of men are needed in the Hospital Corps, including druggists for hospital stewards.

Naval Medical Corps.—A candidate for appointment must be a citizen of the United States, twenty-one to thirty years of age, and must present testimonials as to character and professional fitness. Examinations are conducted under three heads: physical, professional, and collateral. The physical examination is thorough and includes tests of vision and color perception. The professional examination covers medical subjects, and the collateral general high school studies. Examinations are held by the Naval Examining Boards at the United States Naval Medical School, Washington, and at the United States Naval Hospital, Mare Island, Cal. The officers of the Medical Corps of the Navy and their respective base pays are as follows: Medical Director, $4,000; Medical Inspector, $3,500; Surgeon, $3,000; Passed Assistant Surgeon, $2,400; Assistant Surgeon, $2,000. Calculated on this annual base pay the salary of officers is increased ten per cent. for every five years of service, though the pay of Medical Director is limited to $5,000, that of Medical Inspector to $4,500, and that of Surgeon to $4,000. At the expiration of three years of service, assistant surgeons are examined for promotion, and if successful become Passed Assistant Surgeons. Provision is also made for the appointment of Acting Assistant Surgeons, who receive an annual pay of $1,400 for shore duty and $1,700 for duty on board ship. After appointment, each candidate will receive a course of instruction at the Naval Medical School, on the completion of which an examination will be given for admission to the regular service as Assistant Surgeon. Physicians desirous of becoming candidates should apply for information to the President of the Naval Examining Board at either of the examining stations mentioned above.

Naval Hospital Corps.—This corps comprises four classes: (1) Hospital apprentices, who must be from 18 to 25 years of age, and who receive a pay of $22 per month; (2) Hospital apprentices, first class, who must be from 21 to 28 years old, and are paid $33; (3) Hospital stewards, from 21

to 30 years, with a pay of $66 to $77 per month; (4) Pharmacists, whose salaries range from $1,200 to $2,250 per year. All applicants must be citizens of the United States and must enlist for a term of four years' service in any part of the world, either ashore or afloat. Examinations are held at all navy yards and navy recruiting stations, whenever an applicant presents a permit, which can be obtained by application to the Surgeon-General of the Navy at Washington. Candidates for admission to the first class are examined in general subjects, and will find a knowledge of nursing of advantage. For the second class the examination covers in addition, subjects in nursing, such as preparation of patients for operations, preparation of food, beds, charts, etc., and other knowledge necessary for nurses in charge of wards, assisting at operations, etc. Members of these classes are eligible after one year for admission to the higher grade after examination. For hospital stewards examinations are held in general education, and in materia medica, pharmacology, chemistry, toxicology, compounding prescriptions, and minor surgery. Vacancies in the grade of pharmacists are filled only from the class of hospital stewards in order of length of service and upon record and fitness as determined by examination.

Campaign Against Tuberculosis.—The subcommittee on education of the Albany Committee on the Prevention of Tuberculosis has obtained permission from a number of the managers of factories in that city to arrange for a series of short talks on tuberculosis to their employees during the noon hour or following the closing hour. Great interest in the matter has been shown and it has been arranged to present a series of simple lessons treating of the nature of the disease, and means of communication, prevention, and cure.

Ball Game in Aid of Hospital.—Laying aside for the moment their professional dignity the lawyers and physicians of Tarrytown, N. Y., joined in a baseball game for the amusement of the townspeople and for the purpose of raising the $3,000 necessary to obtain a $25,000 gift for the Tarrytown Hospital building fund.

Addition to Roosevelt Hospital.—Plans have been filed for a two-story pavilion to be built on the grounds of the Roosevelt Hospital and to be used for the pathological work of the hospital. The building is to be the gift of Dr. James W. McLane, and will fill a need which has long been greatly felt.

Kansas University Medical School.—Commencement exercises were held on June 8, and the degree of M.D. was conferred on eighteen graduates. Professor Findley of the University of Nebraska spoke on "The Heroes of Medicine."

Mercantile Inspection Bill.—Governor Hughes on June 16 signed the bill transferring the inspection of all mercantile establishments in cities of the first class from the local boards of health to the State Labor Department. A new bureau is to be established under the State Commissioner of Labor.

Ambulance in Collision.—While transferring a patient from St. Luke's Hospital to Bellevue on June 15, the St. Luke's ambulance was struck by a street car, and the surgeon, Dr. Johnson, was thrown to the street and seriously injured. The patient was not hurt.

Cornell University Faculty.—The trustees of Cornell University have announced the appointment of Dr. Sutherland Simpson of the University of Edinburgh as professor of physiology, and of Dr. Andrew Hunter of Leeds University, England, to be assistant professor of biochemistry, at Cornell. Prof. Simon H. Gage of the department of histology and embryology, who retires to take up research work, has been made a professor emeritus.

Pasteurized Milk Stations.—In addition to the six stations maintained throughout the year by Mr. Nathan Straus for the distribution of pasteurized milk in New York, eleven summer stations were opened on June 17. These are situated on the recreation piers and in the parks of the city where the service will be most useful. The report for the past eight months shows a steady increase in the demand for the milk.

The Coming Epidemic of Tetanus.—The Chicago Department of Health devotes considerable space in its weekly bulletin to the 4th of July celebration and the annual epidemic of tetanus. It gives the cause of the disease, and the proper treatment of 4th of July wounds. It likewise announces that it will supply tetanus antitoxin for the treatment of all suspicious injuries for the two weeks preceding and succeeding the 4th of July.

Dr. Adolph Meyer of New York City has been elected by the trustees of the Johns Hopkins Hospital and University to the Directorship of the recently founded Henry Phipps Psychiatric Clinic and to the Professorship of Psychiatry.

City League to Guard Public Health.—The Chicago Local Advisory Committee of the American Health League was transformed recently into a permanent society prepared to give aggressive attention to local health problems. Professor C. R. Henderson of the University of Chicago was elected President, and Professor J. P. Goode of the University of Chicago, Secretary and Treasurer. The Executive Committee is composed of Health Commissioner Dr. W. A. Evans, Dr. George W. Webster, President of the State Board of Health, Adolph Nathan, Miss Jane Addams, and C. Loesch. The work of the League will consist in investigating health problems in Chicago and attempting to get correctional and preventive legislation through the city council and State legislature.

Smallpox on Army Transport.—The transport *Sherman* on its arrival at Astoria, Wash., on June 14, reported one case and one death from smallpox. The *Sherman* left Manila on May 15, with 521 enlisted men, and about 150 additional passengers. A strict quarantine will be enforced. It is reported that almost the entire army is protected by vaccination.

Rabies in Washington.—Alarmed by the number of cases of rabies occurring in the District of Columbia, President Roosevelt has ordered the institution of precautionary measures and has issued an order reviving an old muzzling regulation, under which all dogs must be muzzled during the next six months.

The Massachusetts Medical Society held its annual meeting in Boston during the second week of June. The following officers were elected for the ensuing year: *President*, Dr. S. Presbrey, Taunton; *Vice-President*, Dr. D. E. Keefe, Springfield; *Secretary*, Dr. F. W. Goss, Roxbury; *Treasurer*, G. M. Buckingham, Boston; *Librarian*, Dr. D. H. Brigham.

The Maine Homeopathic Medical Society held its forty-second annual meeting on June 9, in Portland. Officers were elected as follows: *President*, Dr. John T. Palmer, Portland; *Vice-Presidents*,

Drs. George H. Rand, Livermore Falls, and William H. Kennison, Madison; *Recording Secretary,* Dr. L. A. Brown, Portland; *Corresponding Secretary,* Dr. Carrie E. Newton, Brewer; *Treasurer,* Dr. William S. Thompson, Augusta.

American Orthopedic Association.—At the twenty-second annual meeting of this society, held in Chicago on June 4 to 6, the following officers were elected: *President,* Dr. Ansel G. Cook, Hartford, Conn.; *Vice-Presidents,* Drs. Albert H. Freiberg, Cincinnati, and Augustus Thorndike, Boston; *Secretary,* Dr. Robert B. Osgood, Boston; *Treasurer,* Dr. Gwillym C. Davis, Philadelphia; *Executive Committee,* Drs. John Ridlon, Chicago, Robert W. Lovett, Boston, and Reginal H. Sayre, New York; *Delegate to the Congress of American Physicians and Surgeons,* Dr. Virgil P. Gibney, New York; *Alternate,* Dr. H. A. Wilson, Philadelphia.

The Canadian Medical Association at its annual meeting in the second week of June, elected the following officers: *President,* Dr. R. J. Blanchard, Winnipeg; *Secretary,* Dr. Elliott, Ottawa; *Treasurer,* Dr. H. P. Small, Ottawa.

Canadian Valley (Okla.) Medical Association.—The physicians of Oklahoma County, Okla., have organized a medical society under this name and have elected the following officers: *President,* Dr. I. J. Wood, Jones City; *Secretary,* Dr. Townsend, Choctaw.

Obituary Notes.—Dr. Enoch Vine Stoddard of Rochester, N. Y., died at his home on June 6, at the age of 67 years. Dr. Stoddard was born in New London, Conn., July 10, 1840, and received his degree in arts from Trinity College, Hartford, in 1860. He began the study of medicine at Yale, but was graduated from the Albany Medical College in 1863, and served as a surgeon in the 65th New York Volunteer Infantry during the next two years. From 1873 to 1890 he was professor of materia medica and therapeutics in the medical department of the University of Buffalo, and since then has been professor emeritus. For many years Dr. Stoddard was president of the New York State Board of Charities and rendered most efficient service in that capacity.

Dr. T. W. McCarthy of Rockville, Mass., died on June 10, after an attack of pneumonia, at the age of 24 years. He was a graduate of the Baltimore Medical College in the class of 1906.

Dr. Nathaniel Borden Aldrich of Fall River, Mass., died after an operation for appendicitis on June 6, at the age of 42 years. Dr. Aldrich was graduated from Harvard Medical College in 1889, and since graduation had practised in Fall River, where he had a large surgical practice.

Dr. William M. Mercer of Pittsfield, Mass., died at his home on June 8, of heart disease, at the age of 65 years. Dr. Mercer was a graduate of Harvard Medical College in the class of 1866, and was a member of the Berkshire District Medical Society and the American Medical Association. For thirty-three years he had served on the Pittsfield school committee, and had held other city offices.

Dr. Harry E. Ballard of Bridgeport, Conn., died on June 11, aged 35 years. Dr. Ballard was graduated from the medical department of the University of Vermont in 1893.

Dr. Samuel Kitchen of Saginaw, Mich., died suddenly on June 9, aged 75 years. He was a graduate of the University of Michigan in the class of 1863, a veteran of the Civil War, and a prominent practitioner and citizen.

LETTERS TO A NEUROLOGIST.

To which are appended brief replies purporting to set forth concisely the nature of the ailments therein described with remarks on their appropriate treatment.

VII. From a Mother Whose Daughter Is Depressed.

Yonkers, N. Y., Feb. 15, 1907.

Dear Doctor:

Some years ago, I took my eldest daughter to the ——— Clinic to see you. You explained the nature of her illness, and told me that she would regain her health in about six months. She got well and has remained well since. I wish now to consult you about my youngest daughter. She is afflicted somewhat as ——— was ten years ago. This girl is twenty-seven years old and, like her sister, a stenographer. She has been a conscientious, hard-working, good girl, faithful to her employers, by whom she has been very much appreciated, and devoted to her parents, whom she has supported. She was of a lively disposition, rather fond of company, and not much given to moods. She scarcely ever insisted upon having her own way when it was in serious opposition to that of any other member of the family. Until toward the end of last summer she was apparently in her usual health. Then she began to develop the symptoms which are now so continuous and overwhelming. At that time none of us had any suspicion that they indicated the beginning of a trouble such as her sister had, but now there is little doubt. I fear, that it is something of the same nature. Although her condition does not seem so serious as did her sister's, I can see that it is growing worse, and I have been begging her to go to see you, hoping that you will be able to tell her what to do to get well. When she went away for a holiday last summer, she was tired, pale, and somewhat depressed. She was gone three weeks, and on her return she complained that the vacation had done her no good and that she could not go back to work. At times in her conversation to me she hinted that she was a failure, but I did not appreciate then what she meant.

She returned to her work and so far as I know she has done it to the satisfaction of her employers. She says, however, that she does it badly. She takes dictation from a member of the firm who is not thoroughly competent in English. Formerly she could interpret his meaning so well that, when the finished letter was handed to him the diction flattered him. Now she says that not only is it impossible to do this, but she makes many mistakes herself, and it takes her twice as long to do her work as it did before. She attempts to explain this incompetency by saying that she is being punished because she looked upon business merely as a makeshift until she got married, not realizing that it should have been made a life work. She is convinced that, if she had gone to it seriously, confidence would not have deserted her and she would not now be undeserving. She has the idea also that she is a social failure, that no one cares for her, that she is not essential to anyone, that her personality is not agreeable to anyone, and that even the other employees in the office are down on her. She remarks that they go out in pairs, that one awaits the other at the elevated station to go home together, that a number plan to spend Saturday afternoon or Sunday together, but no one asks her, or awaits her, or solicits her company or cooperation. In fact she says that

they do not like her, that they avoid her, that they talk depreciatingly about her, and she is sure that they know she is not up to her work.

When she comes home in the evening she throws herself down on the lounge and often has to be coaxed to take her dinner. She will not participate in any way in the little occurrences, and gossip of family life, nor are we able to persuade her to go out to meet people. Sometimes she will go for a walk with her sister, but she will not go to the theater or to church or to any social gathering; everyone must know she is a failure, she says. Alone with her sister or with myself she will talk unendingly of her lost confidence in her social ability, and of her failure in business. Her sister, who sleeps with her, says she awakens very early, and several times she has told her that the thought of doing away with herself has come into her head. She gets up at six o'clock every morning, but lately it takes her so long to dress that she is scarcely ever ready on time, which is so unlike her, as she used to be quick and alert. Moreover, she is losing flesh, and she shows in her appearance and in her actions that she is not well. She talks to me constantly about the uselessness of it, meaning the struggle to go on now that she is a social and business failure. It is absurd to keep going to business, she says, because every day she is getting more incapable, and it is only a matter of a short time when they will ask her to give it up, so it is preferable to leave now. It is such an effort for her to do the work which formerly she did easily, and it takes her so much longer to do it that it exhausts her. Even the thought of it overwhelms her. She says her thoughts are very slow and sometimes they will not come at all. Once or twice recently she has told me that everyone would be much better off if she were dead.

About two years ago she was keeping company with a young man and we believed she would marry him. But last spring when she began to be run down she gave him up because he was uncongenial. At first I thought her depression might have had to do with that, but it seems to have made no impression upon her and she never mentions him. In fact one of the things that is most mysterious to me about this change that has come over her is that she doesn't seem to care for anyone or anything the way she used to do. This troubles her, too, and she blames herself for not feeling the same toward us as she did. She has been going to different doctors all the fall and winter; some say her blood is thin, others say she has nervous prostration. That she is growing worse I don't need a doctor to tell me, but what to do for her I don't know. I have tried to persuade her to go to you before this, but she is afraid that you will find that there is something the matter with her mind.

Whatever you advise I shall try to carry out. If you think it is necessary to see her first, please let me know.

I hope she is not going to be afflicted the way her sister was. Perhaps you will recall that her sister's illness began apparently in worry over the condition of her nose, which she insisted was red and swollen, but which did not seem to us to be very much different from what it always had been. Always an extremely sensitive girl, she got the idea that everybody remarked this change in her personal appearance. In addition to her work as a stenographer, she had been studying music and had an ambition to become a public singer. After you saw her, the depression became so profound that she attempted suicide on several occasions, once by attempting to jump from the window, and at other times by turning on the gas. These acts were always accompanied by great mental excitement and followed by a sullen, moody state. She took no interest in anything, would not dress or bathe herself, and made all sorts of self accusations and queer statements. She had done something which she could neither define nor explain, but for which she must suffer. The swelling of her nose and the eruption on her face was punishment for some act which she had committed but which she could not describe. She begged me to put her in the cellar where no one could see her. At other times she would implore me to deny that she was my daughter. She would say, "You have four other girls and don't need me; make a servant out of me. I am no use to anyone; I should think you would all want me out of the way." When I was at home she would not talk very much, but whenever I went out she would begin with the other girls and talk to them by the hour about all such nonsense as I have just mentioned. We could not get her to do anything or to discuss anything or to look forward to doing anything.

About four months after we saw you, she went out with me one day to walk. We had a little store then and my husband asked me to leave a package at a certain house, the address being given in her presence. When we came near the house she said, "That is the number, that is the house over there." This was the first time she had taken an interest in anything for a long time. After walking some distance, we stopped to look at some pictures in a shop window. One picture, which particularly attracted her attention, was that of a bird, standing near a basket with a baby in it and four little girls around the basket, looking into it. She said to me, "Do you know what that is, mother? That is a stork; he has brought the baby." We then looked at a picture of Niagara and I asked her what she thought of it, and I remember she said it did not impress her very much, but she would like to see it. This was the first time she expressed a wish. One night soon after this my eldest daughter brought some work home and asked this girl if she would help her with it, as she was in a great hurry to get it out. She did not say anything, but the next day she got up early and began to work upon it and from that time she improved steadily, and in a month or so was able to go back to her work. Although she is peculiar and difficult to live with, on account of frequent outbreaks of temper, she has never had anything the matter with her since then. The girl that is sick at present thinks the friction that we have had at home with this girl probably had something to do with causing her own breakdown.

NEW YORK, February 16, 1907.

My Dear Madam:

I shall be very glad to see your daughter any day that you elect to bring her to me. You have given such a clear and explicit account of her illness that I am able to judge of its nature and say to you now what the outcome of it will be, more particularly as you have been thoughtful enough to tell me in some detail of your other daughter, who was treated by me a number of years ago. The disease that your daughter has is of the mind. If I were to say to you that it may properly be called a mild form of insanity, you might be alarmed and terror stricken. You know, however, from experience with your eldest daughter, that one may have a well-marked insanity and

recover. Therefore, you are not so likely to be frightened as one who has had no experience. Moreover, I am sure that you are not one of those foolish persons who have a latent, or well-defined, belief that insanity is a demoniacal possession or something of the nature of a disgrace. Disease is never a thing to be proud of, though it is at times difficult to be assured of this when you hear persons describing and discussing their symptoms at dinner parties and other public places. Disease of the mind is no more an admission of infirmity than disease of the body, and there is no reason why we should be more ashamed of it, or try to conceal it.

The technical name which we physicians give to the disease that afflicts your daughter is manic depressive insanity. I hasten to add that it is a very mild form of the disease, and that it will probably not progress to the degree that she will become mentally deranged, using these words now in the conventional sense.

It is only during the past few years that we have been interpreting aright patients such as your daughter. Many of them are still called cases of depressed neurasthenia, and many of them are believed to have some mysterious sort of dependency upon the specific sex functions. One of the signal contributions made to mental science in the closing years of the nineteenth century was the recognition of a mental disease whose symptoms displayed themselves in one instance by exaltation, excitement, and delirium and in another by depression, negation, and retardation. Formerly we spoke of them as mania and melancholia. Now we know that they are one and the same disease, which displays itself at one time by symptoms of exaltation, at another by depression. Another thing that we have learned about it is that the attack usually eventuates in recovery. In other words, the patient gets well, even though it cannot be said that the disease is wholly eradicated. The most important type of this form of mental disorder is that which your daughter has. She is what some would call a borderland case, but to my mind, she is a typical case slightly developed. She is of the kind that puts the physician on his metal to do something to prevent its development, and she is of the kind of which the institution physician knows little, because he rarely sees them in this stage. You have described the symptoms of the disorder so thoroughly that I shall not dwell upon them, but one feature that you emphasized interests me very much. It is the disparity between her employers' estimate of her work and her own. I have taken the trouble to inquire and they say she does her work very well. They value her services and they maintain they could not easily fill the place she has made for herself with them.

One of the earliest symptoms of the disorder is what might be called a morbid sensitiveness, or suspicion, that they are not doing their work well or satisfactorily. Another is that persons with whom they come in close contact, such as their fellow employees, recognize their unworthiness and hold aloof from them, excluding them from any participation in their amusements or confidences. Often these delusions antedate the lack of initiation and slowness of mental and physical action, which we physicians call psychomotor retardation, for a long time, and it is during this period that such unfortunate sufferers are often misunderstood. They are thought to be suffering from overwork, vapors, anemia, or "a kind of malaria." When in addition to such complaints there develop delusions of profound unworthiness which ramify from self-accusation of indescribable sins, to having bartered their soul, the suspicion is aroused that the matter is very serious. In reality it is in instances such as the two that you have had the misfortune to have had that the recognition of the true nature of the disease is so important.

Fortunately the appropriate treatment of your daughter can be carried out at home. The first thing that I wish to impress upon you is that you must be kind, tactful, frank, truthful, and patient with her. You must realize that she is ill; that the dearth of ideas which oppresses her really exists; and that the absence of spontaneous activity which she displays is genuine.

Unless you have some insight into her condition you are not the best person to help her get well. It is absurd for you to urge her to shake off her apathy, to pull herself together, to tell her that she imagines that she is worse than she really is, that she should amuse herself, etc. She has no more capacity to amuse herself or to be amused, than she has power of resolution, or the capacity to make decisions and abide by them. The mistake is so often made of dragging sufferers like your daughter to a theater, or other alleged place of amusement, of sending them to Atlantic City, of taking them to visit friends or relatives, that I ask you specifically not to do any of them.

I advise you to ask her employers to give her a vacation of two or three months. During this time try to increase her weight from fifteen to twenty pounds. To do this you should keep her in bed about two-thirds of the time, the remainder in the open air. If your house has a veranda put a couch upon it and have her lie there during the day. Surfeit her with milk and eggs, at least two quarts of the former to which a half pint of cream has been added, and a dozen or more of the latter. Don't bother her with solid food. If she asks for it let her have it. Get her to take some exercise each day, say a walk of two or three miles, and before she starts on this walk douse her with cold water, from a dipper, or slap her briskly with the end of a towel taken dripping from cold water. See that she has an adequate action of her bowels each day and if she gets "bilious" give her ten grains of gray powder in the evening followed by an aperient in the morning. You need not hesitate to repeat this in a fortnight. If her movements are inadequate, notwithstanding this, one-half a grain of cascara three times a day should be given. From your letter I infer that she does not suffer from insomnia. This is most fortunate, as sleeplessness is often a most rebellious symptom. Don't try to interest her or amuse her. Help her get well and she will do these for herself. Like the poet, such patients thrive on tranquil solitude and such society as is quiet, wise, and good. You have had an excellent lesson in this respect from your other daughter. Take care of her as solicitously as if she had typhoid fever, and you will soon have her well.

I am writing to Dr. —— of your city to ask him to go in to see her occasionally and encourage you to carry out these simple directions. When she gets well, keep her well. How is this to be accomplished, you ask? We must leave that for some other time.

Yours sincerely,

Vaccination in England.—It is stated that the duties of the public vaccinator are rapidly disappearing in many small English towns. The inhabitants avail themselves of the conscientious objectors' declaration act and therefore escape the vaccination of themselves and their children.

Correspondence.

FARM SANATORIA FOR THE TUBERCULOUS.

To the Editor of the Medical Record:

Sir:—Anent Dr. Huber's "Winning Fight Against Consumption," may I offer a suggestion to our wealthy philanthropists? It is that the next man who wants to leave twenty or thirty millions to charity endow a Tuberculous Insurance Society which shall fight the White Plague by buying farms which shall be equipped as sanatoria where the tuberculous may be treated and at the same time find occupation.

My conception of such a farm sanatorium is that it should be conducted on the plan of a Virginian estate in the days of slavery, *i.e.* raise everything it consumed and employ its own blacksmith, carpenter, wheelright, miller, weaver, etc. In other words, manufacture its own raw material for its own consumption and, as a reward for this work, care for and cure those consumptives who are too poor to pay even moderate insurance fees. These patients would correspond, in social rank, to the former slaves. The next rank, the overseer and yeoman class, would be composed of those who could pay the insurance fees; while those corresponding to the planter class would be the wealthy who could pay for luxuries and thus enable the organization to support more of the indigent.

If there were a number of such farms, the industries could be varied with the location. In the cold northern States poultry raising might be one of the chief occupations; in the west, cattle; in the far south, semitropical fruits; in Virginia and States similarly situated, apples and the small fruits, with vegetables for canning, might constitute a major occupation. The products could be exchanged between the different institutions and patients who did not do well in one could be sent to another. The principle of sick insurance, notably for consumptives, has succeeded so well in Germany that such a plan is no longer an experiment, except in so far as regards the various industries. As all of these are money-making occupations when conducted by individuals, there seems no good reason why they should not succeed even better under the auspices of a corporation.

I have not sought to give details of rates of insurance, etc., which would have to be calculated by a skilled actuary, but only to point out the salient features of a plan whose advantages appear to me obvious. We have such enormous accumulations of riches in our country that the sum of money needed, huge as it appears to a country doctor, is insignificant when compared with the wealth and proved generosity of some of our so-called plutocrats.

Gordonsville, Va. W. G. Christian, M.D.

OUR LONDON LETTER.

(From Our Special Correspondent.)

ROYAL SOCIETY OF MEDICINE—ADMINISTRATION OF SERUM BY THE MOUTH—SUPPORTS OF THE PELVIC VISCERA—GENERAL MEDICAL COUNCIL—OBITUARY.

London, June 5, 1908.

At the Royal Society of Medicine, on the 26th ult., the question of giving tuberculin by the mouth came up. Dr. E. C. Hort said he had given horse serum in 150 cases of various diseases, taking care that it was fresh and sterile. It should be taken immediately after meals. In acute diseases, as phthisis or pneumonia, he found it of little use. In hemorrhagic cases and ulcerations it was of value. In bacterial lesions it seemed to stimulate, repair, and inhibit the activity of the organisms.

Dr. Hector Mackenzie was satisfied that vaccine given by the mouth was a valuable treatment in staphylococci infections. But he was doubtful as to the value of tuberculin. In case of tuberculous glands he had known improvement follow the use of tuberculin by the mouth. He had not been impressed by its use in phthisis and did not regard the opsonic index as a feasible routine control in actual practice.

Dr. A. G. Auld thought the cases were not numerous enough to enable a conclusion to be drawn as to the value of the treatment, and suggested a possible relation between empyema in a case of pneumonia and the use of a pneumococcus serum.

Dr. Rolleston had given horse serum by the mouth, in gastric ulcer, and it stopped hemorrhage and relieved the pain as well as improving herpetic eruption of the mouth.

Dr. Lavis referred to the possibility of giving tuberculin in raw meat juice, if derived from tuberculous animals.

Dr. Vere Pearson spoke of eight cases; in three of genitourinary tuberculosis, two of them having pulmonary affection as well, he had seen some improvement. In a case of spinal caries the pain was relieved. He had two failures with horse serum for hemoptysis. In a case of phthisis with continuous fever for six months, the pyrexia ceased in three weeks under serum by mouth.

Another member spoke of horse serum locally after the mastoid operation.

In the Section of Obstetrics and gynecology Dr. R. H. Paramore challenged the statements of our anatomical textbooks as to the "Supports of the Pelvic Viscera," and said anatomical research would not settle the matter without concurrent investigation of the living processes of the body. He found no difference between condensations of subperitoneal tissue in different places and thought the visceral ligaments of the pelvis did not support the uterus. The lack of elasticity and the impossibility of yielding to pressure from above without stretching or of returning to a previous position after stretching, prevented the visceral connective tissue from fulfilling the requirements of the pelvis. He considered the abdominal and pelvic cavities as really one. In the living body they acted as antagonists to each other, and the outcome of simultaneous contraction was intraabdominal pressure.

Professor Paterson held that the structures comprising the pelvic floor were the chief factors in supporting the viscera, and any laceration or weakening of these structures predisposed to prolapse.

Mr. A. Keith said three structures are usually regarded as normal uterine supports, (1) the musculature of the floor, (2) the visceral ligament of the pelvic fascia, (3) the strong perivascular and perineural sheaths. It is not to the last the support is primarily due; they safeguard the vessels and nerves. A Hodge's pessary supports the uterus by keeping the vagina expanded and rigid, enabling the levator ani to get a hold on it.

Dr. W. E. Fothergill of Manchester maintained his previous teaching that the viscera were supported by the connective tissue intervening between them and the sides of the pelvis, the most important part of that tissue being that which formed the perivascular sheaths.

Dr. Hastings Tweedy of Dublin said Dr. Paramore had given them data which showed strong ligaments crossed the lateral fornices and could support the uterus in a normal position, and that when they were severed the cervix sagged downward, even though all the other uterine ligaments were uninjured. It was clear they kept the cervix tucked upwards and backwards. They suffer no greater strain than the liver ligaments and others similar. The levator ani essentially is the muscle which keeps the vagina from deformity and offers a counter force to the intraabdominal pressure, enabling the anteflexed uterus to lie between these forces with only slight aid from the ligaments. But if the cervix descends it cannot maintain the uterus in anteflexion, nor can it in retroflexion. A tear in the pubococcygeal fibers inevitably results in cystocele and rectocele, with slow descent of the cervix. Dr. Tweedy said he had never seen procedentia due to childbirth unless the cervix was torn, and his operative experience furnished him with further evidence of the importance of these ligaments.

Dr. Briggs of Liverpool argued on anatomical and clinical grounds that the viscera were supported by (a) the levator ani, (b) their dense pelvic fasciæ, (c) the perivascular and loose cellular tissue. The integrity of the supports did not depend on the ligaments as the integrity of a joint did not. Fascial structures were passive and maintained or restored by muscles. The widening of the linea alba during the later part of pregnancy was corrected in strong women after labor by the tonicity and reapproximation of the recti-abdominales. In operations for prolapse the restoration of these muscles and their fasciæ by extensive buried sutures should be the chief aim.

Dr. Alex. Macphail of Glasgow emphasized the distinct attachment of the levator ani to the vaginal wall, close to the cervix, and the close connection there of the pelvic fascia as important, but he thought the discussion showed a wrong tendency to assign support to one set of structures, excluding others. The via media was, he thought, the sound course from an anatomical standpoint.

Dr. M. Jones seemed to hold a similar view, and Dr. Griffiths said the pelvic fascia formed a continuous sheet of varying density and was the chief support, while the levator ani was put into action to resist special strains.

Dr. Inglis Parsons said procidentia had been known to

occur in virgins with an intact pelvic floor. Rupture of the perineum was often followed by prolapse, but not always. The ligaments in some women seemed to be strong enough to keep up the uterus without assistance from the pelvic floor, but when they were weaker this must help. He held that the intraabdominal pressure does not keep up the uterus, but is rather the chief factor in causing prolapsus.

The president (Dr. Spencer) said the section was indebted to the distinguished anatomists who had taken part in the discussion. He thought the supports were of a composite character, including atmospheric pressure, muscles, ligaments and fascia. To speak of intra-abdominal pressure was confusing, for it was really extraabdominal or atmospheric pressure—the "retentive power" of the abdomen of Matthews Duncan.

The work of the General Medical Council has continued, and most of it has been the hearing of cases of alleged misconduct. Anyone who has attended a sitting devoted to discipline must feel how unsuitable a body of this kind is to conduct such an investigation. Something like judicial proceedings might be anticipated, and there is an attempt to conduct the inquiries after the manner of a court of law, but it is rather unsuccessful. One aged practitioner's name was removed from the Register on a charge of covering an unqualified person, who was his son and had signed certificates for a school board for his father, who said he had seen the children. The chief evidence was that of two children, apparently about eight to ten, who were asked leading questions and answered yes. Also a blind man, who spoke of recognizing the voice of the accused. A competent barrister would have laughed at such "evidence." Some other names were removed from the Register, one of them on account of canvassing. This had lasted over several days, and the evidence brought forward was very contradictory, and lawyers on each side took up much of the time. The result is scarcely worth the enormous sum the sitting has cost.

Death has deprived the medical temperance cause of its most brillant leader, Dr. J. J. Ridge, M.O.H. for Enfield, and founder of the local hospital, who died on the 25th ult., aged 61. He was for twenty-one years physician to the Temperance Hospital, having been appointed on its foundation. He was also secretary to the Medical Temperance Society and editor of the journals devoted to the subject, of which he was so zealous an advocate. His position was so prominent in regard to the cause that when an international association to promote it was formed he was naturally appointed its first president by acclamation. Dr. Ridge was a student of St. Thomas's Hospital in 1864-8 and graduated at the London University, simultaneously in arts, science and medicine, taking honors in each. His writings and speeches on medical temperance in all its bearings are numerous and everywhere regarded as authoritative.

Surgeon-General Sir J. A. Hanbury died on Tuesday night at the age of 76. He obtained his first commission in 1853 and retired in 1892 after serving in China, Afghanistan and Egypt. He took part in Lord Roberts' march to Kandahar and was twice mentioned in dispatches in the Afghan campaign of 1878-80. He served in the Egyptian Expedition of 1882 and was again twice mentioned in dispatches, received the order of the Medjidieh and was promoted from the C.B. conferred in 1882 to the K.C.B.

Dr. A. Overton of Huddersfield was found dead in his bathroom on the 31st ult., having apparently died from heart failure. He qualified in 1883-4.

Dr. Dove McCalman, who practised at Oban for about twenty years and was the chief founder of the Cottage Hospital, died there on the 25th ult., in his sixty-fifth year. He was M.D., Glasgow, 1881.

OUR LETTER FROM THE PHILIPPINES.

(From Our Special Correspondent.)

SMALLPOX—CHOLERA—MISBRANDED FOODSTUFFS—PERSONALS.

MANILA, P. I., May 2, 1908.

MANILA has recently passed through a small outbreak of smallpox, which has been more virulent than would naturally have been expected under the circumstances. A number of Americans who were not protected by vaccination died of the disease, and the mortality among Filipinos has been much higher than is ordinarily the case. In this latter class, the mortality seldom goes above 10 per cent., while in this outbreak it has reached as high as 50 per cent. However, when the conditions of Manila are contrasted with those existing in some of the large cities of China and Japan, the outbreak here is comparatively insignificant. It seems quite possible that the disease among Americans may be due to infection, which is perhaps imported in silks, curios, and other articles, which are constantly brought to the Philippines from China and Japan. The outbreak in Manila, however, again affords most striking proof of the thorough efficacy of vaccination as protection against smallpox. So far, no one has been attacked who was recently vaccinated. Those who have died had either never been vaccinated or claimed to have been vaccinated when they were children, but could present no scars.

The cholera, which, during January again assumed threatening proportions, has fortunately decreased much in both numbers and virulence, and at the close of the quarter it has again almost completely disappeared from the islands. There were a total of 203 cases and 167 deaths in the city of Manila and 806 cases and 628 deaths in the provinces during the quarter. It is believed that real progress has been made during the last few months in the study of the etiology of the disease. It appears probable that cholera has become endemic in the city of Manila, and that the outbreaks in the provinces are usually due to infection which comes from here, and that it frequently happens that Manila becomes reinfected from the provinces. It now appears that the cholera organism probably exists in the sewer system of the city and possibly at times in the water supply, and that the isolated cases which occur in widely separated sections of the city and have apparently no connection with each other, are due to infection conveyed by roaches or other vermin from the sewers and esteros to easily infected food, either by means of their feet or by their intestinal discharges.

From the foregoing it would appear that as soon as new water and sewer systems for the city of Manila are completed, the chances of cholera being entirely eradicated from the islands are very hopeful.

During the first three months of 1908 220 samples of foodstuffs were analyzed, and nineteen were rejected under the provisions of the pure food and drugs act. Forty-five others were misbranded, but were released after having been properly labeled. It appears that the percentage of rejections is rapidly decreasing, and there seems to be every desire in local business circles to comply with the law. The amount of good that has been done up to the present time is simply inestimable. Butters, canned goods, beverages, etc., which have heretofore contained enormous quantities of preservatives, and, no doubt, were responsible for much sickness, are now arriving without any added chemicals, and the manner in which they keep even in this tropical climate is most convincing evidence that the presence of preservatives was unnecessary.

Dr. Richard P. Strong, of the Biological Laboratory, Bureau of Science, who has been absent for nearly a year on an extensive trip to the United States, Great Britain, Germany, and India, has returned to the Philippines, and again taken up his work in the laboratory.

Dr. A. J. McLaughlin, Passed Assistant Surgeon, United States Public Health and Marine Hospital Service, has just arrived in the Philippines, and will probably accept the position of Assistant Director of Health of the islands.

Dr. E. C. Shattuck, who for a number of years has been the physician in charge of Bilibid Prison, has recently resigned from that institution and returned to the United States, where he expects to take up the practice of his profession.

Progress of Medical Science.

Boston Medical and Surgical Journal, June 11, 1908.

Composition of Large Curds in Infants' Stools.—F. B. Talbot presents the results of our extensive series of observations. He states that large curds in infants' stools are composed of some proteid (probably casein or one of its derivatives), which on coagulating entangles the milk fat in its meshes. The amount of fat in the curds depends on the amount of fat in the milk, and as this fat increases, it replaces the proteid in the curd. The presence of large curds which has been taken by some investigators to indicate an increase of gastric HCl, can with as great probability be interpreted as indicating a lack of HCl.

Modes of Infection in Tuberculosis.—S. von Ruck discusses the relative frequency of tuberculous infection and reviews the various opinions extant on the subject. He says that the presence of the bacillus in the dust of

the air and its deposition when inhaled in the air passages remained still to be proven, after the presence in sputum of a corpuscular element had been proven. This danger from dust, however, was definitely determined by Cornet. So far as the danger from droplet infection is concerned v. Ruck does not attach very great importance to it as a mode of infection. The danger is indeed not to be minimized, but such droplets do not remain suspended indefinitely, and most of them gravitate immediately. As regards ingestion of bacilli in food, the author says it is of course possible that food may serve as a medium for infection with the bacillus of human type, but the probability that enough bacilli are introduced by its contamination with infectious dust or droplets in its preparation by consumptives, or that flies are likely to play an important part by transferring tubercle bacilli from sputum to food, would seem slight, and especially so if alimentary infection of the human subject conforms to the experience we have with the lower animals, in which enormous quantities of tubercle bacilli must be fed to produce a positive result. Quite otherwise is the case for primary infection of the digestive tract from the inhalation of infectious dust and its deposit in the pharynx or mouth whence it is swallowed with the mucus and saliva and with food and drink.

New York Medical Journal, June 13, 1908.

The Modified Blood-clot in Mastoid Surgery.—S. McCullagh describes this method in full and reports three personal cases with excellent results. He contends that this method has passed the experimental stage, and makes a plea for its more extended trial and a report of results obtained, especially unfavorable ones, so that the limits of its application may be more clearly defined. There is still room for experiment in this particular, but the writer feels that within a very short time packing of the mastoid wound in uncomplicated cases will be considered as poor surgery as a mere opening of the antrum without removal of all diseased tissue, and as justly so. He strongly urges that one or two failures be not allowed to deter from a repetition of the trial, as there is no reason why results identical with those reported should not be obtained by any surgeon who looks carefully after his technique.

An Analytical Study of Six Hundred Cases of Anesthesia.—H. L. Springer presents the following conclusions: (1) Ether and chloroform are apparently the most satisfactory anesthetics. (2) Ether is safer than chloroform, but under certain circumstances, when chloroform is desired, the risk may be materially lessened by giving oxygen with it. (3) The average patient was ten minutes becoming anesthetized, and it required two and one-half ounces of ether to obtain this condition. (4) The average length of time of the operation was one hour and a quarter, and it required five and one-half ounces for this time, or, in other words, about six ounces were used during the first hour, and about three ounces for the second hour. (5) While most of the evidence at hand points in favor of vomiting being due to a centric disturbance in ether anesthesia, these records show a close relationship between excessive secretion of mucus and vomiting. (6) In the treatment of accidents most dependence may be placed upon ammonia in the form of inhalation and oxygen. (7) The more remote consequences of anesthesia, such as status lymphaticus, acetonuria, acidosis, hepatic toxemia, etc., must not be lost sight of, and general anesthesia should be preceded by a thorough examination of the heart, lungs, and kidneys.

Pruritus Ani.—R. D. Mason discusses this affection with special reference to its cause and treatment by the *x*-ray. In his opinion the disease is caused in the great majority of cases by an unnatural discharge of moisture about the parts. In chronic cases the cause may have disappeared, or if present its removal may not end the trouble, as the skin has become so thickened and thrown into folds that only its destruction or removal will effect a cure. The irritation that causes the catarrhal discharge may be internal or external hemorrhoids, chronic proctitis, ulceration, fistulas, especially the small submucous variety with no external opening, pin worms, hard, dry feces which irritate the parts, the lodging of irritating matter in the so-called rectal pockets, the growth of small polyps, or, in fact, anything that will cause an irritation. The *x*-ray treatment is of especial service in the old chronic cases in which the skin is thickened and eczematous. His method is as follows: With a soft tube he gives an exposure of ten minutes' duration twice a week, until he learns how the skin is going to stand it. If there is no irritation he gives three treatments a week until a brown discoloration appears. All treatment is then stopped until this goes away, when treatment is resumed until it reappears. This is usually enough, but, if possible, he thinks it is well to give an occasional treatment after this as a matter of precaution. The results are most gratifying, but it is too soon to predicate their permanency with absolute certainty.

Journal of the American Medical Association, June 13, 1908.

Indolaceturia.—C. A. Herter finds that indolaceturia, or the presence of indolacetic acid in the urine in appreciable amount, is not a rare occurrence, and is usually associated with pathological conditions in the intestinal tract. It is detected by the rose-red urosein color reaction on the addition to the urine of an equal volume of concentrated hydrochloric acid with, if necessary, one or two drops of a 0.1 per cent. solution of potassium nitrite. It is necessary that the urine should contain a suitable oxidizing agent which is usually furnished by the nitrites formed by the action of nitrifying bacteria in the urine, hence a urine in which the urosein reaction fails in a fresh condition may give it without the addition of a nitrite after standing 24 or 48 hours. Indolaceturic acid to the amount of from 0.001 to 0.01 per cent. in the urine is readily shown by this method: a lesser amount can be detected by making an ethereal extract. Urines containing a large amount of indican develop indigo by oxidation with nitrites so as to obscure the reaction dependent on indolaceturic acid. The indigo that is separated may advantageously be removed from the solution by shaking with chloroform. In a few cases he has seen the mere addition of concentrated hydrochloric acid to the urine of children suffering from severe gastroenteritis, followed by the appearance of an intense greenish-blue or blue color, due to the presence of indigo. In such cases the excess of hydrochloric acid has always been great. The most pronounced cases of indolaceturia observed by Herter have been in urines from patients with diabetes, typhoid fever, or chronic enteritis. He has also observed a strong reaction in some cases of jaundice, and he believes that small quantities of indolaceturic acid are present in chronic digestive disorders. Other observers have noted the urosein reaction in pulmonary phthisis, chlorosis, osteomalacia, nephritis, carcinoma, gastric ulcer, vomiting of pregnancy, and perityphlitis. He thinks it clearly desirable that routine examinations for indolacetic acid should be made, and that a record should be kept of the relationship existing between the intensity of the reaction for indolacetic acid and the intensity of the reaction for indigo blue. Like indol, indolacetic acid is the result of the decomposition of tryptophan in the intestine, and there appears to be a sort of reciprocal relation between them, each being apparently exclusive of the other to a certain extent. The reason for this apparent selective action is not clear, but Herter thinks that the careful study of the symbiotic action of bacteria on this substance may in time reveal it. The excessive ingestion of proteids seems to be connected with the formation of indolaceturic acid, hence its frequency in diabetes. While it is not Herter's intention to discuss the pathological consequences of indolaceturia, he suggests, since it is not paired in the organism like indol, skatol, and phenol, it may have an opportunity to act directly on the nervous system when absorbed in considerable quantities. Its study is, therefore, desirable.

The Larynx and Tabes.—W. Freudenthal gives the results of his examination of the patients at his command in the Montefiore Home. The general conclusions are summed up substantially as follows: 1. The larynx is frequently the seat of serious affections in tabes. 2. Laryngeal crises are so often met with that they are almost of pathognomonic significance. 3. Unilateral and bilateral paralysis of the postici are the affections *par excellence* in tabes, but a unilateral paralysis of the recurrent nerve, often with the vocal cord in a hyperabducted position, as mentioned by Harland, is nothing uncommon. 4. The abductor fibers of the recurrent laryngeal nerve are affected primarily in tabes as well as in multiple sclerosis. 5. The voice in tabetics is often not changed, in spite of extensive lesions. 6. In order to reach a positive diagnosis all these cases have to be observed for a considerable period. 7. In multiple sclerosis there is frequently a subjective dyspnea that cannot be explained by the objective signs.

Kidney Excretion.—Edwin Beer reports seven cases which he thinks demonstrate that a diseased kidney may so affect the excretory activity of the other kidney as to mislead all who rely too much on our present functional tests. This is exclusive of the usually temporary and probably reflex, oliguria or anuria of the second kidney in obstructive conditions of the diseased side, and the degenerative changes or so-called toxic or sympathetic nephritis induced by the disease of the other kidney. In the reported cases he used the phloridzin test which, in normal cases causes glycosuria, and found that the diseased organ so influenced the other that the latter failed to excrete sugar so long as the diseased kidney remained in the body.

After nephrectomy the reaction was normal in three cases and after nephropexy in one. Two of the patients died, and in one the operation failed to relieve the condition on the diseased side, but in all three the insufficiency of the other kidney indicated by the phloridzin test did not exist. These cases point to but one conclusion, *i.e.* that a diseased kidney may so influence the second organ as to make it appear gravely diseased. Somewhat similar observations have been reported by Rovsing and Kapsammer; and Albarran, Koranyi, and C. Wilbrecht have noticed the improvement in function of the second kidney following relief of diseased conditions in the other. From all the facts Beer concludes that there is probably a factor underlying functional tests that has not been sufficiently emphasized in the past. He does not discuss the question whether this influence is toxic or reflex, or both combined, but until it can be estimated, he says, all functional tests of the excretory activity of a kidney are misleading.

Adenoid Infections in Adults.—Alice G. Bryant calls attention to the streptococcic infections of the pharyngeal adenoid tissue in adults, and the importance of "direct examination of the postnasal and nasal regions to settle any debated question when septic conditions are present that cannot be attributed clearly to some one definite region of the body." The advisability of having bacteriological examinations made of these regions in such cases is also suggested. Three cases are reported out of ten which have come under her observation. The ages ranged from 30 to 50 years. In all there was a pronounced streptococcic inflammation of the postnasal adenoid tissue, with mild septic symptoms which disappeared with the clearing away of the broken-down tissues, disinfection, and appropriate general treatment.

Eyestrain and Tuberculosis.—Recognizing the frequency of opportunities for tuberculous infection and its prevalence as shown by post mortems, F. Parke Lewis reasons that some other element than that of infection must influence the mortality from this disease, otherwise the world would become a mortuary from this cause alone. He includes eyestrain among these factors, and claims that it can so derange the nervous functions as to produce gastric and intestinal derangements that can so lower the vitality and diminish resistance as to retard recovery from pulmonary tuberculosis. The essential propositions of his thesis are summed up as follows: "1. The inadequacies of focus or the motility of the eyes may give rise to and be responsible for disturbances of digestion and assimilation. 2. Lowered vitality, especially in the neurotic, predisposes to tuberculous infection, and as superalimentation is of first importance in effecting a cure, an exact and complete examination of the refraction and of the motility of the eyes should constitute an essential part of the examination of every patient suspected of having the disease. 3. If these are the views of the ophthalmologist on this subject they are of such vital importance to a vast number of sufferers that resolutions to that effect should be adopted and the recommendation made to this Association that it is the sense of the members of this section that no examination for tuberculosis can be considered complete until it shall include the refraction and the motility of the eyes."

The Lancet, June 6, 1908.

Antirabic Serum, and the Rabicidal Properties of the Serum of Patients After Undergoing Antirabic Treatment.—The conclusions of an elaborate paper by D. Semple are as follows: (1) By immunizing horses with fixed rabies virus it is possible to prepare a serum having well-marked rabicidal properties. Normal horse serum is devoid of these properties. (2) The rabicidal properties of this serum can be tested by mixing it with fixed virus and subsequently using the mixture to inoculate susceptible animals, such as rabbits, subdurally. (3) The indications for the use of such a serum would seem to be as an adjunct to the ordinary method of treatment in severely bitten and late cases. In severely bitten cases coming early for treatment it might also be injected into the wounds and the tissues in their vicinity. (4) The serum of patients after undergoing a course of antirabic treatment also gives evidence of containing rabicidal substances and the presence of these substances can be demonstrated in a manner similar to that mentioned in Conclusion 2. Normal human serum is devoid of these properties. (5) The rabicidal substances in the serum of a patient after antirabic treatment are a possible index of the amount of immunity conferred and the efficacy of treatment. (6) Prolonged treatment confers a higher degree of immunity, as judged by the rabicidal effects of the serum or fixed virus, than treatment extended over a shorter period of time. (7) The blood of a patient suffering from hydrophobia fails to infect rabbits when inoculated subdurally. (8) The serum of a patient in the early stages of hydrophobia is capable of prolonging the incubation period for fixed virus when mixed *in vitro* and inoculated subdurally in rabbits.

A Case of Indicanuria.—G. N. Montgomery reports one case of interest from (1) the deep color of the urine, (2) the fact that it was colored when passed, and (3) the fact that the patient appeared to be in good health. The history is as follows: Patient is a woman 32 years of age, hospital servant. Her general health is good except that she suffers at times from slight attacks of "petit mal." She says that she often has "trouble with her bowels," having to take pills sometimes to obtain an action. On a certain day, having been constipated for several days, she took a pill of colocynth and hyoscyamus. This was her usual aperient. On the following day the bowels were relieved twice, and she experienced some abdominal discomfort during the day. On this date the patient noticed that the urine was altered in color, and a specimen was brought to me. The color varied in density during the following three days, when it became much lighter, and on the next day it was quite normal. During these days the patient did her work as usual, and felt quite well, except that she felt a little worried about the urine, which was colored when passed. She had never passed urine like it before, and has not done so since. The urine was of a dark blue-green color, with a specific gravity of 1015; it was acid; there was no albumin or sugar. On adding a little chloroform to some urine in a test tube the chloroform became a blue color. When some urine was added to some boiling nitric acid a bluish ring was seen at the junction of the two liquids. There was no history of eating or drinking anything that she had not been accustomed to or of using carbolic acid in any form, or methylene blue.

Suprarenal Hemorrhage in an Infant; Its Relation to Hemophilia.—B. G. Morrison was in attendance at the birth of a full-term male child born after a normal labor. The umbilical cord, a thick one, was tied three times in succession on account of bleeding at the seat of ligation. This was finally checked and the child did well till the ninth day, when it became weak and jaundiced. In a few days more bright red patches appeared on the chin and later on various bodily areas. Fever and slight convulsions came on, and the child died on the twentieth day. Autopsy revealed a dark, slate-colored left adrenal. Opened *in situ*, it collapsed at once and emptied its fluid contents into the abdomen. On examination it appeared to be converted into a blood sac, was very soft, and partly torn in removal. There were no signs of inflammation spreading up from the umbilicus, and the umbilical cord inside the abdomen was small, pale, and evidently not diseased. The brain was not examined. The microscopic report was as follows: "The right suprarenal shows no abnormal appearances. The left suprarenal is much broken up, but there are the remains of hemorrhage in its medullary substance, both in the form of extravasated corpuscles and as granules of pigment. The condition is probably the result of strain, and not of disease." The author says that the case is typical of hemorrhage into the adrenal medulla, and its character was verified by the necropsy. It appears to him that its chief interest and significance depend upon those earlier evidences of failure of the vasotonic function of the medulla which have been described; the signs of a hemophilic weakness, the general atony, the slight preliminary purpura, and increasing lassitude which culminated in the final purpuric explosion, nervous and general collapse. It appears as if there had been present at birth, or possibly before it, in the medulla, some premonitory congestion or slight hemorrhage, followed by a sudden final apoplexy, a condition of things which finds its counterpart at the opposite extreme of life in the cerebrum. How far hemophilia is dependent on adrenal inadequacy remains to be proved, but the present case is suggestive in this connection. There was no family history of hemophilia.

British Medical Journal, June 6, 1908.

Large Thymus; Sudden Death.—D. F. MacIntyre was called to a child, found dead on arrival. It was three months old, nursed well in the evening, but early the next morning died suddenly in a convulsion. Autopsy revealed a large thymus extending nearly the whole length of the sternum and adherent to the pericardium and pleura on both sides. It extended back to the vertebræ and seemed to occupy a large part of the thorax. The heart and lungs were healthy, but displaced by the thymus. Liver and spleen were enlarged, the former noticeably so. Stomach and intestines were normal. The left kidney was somewhat enlarged, as were both adrenals. The thyroid gland was slightly enlarged. The brain was rather soft; the pineal gland was enlarged. Death was doubtless due to pressure by the enlarged thymus on the pneumogastric.

Plastic Resection of the Breast and Its Bearing on the Preliminary Incision of Breast Tumors.—C. H. Whiteford's conclusions are as follows: (1) Every breast tumor should be incised prior to its removal. The surgeon, who, in performing a radical operation for supposed malignant disease of the breast, neglects the elementary precaution of incising the tumor as a means of either confirming or disproving the diagnosis, runs the risk of finding himself in the unenviable position of having performed Halsted's or some equally extensive operation for a simple tumor, such as adenoma or abscess. (2) The exploratory incision should not be made through the skin which overlies the tumor. An incision made into the tumor through the overlying skin, in the event of the tumor proving nonmalignant and needing only local removal, results to a certainty in a scar and probably in a depression. This scar, or scar plus depression, if situated in the upper half of the breast, interferes with the wearing of a low-necked dress. (3) For exploration of, and if innocent for removal of, tumors situated in the upper hemisphere of the breast, the incision and method of Collins Warren should be employed, because, in the event of the tumor proving innocent and needing simply local removal, this method prevents a disfigurement which, to a sensitive patient, is distressing and, surgically, is unnecessary.

Berliner klinische Wochenschrift, June 1, 1908.

Pepsin in the Urine.—Wilenko studied the excretion of pepsin in the urine, using a modification of the method of Jacoby and Solms. In every case he worked with twenty-four hour specimens, and compared the quantities obtained with those secreted by the stomach. The excretion of pepsin by the urine was found to vary from day to day in a healthy person without any apparent connection with the diet. In examining patients with diseases of the stomach it was found that the pepsin of urine depended in the quantity of excretion not upon the amount secreted by the stomach, but upon the amount taken up by the lymph and blood-vessels. Some of the experiments suggest the existence of a pathological condition, in which the mucous membrane had lost the capacity of secreting pepsin into the cavity of the stomach, but yet retained the capacity to supply the body fluids with it.

Complement-binding Substances in the Urine of Syphilitics.—Blumenthal and Wile have examined fifty urines, forty-one of which belonged to syphilitics, in an attempt to decide whether the substances responsible for Wasserman's specific serum reaction in syphilis were excreted by the urine. The results were controlled by a parallel examination of the blood for the same reaction. Of the forty-one urines of the syphilitics thirty-one gave a positive reaction, analogous results being obtained with the blood of the same patients. In six cases both results were negative. In three cases the serum gave a positive reaction, while the result with the urine was negative; in two cases the serum gave a negative result and the urine a positive one. Of the nine control cases the results were negative for both serum and urine in eight, while in a case of scabies the reaction with the serum was negative and with the urine slightly positive. The reactions with the serum were more marked in the majority of the cases. The authors consider it proved that the substances found in the serum may frequently appear in the urine, but are not ready to say how far such examination of the urine may help in the diagnosis of syphilis, the number of cases not being large enough for a final judgment.

Münchener medizinische Wochenschrift, June 2, 1908.

Spirochetes in Mouse Tumors.—Deetjen found spirochetes in all strains of the tumors of mice studied in the Heidelberg Institute for Cancer Research. The examinations were made for the most part with fresh specimens. The blood was also shown to contain these organisms when special illumination of the microscopic field was used. The spirochetes have motion in fresh preparations, and for some twenty-four hours they retain their corkscrew-like form. After that they assume another form which is much harder to see. The smear preparations are stained red with Giemsa's stain, the organisms being one and a half to five microns long and showing one to five turns. Flagella could be demonstrated in many specimens. In sections the spirochetes were easily shown by the Levaditi method. They were especially abundant in the connective tissue just beyond the tumor. One series did not show the presence of this organism, and the author concludes that it can have nothing to do with the growth of the tumor. No spirochetes were found in six cases of carcinoma in the human beings, nor in the case of a sarcoma of a rat. Deetjen thinks that the spirochetes seen by Gaylord, Borrel, and others may have been identical with the organisms observed by him. While denying direct etiological importance to these structures, he considers that they stand in some close relation to the appearance of the new growths.

Histological Changes in Pernicious Anemia.—Schatiloff has examined the organs from four cases of pernicious anemia, using the most modern stains, such as Giemsa-Romanowsky, May-Grünwald, etc. His results corroborate the findings of Meyer and Heineke. In all four cases the spleen showed myeloid hyperplasia; in one case the lymph nodes showed a similar picture, though of a lesser extent; the livers showed no such changes. Special attention was given to the changes in lymph nodes, and a hyperplasia of the lymphatic tissue was never seen. Indeed, the lymphatic follicles of the spleen appeared diminished, the liver and the bone marrow showing no lymphatic nodules whatever. A pernicious anemia can never, therefore, pass into a leukemia, as has been suggested. Cases interpreted in this way were probably in the aleukemic state of leukemia. In the bone marrow the author frequently found nongranular cells, probably myeloblasts; megaloblasts and megalocytes were also frequently met with.

Deutsche medizinische Wochenschrift, May 28, 1908.

Early Operation in Cholecystitis.—Riedel says that the ideal treatment of acute cholecystitis of the graver type should be analogous to the treatment of appendicitis. The gall-bladder, with the gallstones, should be removed, the operation at this stage being less difficult than later, when adhesions are formed and the condition of the patient is made worse by the chronic disease. Early operation prevents the possibility of perforation of the distended gall-bladder, as well as the dropping of a stone into the common gall-duct. He operated upon thirty-two patients in their first attack, and lost only those patients who suffered with such serious complications as thrombosis of the aorta, double pneumonia, thrombosis of the portal vein, etc. Light cases of cholecystitis should be treated conservatively until the diagnosis is made sure of, and then operation should be advised, as the danger of a severe attack is always present.

Local Anesthesia in Prostatectomy.—Lanz says that the use of a catheter in prostate hypertrophy is contraindicated, for in the long run it always leads to infection of the patient. Transvesical prostatectomy is the best operation for the condition; under lumbar anesthesia it is no more dangerous than catheterization, and leads to a radical cure of the disease. In selected cases the operation may be performed in two stages, and in very old or weak patients the second part, the shelling out of the prostate, may be done without any anesthesia. In three cases of the author the procedure was almost painless. In eight other cases the prostate was removed at one operation.

Professional Gratitude.—There dwells in Bombay a medical man who takes an altogether too liberal view of the claims of gratitude which his patients have upon him. He does not feel satisfied with personally assuring them of his sensibility of their friendly support, but has let his feelings on the subject overflow into the columns of a native paper published in the Gujarati dialect, his effusion curiously enough being headed by a portrait of himself with a stethoscope prominently displayed. We are indebted to a correspondent for a translation of this precious thanksgiving, of which we have space to give only a few extracts. "Dr. —— hereby thanks his thousands of patients for the good feeling they showed and the blessings they poured on him during his last illness of typhoid fever." (Here follow details of the enormous amount of work which brought this illness on him.) "I hereby thank all those of my patients in Bombay as well as in other countries who at that time expressed their good wishes and blessed me. . . . At the same time, during the typhoid illness, a very sad and imaginary rumor that my death had taken place, first propagated by some enemy of mine, spread very rapidly all over India, so that many people from Bombay, as well as outside, owing to the good feelings they had toward me, came to my place to learn the truth, and hearing that the rumor was false, returned, showing their scorn for the spreader of the false rumor and blessing me. And Parsees, as well as people of other communities, had ceremonies performed for my recovery."—*The Lancet.*

Book Reviews.

Modern Medicine. Its Theory and Practice. In Original Contributions by American and Foreign Authors. Edited by William Osler, M.D., Regius Professor of Medicine in Oxford University, England, Honorary Professor of Medicine in the Johns Hopkins University, Baltimore, Formerly Professor of Clinical Medicine in the University of Pennsylvania, Philadelphia, and of the Institutes of Medicine in McGill University, Montreal, Canada. Assisted by Thomas McCrae, M.D., Associate Professor of Medicine and Clinical Therapeutics in the Johns Hopkins University, Baltimore. Volume III. Infectious Diseases (Continued). Diseases of the Respiratory Tract. Illustrated. Philadelphia and New York: Lea Brothers & Company, 1907.

The third volume of this system opens with an interesting chapter by Col. David Bruce on a disease American physicians have no opportunity of studying—Malta or Mediterranean fever. The author believes that in Malta at least nine-tenths of the cases of the disease are due to the use of milk from infected goats, and that there is good prospect of the malady being entirely driven out by proper preventive measures. The succeeding chapter is on another exotic disease, beriberi, and is written by Dr. Maximilian Herzog, whose observations in Japan and the Philippine Islands lead him to the view that the disease is not caused either by any of the dietetic factors alleged in such numbers, nor by the coccus isolated by Okata and Kokubo, though it probably is an infectious malady. Dr. M. Ravenel contributes the three chapters on anthrax, rabies, and glanders which are satisfactory expositions of these subjects, though in discussing the treatment of anthrax the immobilization method, by which results have been obtained comparable to those of radical surgical procedures, might be deemed worthy of mention. Tetanus has been allotted to Dr. James M. Anders, the gonococcus infections—a subject whose importance appears to be steadily growing—to Dr. Rufus I. Cole, and leprosy to Dr. Isadore Dyer. The succeeding five chapters on tuberculosis are without doubt the most important in the volume and deserve the highest praise. The first of these, in the history and etiology, by Dr. Edward R. Baldwin, and the last three in the symptoms, diagnosis, prophylaxis, and treatment by Dr. Lawrason Brown are fitting exponents of the admirable work being done at the Saranac institutions, while Dr. MacCallum's essay on the pathology is also excellent. The chapter on syphilis by Dr. Osler and Dr. John W. Churchman is of course stamped with authority. Part one of the volume closes with a discussion by Dr. Thomas R. Boggs of the infectious diseases of doubtful nature such as febricula, glandular fever, etc. The second part of the volume is devoted to diseases of the respiratory tract, beginning with a chapter on the mechanics of respiration by Dr. Thomas R. Brown. This is followed by one on the nasopharynx, pharynx, and tonsils by Dr. Francis R. Packard and by one on hay fever by Dr. W. P. Dunhar in which that author presents his well-known views on the etiology, and the results in the serum treatment, of this disorder. Dr. H. S. Birkett writes on the larynx, Dr. A. McPhedran on the diseases of the bronchi, Dr. Hobart A. Hare on those of the lungs, and Dr. Frederick T. Lord on the affections of the pleura. Chapters on pneumothorax and the diseases of the mediastinum by Dr. Walter B. James and Dr. Henry A. Christian respectively close the volume, which is well in conformity with the standard of its predecessors.

Christian Science, The Faith and its Founder, by Lyman P. Powell, Rector of St. John's Church, Northampton, Massachusetts. New York and London: G. P. Putnam's Sons, 1907.

For that class of people to whom facts prove nothing and whom evidence does not convince, this singularly fair and honest book will have been written in vain, but to all others its conclusions must surely be invincible. Its writer has not only availed himself of all possible sources of information, but has also taken the trouble personally to verify these sources. He acknowledges the good in Christian Science, but points out to his readers that "the same good is to be found in all other religions and therefore asks for no special emphasis, while the evil is distinctive and needs analysis and publicity to make it evident." This evil the author attacks in three separate indictments. First, that when members of any Christian Church turn to Christian Science, they usually turn away from historic Christianity. Second, that there are in the theory of Christian Science certain structural weaknesses which may be easily overlooked by people unschooled in philosophy, theology, or science. Third, that the answers of the accredited exponents of the movement to the criticisms of outsiders satisfy none save Christian Scientists and such others as read carelessly and think loosely. These several indictments are driven home with the masterly precision of the clear thinker and trained scholar. The medical profession, naturally, finds the psychology of Mrs. Eddy herself less of a problem than do the laity, but Dr. Powell proves himself fully equal to it, and the chapter headed "The Founder of the Faith" is as entertaining as an analytical novel. Although the archetypical neurotic, plus keen business instincts and an iron will, she is also a woman, old and frail, and for all its ruthless dissection the book has no unkindly word for her as such. One could heartily wish that this volume, together with Miss Milmine's articles published by McClure, may be considered a final summing up of this vexed question, for all clear-headed people.

The Diagnosis and Treatment of Pulmonary Tuberculosis. By Francis M. Pottenger, A.M., M.D., Monrovia, California. Medical Director of the Pottenger Sanatorium for Diseases of the Lungs and Throat, Monrovia, California; Professor of Clinical Medicine, Medical Department, University of Southern California; Chief of Medical Staff of the Helping Station of the Southern California Anti-Tuberculosis League, Los Angeles, Cal.; Fellow of the American Academy of Medicine; Member of the American Climatological Association; Member of the American Therapeutic Society; Corresponding Member of the International Anti-Tuberculosis Association, etc. New York: William Wood & Co., 1908.

In this volume the author essays to give a full discussion of the early and late diagnosis of pulmonary tuberculosis as well as of the treatment in the light of modern studies in immunity. In the section on Early Diagnosis will be found not only a discussion of the clinical signs and symptoms, but the various methods employed in diagnosing the disease, including special methods used by the author. Among the latter is the elastic tube percussion method, which has no doubt in his hands proven useful, but which would, we fear, in the hands of the general practitioner prove of little service as an aid to diagnosis. New instruments and methods are worthy of trial by experts, but what is needed more by the nonspecialist are adequate training and practice with those already in our possession.

The various methods of treatment and their underlying principles are discussed and it is of interest to note that the author has taken a rather decided stand against the prevalent fashion of over-feeding and hypernutrition. He says: "If we were to discover a scientific dietary for people in health, I do not think it would be far from that required in treating tuberculosis." The section on specific treatment deals with the various bacterial products, also the various theories as to the action of tuberculin and the allied substances. Statistics from various sources are given bearing on the different phases of the subject. A brief sketch is devoted to Bier's hyperemic method.

We miss in this work a full discussion of certain subjects of recent interest, such as the conjunctival and cuticle reactions, but the book satisfies many of the demands of popularity in that it is concise and of convenient size.

Injuries of Nerves and Their Treatment. By James Sherren, F.R.C.S. Eng., Assistant Surgeon to the London Hospital; Surgeon to the Poplar Hospital for Accidents; late Erasmus Wilson Lecturer, Royal College of Surgeons. New York: William Wood & Company, 1908.

The author states in his preface that his manual is intended as a guide to the examination and treatment of cases of nerve injury; and, while not claiming that it is an exhaustive account of the subject, he believes that it includes all that is essential to this end. The material used is taken largely from papers previously published in *Brain* (with Dr. Head), and in the *British Medical Journal, Clinical Journal*, and the *Lancet*. The method of production of nerve injuries is first described, then the various symptoms resulting from complete and incomplete division of a nerve, differential diagnosis, treatment, and methods of recovery. The examination of the patient is carefully detailed; the results of Dr. Head's recent investigations on sensation are utilized; and, for muscle testing, Dr. Lewis Jones's book on "Medical Electricity" is frequently referred to. Very little further reference is made in the book and it would seem as though the work of certain American investigators in nerve palsies (Frazier and Spiller, Clark and Taylor, and others) had not been given full credit. The entire work, however, abounds with carefully detailed and reliable diagnostic hints. A possible criticism might be that actual operative technique could have been more fully explained and illustrated.

Society Reports.

AMERICAN MEDICAL ASSOCIATION.

Fifty-ninth Annual Session, Held in Chicago, June 1, 2, 3, 4, and 5, 1908.

(Special Report to the MEDICAL RECORD)

(*Concluded from page* 1056.)

SECTION ON OBSTETRICS AND GYNECOLOGY.

Wednesday, June 3—Second Day.

The Preparation for and After-treatment of Abdominal Section.—Dr. H. T. BYFORD of Chicago presented this paper. Although there was a great disparity of opinion on these points, the author thought that the tendency of the present day was toward simplicity. The amount of preparation depended on the patient. Thus, an emaciated woman, with bleeding from a uterine tumor, who had traveled a long distance to get to the hospital, would require from a few days to a few weeks of preparation, while a strong young woman who entered the hospital for some slight vaginal operation would require almost none. These examples showed the futility of trying to fix upon some one routine treatment which should be applicable to all cases. The same might be said in regard to the after treatment. Each case must be treated on its own merits.

Dr. D. H. CRAIG of Boston agreed that there should be no routine preparatory treatment. As to post-operative nourishment, the patient's own desires should be the guide to the amount of food allowed. He had also followed the same rule in allowing patients to leave the recumbent position. This freedom was allowed, however, only when there was no actual physical reason against it.

Dr. HALL of Cincinnati thought that patients should be put into the best possible physical condition before they were subjected to operation.

The Care of Patients after Abdominal Section—Dr. C. C. FREDERICK of Buffalo believed that it was unwise to allow patients to assume the upright position in less than sixteen to eighteen days after an abdominal operation. His reasons were that the liability to hernia was greatly increased by curtailing the length of time spent in the recumbent position. He thought, too, that most patients were in a state of reduced bodily vigor at this time and that they really needed a rest of two or three weeks. Of course, this did not hold true for robust people operated on for some acute condition.

Dr. H. J. BOLDT of New York did not believe that a routine could be settled upon which would be suitable to all cases. He had been doubtful about letting these patients get up early in their convalescence until he had tried the experiment and had seen the beneficial results which always followed. Hernia, he thought, was not due to early getting up, but rather to the old method of suturing. He was positive that an early return to the upright position and freedom in diet, if they were warranted by the patient's physical condition, would invariably afford an earlier and a better convalescence.

Dr. RIES of Chicago said that he had tested early mobility in over a thousand cases of abdominal section and had not yet seen a hernia result in any case where the abdominal wall had been properly sutured and where union had taken place by first intention. Among other advantages, the most important were that pulmonary complications were almost unheard of, thrombosis and embolism were rare, catheterization of the bladder became unnecessary, evacuation of gas from the stomach and bowels was easier and freer, and the improvement in the appetite and in the general condition was most remarkable.

Dr. AUGUST MARTIN of Greifswald, Germany, thought that patients should be allowed to move about as soon as they liked. He did not object to their sitting up on the third or fourth day, or getting out of bed by the end of the first week. He would not really object to their getting out of bed even earlier than this. However, he did not hurry them, rather allowing them to follow their own inclinations. Post partum cases he did not keep in bed as long as he did formerly. Here, of course, the problem was a quite different one, because of the condition of the uterus. The time which he advised them to stay in bed depended upon whether they were able to do nothing after getting up or had to go back immediately to their domestic duties.

Dr. FREDERICK closed the discussion, still maintaining that there was a class of women who must remain in bed for a considerable time after operation, and that this class should not be confounded with those who were able to get up early.

Ruptured Tubal Pregnancy.—Dr. HUNTER ROBB of Cleveland presented a paper with this title, with the subheading, "When shall we operate?" This speaker believed that early operations were responsible for many deaths. He was convinced that shock was the real condition from which these patients were suffering, and that it was this shock rather than hemorrhage which was responsible for their condition. This, he thought, might be partly proved by the fact that their state became grave more rapidly than it could do if hemorrhage were the cause of it. The physiologists said that a human being could lose 3 per cent. of body weight in blood without any very serious damage, and he questioned very seriously whether more than this was ever lost by the rupture of a tubal pregnancy. It had been his experience that active bleeding had ceased by the time the tube could be gotten at and ligated. The patient, therefore, was not bleeding to death, but was in a condition of shock, and he believed that a wholesome reaction should be allowed to set in, aided in its advent by stimulants, saline infusions, and the application of weights or pressure to the abdomen before an operation was attempted. Otherwise we should be in danger of adding shock to shock. None of his twenty-five patients had been operated upon earlier than twenty-four hours. The time had varied from three to twelve days after rupture, with an average interval of five days. Twenty-nine experiments on dogs had shown that hemorrhage stopped before a fatal termination ensued, even when vessels so large as the uterine and ovarian arteries had been severed. In making this statement he had not lost sight of the fact that dogs stood bleeding better than human beings. The experiments had shown that clotting took place in from fifteen to twenty minutes and that there was no danger of dislodging the clots by the administration of intravenous infusions.

Dr. C. C. FREDERICK of Buffalo had found from personal experience that only 5 per cent. of the cases were accompanied by hemorrhage severe enough to threaten a fatal issue. Therefore, in 95 per cent. of cases the control of the hemorrhage might safely be left to nature's conservative methods; 5 per cent. of the patients would die if left alone, and they would probably die if operation was done. He believed, however, that they should be operated upon on the chance that operative intervention might save them.

Dr. CARSTENS of Detroit said that more people were dying now of appendicitis under conservative treatment than had died ten years ago under less conservative measures. The important point to be determined was whether a tube had actually ruptured, or only aborted. He did not know any way of finding out. If he could tell he would wait in cases of tubal abortion and operate in cases of tubal rupture. He thought that cases were common in which there were successive ruptures and that the shock was due to this increasing loss of blood. He did not believe in washing out all the blood and attempting to ligate the tube. He thought it better to go down through a small incision, clamp the tube and wait.

Dr. MASSEY cited two cases that had ended favorably

without operation. In one of them the subsequent absorption of the blood was aided by electricity.

Dr. Hall of Cincinnati thought that patients *in extremis* were more apt to die if operated upon than if treated expectantly. He had reported such a case of a patient who had been operated upon sixteen days after rupture, in whom perfect recovery resulted.

Dr. Noble of Indianapolis thought there was danger that the general practitioner would misinterpret this paper. He feared it at the same time that he admired it.

Dr. D. Tod Gilliam of Columbus thought that if one were going to operate at all, there was greater danger in a delayed operation than in one performed immediately and quickly, in the Trendelenburg position. He knew of an unoperated case in which death occurred frem hemorrhage.

Dr. Henry Banga of Chicago expressed his belief that the outlook depended upon whether the rupture took place into the broad ligament or cul-de-sac of Douglas (in either of which events hemorrhage would soon stop spontaneously), or whether it took place into the abdominal cavity, where it would not be so checked. In a patient with a history pointing to a ruptured tubal pregnancy, if the uterus was found in the median line, it was probable that bleeding was going on into the peritoneal cavity.

Dr. August Martin of Greifswald did not agree with Dr. Robb. It was a cardinal rule in surgery to secure a bleeding vessel, he said. He had seen at autopsy women who had died of tubal abortion. Statistics that he had been collecting year by year spoke more and more insistently as time went on for early operation, and he thought that of late years the general opinion had been in favor of early operation. It had been his experience that shock was diminished as soon as the bleeding vessel was secured.

Dr. Campbell of St. Joseph had believed for some time that it was not possible for a patient to bleed to death from the rupture of a tubal pregnancy. It had been his custom to wait from twenty-four to forty-eight hours, and out of five cases treated four had rallied from the shock and recovered from the operation. The fifth patient, who refused operation for four days, died of ileus after operation. He thought that in waiting too long there might be danger of peritonitis.

Dr. McDermott of Chicago thought that the blood should be allowed to escape slowly from the abdominal cavity through a small incision in the peritoneum, thus avoiding any rapid change in intraabdominal tension.

Dr. Theinthaus of Milwaukee expressed his belief in immediate operation.

Dr. Henry of Omaha thought that operation should be resorted to immediately and abdominal pressure applied.

Dr. I. S. Stone of Washington favored immediate operation, preceded by saline infusion.

Dr. Robb, in closing the discussion, emphasized the importance of frequent hemoglobin estimations, to determine whether or not the hemorrhage had stopped.

Obstetric, Septic and Anesthetic Toxemias.—Dr. H. G. Wetherill of Denver said that there was a distinct type of postoperative toxemia, caused, among other things, by sepsis, or by late chloroform poisoning. It was quite analagous to the toxemia of pregnancy. Eye symptoms were present, but not so well developed as in the toxemia of pregnancy, because there was not time enough for them to become so marked. Uranalysis showed an acidosis, with a high ammonia coefficient, but no albumin. In many diseases the death picture was so similar that the author wondered whether death was caused, not by the toxins of some disease, but by the accumulation in the system of the products of its own metabolism. The practical lesson to be learned was, not to use chloroform in cases of toxemia with renal or hepatic insufficiency. He thought that the toxemia of pregnancy had many things in common with sepsis, sapremia, and late chloroform poisoning.

Dr. B. Cohen of Buffalo thought that the intestine was the chief cause of the toxemia of pregnancy.

Dr. H. D. Fry of Washington said of the significance of a high ammonia coefficient, that he had been forced to empty the uterus when the coefficient was only 4, and, on the other hand, he had seen patients do well with a coefficient of from 30 to 40. He could not, therefore, agree with the rule of Dr. Williams, of Philadelphia, that the uterus should be emptied when the ammonia coefficient reached 10 per cent.

Dr. Wetherell closed the discussion, saying that he did not believe that Dr. Williams' rule was the last word. Perhaps Dr. Williams might want to modify this rule. He emphasized the importance of an examination of the eyes by a competent oculist.

Diphtheritic Genital Infection.—Dr. Wm. Cuthbertson reported a case of this disease. The woman was delivered in St. Luke's Hospital, Chicago, after several outside physicians had tried and failed. Some days after delivery the temperature rose, and smears from the vagina showed the Klebs-Loeffler bacillus. They could not be demonstrated in the uterus. Ten thousand antitoxin units were administered in divided doses and local treatment employed. Slow recovery took place. Cultures of this organism were fatal to guinea pigs and the organism was obtained in pure culture again from the pigs.

Dr. Keyes of Chicago thought that the acidity of the vagina prevented a woman with faucial diphtheria from contracting a diphtheritic infection of the genital tract.

Dr. A. E. Gallant of New York emphasized the importance of not waiting for the bacteriological report before giving antitoxin. He had found powdered sulphur very effective in killing the bacillus of diphtheria in *situ*.

Dr. Cuthbertson, in closing the discussion, said he would rather give large doses of antitoxin and let the sulphur go, although he supposed that there could be no harm in its local use.

Genital Tuberculosis.—Dr. August Martin of Greifswald, Germany, presented the results of an analysis of his cases. He considered only those in which the tubercle bacillus could be demonstrated in sections. He found that of all serious inflammatory diseases of the pelvic organs coming to operation, 24.6 per cent. were due to tuberculosis. The clinical diagnosis was difficult. In 55 per cent. of his cases there had been menstrual disturbances. Pain and loss of flesh had been variable symptoms. If the Calmette reaction was positive in a pregnant woman with genital tuberculosis, she had enough power of resistance to be able to go on with the pregnancy. If the reaciton was negative, the pregnancy should be terminated. Tuberculous peritonitis was common in young girls and was most often of the exudative type. The diagnosis was relatively easy. The ascites might be diagnosed from that due to carcinoma of the peritoneum by the fact that in tubercular peritonitis the sample aspirated for diagnosis was clear, straw-colored, while in carcinoma it was blood-stained. The treatment was general and local. Ulcers in the vagina were curetted and touched with powerful astringents, as were also ulcers of the endometrium. If the tubes and ovaries were tuberculous, they should be removed, care being taken not to remove any more than was absolutely necessary. Drainage should be used only in mixed infections. The vaginal route should be followed if possible. The after-treatment was important. Guaiacol and creosote had done wonders.

Dr. H. J. Boldt of New York thought that in tuberculosis of the tubes and ovaries two-thirds of the cases could be permanently cured unless the disease had progressed too far in other parts of the body.

Dr. E. E. Montgomery thought that early cases of tuberculous peritonitis were very amenable to treatment.

Dr. H. T. Byford of Chicago thought that tuberculosis should be considered a general rather than a local disease. As such, medicine, not surgery, was the proper treatment for it.

Dr. D. Tod Gilliam of Columbus said that the great majority of cases of genital tuberculosis were descending and he agreed with Dr. Martin that they arose in the gastrointestinal tract. He did not agree with Dr. Byford, however, for he thought that tuberculosis was a local disease from the beginning. Certainly the cure of tuberculous peritonitis by the opening of the abdomen might be credited to surgery.

Dr. C. W. Barrett of Chicago said that from a pathological standpoint we must consider tuberculosis at first a local disease. He thought that it would be a step backward to consider it general.

Dr. Massey protested against curettage, on the general principal that to curette in a microbic infection was to open up new channels for infection.

Dr. Martin closed the discussion by denying that he had done harm to any of his patients by curettage, which he practised only in selected cases and with all possible safeguards against the spread of the infection.

Development of Malignancy in Operation Wounds.—Dr. I. S. Stone of Washington called attention in this paper to certain cases in which carcinoma, sarcoma, and tuberculosis had made rapid strides after operation, and asked whether the spreading of these diseases from cut surfaces could possibly be prevented by antiseptic measures.

Dr. H. J. Boldt of New York said that for years he had had the outer limits of the tissue which he had removed examined microscopically. The report was always negative, and yet recurrences often took place. There must be some predisposition to carcinoma, he thought, in a person suffering from it, for the infection of a surgeon with it from wounds received at operation was an unknown thing.

Dr. H. G. Wetherill of Denver had for five years used a cauterizing clamp, which closed all avenues of infection.

Dr. G. Gellhorn of St. Louis reported a series of thirty-nine cases operated upon in Berlin, with four recurrences, all remote, however, from the site of operation.

Dr. G. B. Massey of Philadelphia counseled care to avoid squeezing tumors during removal, with consequent forcing out of their material upon freshly cut surfaces.

Dr. D. H. Craig of Boston thought that cellular irritation was set up by retractors, etc. For this reason, when he was ready to suture, he always trimmed away with clean, fresh instruments, the edge of the incision.

Dr. Stone closed the discussion by saying that he did not believe that the cautery clamp sealed off more than one-eighth of the cut surface.

Uterus and Stomach: Their Anatomical, Physiological and Pathological Relationships.—Dr. F. J. Taussig of St. Louis thought that a connection between the uterus and stomach by means of the sympathetic system, while probable, was not anatomically demonstrable. Elsner had found acidity of the stomach increased just before the onset of the menstrual flow and diminished during the flow. Thus, it was unnecessary to consider the gastric symptoms which accompanied menstruation as sympathetic. Most cases of hyperemesis gravidarum were not neurotic, but toxic. In retroversion, it was generally a hypoacidity that was present. A few cases with gastric symptoms might be the result of neuroses, but most of them had a definite lesion behind them.

Dr. Carstens of Detroit wished to emphasize the fact that very few of these patients with gastric disturbances were helped by gynecological operations. What they needed was months and months of systematic physical exercise.

Dr. D. H. Craig thought that the more thoroughly patients were examined the fewer would be the neuroses.

Bowel Complications Following Gynecological and Obstetrical Operations.—Dr. C. W. Barrett of Chicago thought that these post-operative complications became fewer as the skill and experience of the operator increased. All unnecessary handling of the intestines was to be avoided, and operations should be completed in as short a time as possible. The causes and treatment of intestinal obstruction were presented in detail. Eserine was recommended for ileus.

Dr. D. H. Craig of Boston thought that meteorism, in the absence of mechanical obstruction, could be avoided after operation by the routine administration of eserine.

Dr. D. Tod Gilliam of Columbus thought that eserine was a valuable drug, but that sometimes dynamic ileus would occur.

Dr. H. P. Jack of Canisteo, N. Y., thought that eserine, given immediately after operation, was invaluable. He said the time consumed by the operator had a very definite effect on the number of cases of bowel complications.

The Expectant Treatment of Ureteral Calculus.—Dr. C. L. Leonard of Philadelphia was of the opinion that the discovery of a calculus in the ureter was not necessarily an indication for its removal. Many calculi would pass by themselves. However, the patient should be most carefully watched, frequent *x*-ray examinations and uranalyses being made. The results of expectant treatment were successful in 60 per cent. of the cases. The discovery of more than one calculus was no contraindication to expectant treatment. The contraindications were, he thought, a large calculus, marked pyuria, rise in temperature and the absence of a bilateral urinary flow. Pus and blood in the urine, in the absence of fever, were not necessarily an indication for operation. Treatment during attacks of colic comprised general anesthesia, if necessary, atropine, and moist heat. Morphine might render slow the descent of the calculus. It was useless to give solvents. The formation of fresh deposits, however, could be prevented by diluting the urine and changing its reaction.

The Injection Treatment of Ureteral and Renal Pelvic Inflammation.—Dr. Edgar Garceau of Boston presented the instrument which he used in this treatment. He used either dilute silver nitrate, or bichloride solution 1-20,000 up to 1-5,000. He had never seen colic result because he had never tried to force the fluid in. Small amounts (10 c.c) should be injected repeatedly. The ureter and pelvis were washed out with boric acid before the antiseptic was applied. The injection should cease as soon as the patient noticed a slight sensation of fullness. Once or twice a week was often enough in most cases. He did not advise the indiscriminate use of this treatment, and these injections should never be used in acute pyelitis. The most suitable cases were those with a considerable pyuria extending over a long period of time. Pyelonephrosis was seldom benefited by this treatment. Chronic ureteritis with thickening was a contraindication to this treatment.

Dr. Young of Baltimore agreed with Dr. Leonard in regard to the expectant treatment of small calculi. He had tried the injection of olive oil above the calculus with success in one case. He showed his dilator for the ureter, similar in principle to the urethral dilator. Local treatment of the renal pelvis he had tried, but it had generally failed. In persistent hematuria the intrapelvic use of adrenalin had been of distinct benefit.

Election of Officers.—At the beginning of the afternoon session the election of the following gentlemen was announced: *Chairman*, Dr. W. P. Manton, of Detroit; *Vice-Chairman*, Dr. H. G. Wetherill, of Denver; *Secretary*, Dr. Jeff Miller, of New Orleans; *Delegate*, Dr. J. H. Carstens, of Detroit; *Alternate*, Dr. Channing W. Barrett, of Chicago.

The Treatment of Fibromyoma Associated with Marked Anemia.—Dr. Benjamin R. Schenck thought that hemorrhage leading to some degree of anemia was

present in from 50 to 60 per cent. of patients with fibroids. But how often the anemia was sufficient to make operation advisable was another matter. There were three important points which one must have in mind in the consideratoin of fibroids—the effect of the anemia, if present, the treatment, and the prognosis. Cardiovascular changes were present, according to Schlegel's series of eighty autopsies, in 40 per cent. of cases with uterine tumors. There were four theories extant to explain the relation between cardiovascular changes and fibroids, no one of which the author considered tenable. In his opinion the anemia was the cause of the cardiovascular phenomena. If this were true, then all fibroids causing increased bleeding at the time of menstruation should be removed. It was the general belief that it was unwise to operate on any patient whose hemoglobin percentage was less than from 40 to 30. Some operators, on the contrary, would not fix any arbitrary point below which it was unsafe to operate. The hemorrhage should be stopped before operation by curettage and packing, or by other means, and the patient built up with tonics. In bad cases he believed ligation of the uterine arteries advisable before the hysterectomy was performed. The operation must be carefully and quickly done. In regard to the prognosis, he thought that grave anemia increased the danger of thrombosis or embolism during convalescence.

Dr. D. H. Craig of Boston reported a case in point, in which the hemoglobin percentage rallied promptly after the operation.

Dr. H. T. Byford had been afraid to operate when the hemoglobin percentage was below 40. When hemorrhage became a symptom, he thought that an operation should be done as soon as the patient could be gotten into condition for it.

Report of a Case of Traumatic Rupture of the Uterus.—Dr. P. H. Swahlen reported a case of rupture of the uterus during labor at full term, with a concomitant rupture of the bladder. Hysterectomy was done, with complete recovery as a result.

Abnormal Secretion from Mammary Glands in Non-pregnant Women.—Dr. George Gellhorn of St. Louis said that a colostrum-like secretion was frequently seen in the breasts of virgins during menstruation. This might even take the place of menstruation and had been known to approach milk very closely in its character. In false pregnancy, colostrum, or even milk, had been secreted. Of five hundred women in their menopause, fourteen had secreting breasts. In 25 per cent. of senile breasts, parenchymatous hypertrophy occurred, which might account for some of the cases of senile secreting breasts. Fourteen cases of mammary secretion in sterile women, all of whom had some gynecological lesion, were noted by one observer. The removal of the ovaries would sometimes start secretion in the breasts of non-pregnant women in the active sexual period. This was not seen if fragments of ovary were left behind. Atrophy of the ovaries had sometimes caused a secretion. A practical knowledge of this subject was necessary to those in medicolegal work.

Dr. Henry of Omaha reported the case of a woman who, after the removal of both tubes and ovaries, had every month a secretion of milk by the breasts, lasting for four or five days. This condition lasted for about a year.

Dr. B. Kohn of New York reported the case of a girl with two supernumerary mammæ which secreted at each menstruation.

Dr. De Lee of Chicago had found it necessary, in the diagnosis of pregnancy, to surround mammary changes with a great many qualifications. He thought that the hypertrophy of the gland tissue and of Montgomery's tubercles was of much more importance than the presence of colostrum.

Dr. Hinchey of St. Louis said that the influence of the ovary on the breast could not account for milk in the male breast, where hermaphrodism could be eliminated.

Dr. Gellhorn closed the discussion, reporting two cases of bleeding from the mammæ in cases of hysteria. These were not cases of vicarious menstruation.

The Menopause.—Dr. Daniel H. Craig of Boston thought that we must combat the idea that diseases which we had treated vainly were going to be cured by the menopause. Symptoms arising during the menopause were due just as much to a definite pathology and needed just as careful treatment as though they had arisen at any other time. The vasomotor disturbances were probably due to changes in the anatomy of the ovary. Erratic menstruation, if carcinoma of the cervix could be excluded, pointed to trouble in the body of the uterus. Pain, generally inguinal, and leucorrhea were almost always signs of cervical disease requiring attention. Practitioners, then, should teach women that the menopause is a physiological period and that symptoms arising during its course should be treated.

Ablatio Placentæ.—Dr. R. W. Holmes defined this as the premature detachment of the normally situated placenta. It was more common than was generally supposed, but was almost always mistaken for placenta prævia. It was probably about one-half as frequent as placenta prævia. The direct cause was violence, the indirect cause multiparity, it being more common in women who had borne children and who were in the second or third decade of the child-bearing period; and the pathological causes were inflammatory changes in the endometrium, nephritis, placentitis, and lesions in the blood-vessels of the uterus. Hemorrhage was the sole pathognomonic symptom. The amount of jeopardy to mother and child should never be judged by the amount of blood appearing in the vagina, for every case had a greater amount of blood remaining behind in the uterus. Serum escaping from the vagina was not to be mistaken for liquor amnii. An accessory tumor was found in about 50 per cent. of the cases. Pain was nearly always present, with nausea, or even loss of consciousness. The treatment should be immediate delivery. The cervix was generally soft and readily dilatable. Manual dilatation was best in these cases. Vaginal cesarean section would be the ideal method of delivery if the field were not so entirely obscured by blood. Abdominal section, in cases with rigid cervices, was good in hospital cases. After labor the uterus and vagina were to be packed with gauze. This hemorrhage was the only one admitting of the use of ergot before the delivery of the placenta. It should be given in small doses.

Dr. De Lee was not entirely satisfied with the term "ablatio." He had suggested and used "abruptio." He had seen an accessory tumor only once.

Dr. S. Strauss of New York thought vaginal cesarean section the method of treatment *par excellence*.

Dr. McKowan of Memphis reported two cases that had occurred in his practice recently.

Dr. Harter of Stronghurst, Ill., and Dr. F. T. Marshall of Chicago each reported a case.

Dr. Holmes closed the discussion, saying that he used the term "ablatio" because he thought that it covered the case better than any other.

Prolapse of the Rectum and Sigmoid Flexure Following Hysterectomy.—Dr. L. T. Hirschman of Detroit reported two cases and described an operation which he had devised for their cure. The sigmoid was pulled up and a fold sewed in its mesentery.

Dr. D. Tod Gilliam of Columbus asked whether the sutures were introduced at right angles or parallel to the vessels of the mesentery. If at right angles, had the circulation been interfered with?

Dr. Hirschmann replied that the sutures had been inserted at right angles to the blood vessels, but that care had been taken not to include the vessels in the sutures.

The Adjustable Canvas Chair as an Aid in the Murphy Treatment of Diffuse Suppurative Peritonitis.—Dr. D. Tod Gilliam described a chair which he had devised, the object of which was to prevent the patient from becoming soiled by his evacuations and to make his position more comfortable. It was like an ordinary steamer chair, in which the canvas had been replaced by rubber. Any position between the upright and the nearly horizontal could be assumed. There was an oblong opening in the rubber, which allowed the excreta to flow away into a vessel. It combined cleanliness, convenience, cheapness and comfort.

Serum Treatment of Carcinoma.—Dr. S. Strauss of New York believed there was some cause at work in the production of carcinoma other than local irritation. His method of treatment was the injection of the serum of an animal (generally the horse), who had a tumor similar to that of the patient. There was generally some reaction after the first or second injection—flushed face, rise in temperature, and restlessness. The dose varied from one-half to fifteen cubic centimeters. He reported the treatment of thirty cases with this serum. The symptoms had been ameliorated, and one case, a recurrent carcinoma of the pylorus, had apparently been cured.

Dr. J. J. Watkins of Chicago thought that the results were encouraging.

Dr. Strauss said he did not wish to be understood as claiming to cure cancer. It was only that he was working on a treatment, the results of which so far had been encouraging. The cure which he reported might have been only a coincidence.

Thursday, June 4—Third Day.

The Corset for Movable Kidney and Associated Visceral Ptoses.—Dr. A. E. Gallant, the reader of this paper, was of the opinion that 99 per cent. of cases of movable kidney could be relieved by properly constructed corsets. The corsets must fulfil two conditions, namely, they shall restore the displaced viscera to their proper positions, and keep them there. The ordinary corset, laced tightly at the waist, would relieve the symptoms of a movable kidney, but the dyspepsia, constipation, etc., associated with the enteroptosis so frequently coexisting, would be increased. The corset which the author recommended must, he said, be made to order from accurate measurements, and must conform to the latest mode—else fashionable women would not wear it. The front steels must overlap the upper part of the symphysis pubis. The corset should be put on while the patient was in a recumbent posture, with the hips elevated, and the legs exactly at right angles to the bed. The abdomen should be massaged upward, and the corset then put on, and fastened in front from the bottom upward. It was then laced up behind. The only difference between this corset and the type ordinarily in use was that the front was enlarged from below upward, V-fashion, to make room for the stomach that had been replaced. The corset pressed the sides in at the waist, and allowed more room in front, so that the waist was not enlarged. A cross section of the waist would thus be almost a circle, instead of, as was the case with the ordinary corset, an oval, with the short diameter in the sagittal plane.

Dr. DeLand of Philadelphia thought that the ordinary corset increased the gastroptosis, and wished to ask whether the *x*-ray would demonstrate the stomach and colon in their proper positions. She had never yet found a corset that would do this, and had had to rely on bandages.

Dr. McLane of St. Louis had tried the Gallant method and had found it of great value, especially after abdominal section with drainage, where this corset was more comfortable than a binder.

Dr. Gallant closed the discussion, showing by means of diagrams why the binder failed in its purpose.

The Suture: Its Place in Surgery.—Dr. Henry O. Marcy thought that the interrupted suture was time-consuming and had no advantages over the continuous suture. In suturing, like structures should be coapted—muscle to muscle, fascia to fascia. Fine running sutures carried out this rule. The over-and-over suture (glover's stitch) was not nearly so good as the parallel suture, with which latter coaptation was more evenly secured, and the suture buried in firm, healthy tissue. The needle he thought as important as the suture. It was best to use a curved Hagedorn needle of medium size so that it could be grasped with the fingers if necessary. All aseptic incisions, closed with buried aseptic sutures of kangaroo tendon, would remain aseptic; and if the work were well done the scar would be almost invisible. In two thousand laparotomies he had had but one hernia. The buried animal suture the reader thought had been his best contribution to surgery, and recommended that the animal material be kangaroo tendon.

Dr. H. P. Jack of Canisteo, N. Y., had never used anything but catgut. He reported a case of aseptic breaking down of a laparotomy wound which had been closed in layers with No. 2 thirty-day chromic gut. Pulse and temperature were normal for two weeks, at the end of which period the wound opened and the intestines escaped. The woman was of a very gouty constitution, and he thought that this might have had something to do with the rapid absorption of the gut.

Dr. D. Tod Gilliam of Columbus had had such evil results with catgut that he had returned to silkworm gut.

Dr. A. E. Gallant of New York had found that double knots were a frequent cause of the accumulation of serum in a sutured wound. The gut was absorbed but the knot remained as an irritant.

Dr. Marcy closed the discussion. In reply to Dr. Jack he said he, too, was of the opinion that the fault lay with the reparative processes rather than with the catgut. In long abdominal incisions he liked to keep the abdominal wall at rest with strips of adhesive plaster.

The Advisability of Prompt Evacuation of the Uterus in Eclampsia.—Dr. Henry D. Fry of Washington said that of all the theories of the etiology of eclampsia that of autointoxication was the most promising. Lesions were found in the liver, kidney and brain, and the outcome of the disease corresponded to the degree to which these lesions had advanced. As a rule they had not advanced beyond the danger line before the first convulsion. He thought the obstetric treatment was infinitely more important than the medical treatment, and that one should take no chances by trying to eliminate a poison while its elaboration was still going on. The uterus should be emptied as soon as possible and only then should efforts be made to get rid of the toxin already absorbed. By this method the mortality would be reduced to its lowest figure. By this treatment fifteen cases of eclampsia and one case of preeclamptic toxemia showed a maternal mortality of one. Twelve of these cases had had no convulsions after delivery, two had had two convulsions, and two had had one. The fatal case was practically moribund at the time of operation. The methods used had been vaginal cesarean section in twelve cases, manual dilatation and forceps in two cases, manual dilatation, incisions of the cervix and forceps in one case, and symphysiotomy and forceps in one case. The writer admitted that the infant mortality was high, but thought it was not any higher than under the expectant method of treatment.

Dr. Laura Branson of Iowa City thought that a great deal of the toxemia was due to the fetus and that this indicated early delivery.

Dr. Sprig of Washington said that in preeclamptic toxemia near term, he had been accustomed to empty the uterus without waiting for a convulsion. He had never felt that a uterus had been emptied too soon, but had often felt that one had been emptied too late.

Dr. H. J. Boldt of New York thought the important question was, How shall we deliver these cases most quick-

ly and safely? In postpartum eclampsia he felt that decapsulation of the kidney should not be dismissed without thought.

Dr. Harris of Chicago emphasized the importance of early evacuation of the uterus.

Dr. B. Kohn of New York thought that women should be educated to place themselves under medical care early in the pregnancy.

Dr. Carstens of Detroit agreed with the previous speaker in regard to the early consultation of women with their physician. There was only one way, he thought, to empty the uterus rapidly. That way was vaginal cesarean section. This operation should be learned by the general practitioner, for it was he who saw these cases first. Thus much valuable time would be saved.

Dr. August Martin of Greifswald, Germany, said that veratrine, morphine, and chloroform would have to be given up as soon as we agreed that eclampsia was a toxemia. He thought it most likely that the toxemia was produced by the ovum, and agreed entirely with the previous speakers who had insisted on the early evacuation of the uterus. Decapsulation of the kidney, he thought, might possibly be tried in appropriate cases, but he did not dare to recommend it. Certain it was that prophylaxis was the most important phase of this whole question. Could we not diagnose the coming danger? He believed that we could, for these were prodromal symptoms of great importance. Some of these were severe headache, loss of appetite, a feeling of lassitude and sleeplessness. The quanity of urine was diminished, and cells showing fatty degeneration were found, and sometimes albumin. Edema of the limbs which does not disappear after rest in bed, as does that caused by the weight of the pregnant uterus, was another important danger signal. Finally the arterial tension increased rapidly and remarkably. Thus, he thought, the development of the toxemia could be recognized long before the appearance of the convulsions. The treatment was to increase the action of the skin by measures other than the administration of drugs. If the condition did not improve, the patient should then be sent to a hospital or sanatorium, where she could be most closely watched. If then the symptoms persisted, the pregnancy should be interfered with. The bougie and the bag required too much time, and he advocated most strongly vaginal cesarean section.

Dr. Chas. Jewett of Brooklyn was substantially in accord with the theory that the toxemia was due to the presence of the child in the uterus, but thought that it was frequently of hepatic origin, and occasionally, was primary in the kidneys. He agreed that evacuation of the uterus was the only treatment.

Dr. Warthen of Louisville thought that eclampsia should be prevented, and that it could be prevented with proper care. He thought eclampsia was the result of an enzyme, originating in the epithelial structure of the chorion by some method that we did not at present understand.

Dr. Fry closed the discussion, saying that it had been his idea to present a paper on a single topic—the advisability of emptying the uterus in eclampsia. He could not believe, with Dr. Carstens, that the general practitioner could do a vaginal cesarean section. Decapsulation, since attention had been diverted from the kidney as the primary cause of eclampsia, had fallen into disrepute. It might, however, come into play in postpartum cases.

The Conservative Surgeon and the Symptomless Uterine Fibroid.—Dr. Thos. B. Eastman of Indianapolis said that a fibromyoma might frequently be in such a condition as to endanger life without this fact being discovered until it was seen at operation, or upon microscopical examination. While it was not possible for a fibroma to degenerate into a carcinoma, still there seemed to be some relation between the two, for cancer of the body of the uterus was eight times more frequent in the presence of fibroids. Necrosis was the most frequent degeneration with which we had to deal, and this, or even carcinoma or sarcoma, might exist without symptoms. Symptomless cystic ovaries, chronically inflamed appendices and gallstones were all removed by the conservative surgeon; why not a symptomless fibroma, when it had been shown that twelve per cent. of fibromata, if allowed to remain, will ultimately show conditions which would threaten life. The idea that fibromata shrink up after the menopause was fallacious, and we know that 64.9 per cent. of the dangerous degenerations occurred after the fortieth year. The idea that the menopause was a natural cure for fibromata was, then, a relic of the dark ages of surgery. He therefore strongly advocated the removal of fibromata before they had a chance to degenerate.

Dr. Andrews of Chicago said that he was opposed to this idea.

Dr. H. J. Boldt of New York said that sarcomata which were supposed to have been the result of degenerated fibromata had probably been sarcomata from the beginning, and not a malignant degeneration of a preexisting fibroma. He believed that the uterus should be removed with a fibroma that was causing symptoms, but was opposed to the removal of the uterus with a symptomless fibroid. He had seen fibromata in patients who had refused operation, retrograde and become smaller.

Dr. Lawrence of Columbus said that the danger from the operation itself was practically *nil,* while the danger of malignancy was 5 per cent. and of necrosis and suppuration also 5 per cent., or even greater, especially where tampons and electricity were used as treatment. Besides these dangers, there were the results of pressure. He therefore agreed that fibromata should all be removed.

Dr. Carstens of Detroit thought that a woman really suffered in the idea that she was the victim of a tumor which might some day cause trouble. He thought that this in itself was a sufficient indication for the early removal of fibromata.

The Non-Surgical Treatment of Uterine Displacements.—Dr. H. J. Boldt said that the practice of minor gynecology had been almost lost sight of in the past few years, because of the advance that has been made in gynecological surgery. It was true that surgery would cure displacements of the uterus far more rapidly and surely than they could be cured by non-surgical means, but there were patients upon whom, for one reason or another, operation was unadvisable, who could be relieved by properly adjusted mechanical support. The displacements that were most frequently amenable to mechanical treatment were posterior displacements, and descensus of the uterus, with or without descensus of the vagina. The posterior displacements the reader divided into retroposition, retroversion, and retroflexion. Retroposition he thought was not likely to cause symptoms. Retroversions were sooner or later accompanied by retroflexions. The majority of retroversions and retroflexions were acquired, and in this type of cases, rather than the congenital cases, which were more apt to be benefited by mechanical treatment. It was the acquired malpositions, too, which were more apt to give rise to symptoms. Retrodisplacements fixed by inflammatory adhesions were not suitable for treatment by pessaries, nor should the pessary be used in the presence of any acute inflammatory condition in the pelvis. In using a pessary the uterus should be replaced bi-manually before the pessary is introduced. If this was impossible, the condition was not suitable to the proposed treatment. In replacing the pregnant retroflexed uterus, the author said that he was in the habit of reducing the displacement while the woman was in the knee-chest position, and then introducing the pessary. The retroflexions most amenable to permanent cure were those of recent postpartum origin. A patient should not be conscious of a pessary and would not be, if the pessary were of the proper size

and shape, and in correct position. The most suitable pessaries were the Albert Smith and the Thomas. A cure, when cure was possible, required from two to five years. From twenty to twenty-five per cent of uncomplicated, mobile, backward displacements of the uterus could be permanently cured by this means. Occasionally it was proper to forcibly break down light adhesions under anesthesia in order to get the uterus into proper position for the application of the pessary. In doing this, it was necessary first to rule out tubal complications. The pessary treatment for acquired pathological anteversions and anteflexions the reader considered practically useless except to relieve the vesical tenesmus. Only one kind of pessary was of any use in this type of case—the Gehrung. The treatment by pessary of congenital anteflexions was useless.

Dr. Hall of Kansas City thought the pessary should never be used in the presence of adhesions, or of pathological conditions in the adnexa. It was often impossible to say whether the uterus was in its proper position or not, before the pessary was applied. He considered it necessary that some sort of guide be passed into the uterus to make the solution of this question easy. The best cure for retrodisplacements, outside of surgery, he considered to be pregnancy—the uterus being allowed afterward to involute in its proper position.

Dr. G. Gellhorn of St. Louis deplored the frequent operative treatment of malpositions of the uterus. He thought that in using the intrauterine guide advised by the last speaker there was always the danger of perforation. He did not believe that the pessary would ever cure retroflexion of long standing.

Dr. A. Goldspohn of Chicago agreed with the essayist in all that he had said, except in the question of cure. He did not believe that permanent cure took place, except in malpositions after labor, where the element of involution was still present.

Dr. Bertha VanHusan of Chicago had treated many cases of prolapse of the uterus with glass globe pessaries with a great deal of success. There must, however, be some muscular perineum left.

SECTION ON ANATOMY AND SURGERY.

Friday, June 5—Fourth Day.

My Present Position on Appendix Questions.—Dr. Robert T. Morris of New York read this paper. He now ligated the stump and carbolized it. He restricted the size of the abdominal incision and tried to do the work in as short a time as possible. He had given up flushing and the use of the gauze wick drain. He said we were now at the dawn of the physiological era of surgery.

Dr. A. J. Ochsner of Chicago said that his attitude toward operation for appendicitis had come to be about as follows: As to the need of immediate operation in nonpurulent cases, sufficient observation had been made to make it safe to say that there should be no question or hesitation. The elimination of the purulent appendix from the general peritoneal cavity till it could be safely operated upon was a life-saving plan, and it should be practised in those cases where immediate operation might be fatal. Certainly this dictum applied to the surgeon of average skill, if not to all, and, properly applied, it had reduced the mortality from 16 per cent. to 2 per cent.

Dr. J. B. Murphy of Chicago spoke of the need of the greatest speed combined with the least traumatism to the tissues. Simple ligation of the stump he practised under certain adverse conditions, but in the ordinary interval operation he would not consider it justifiable—in any event there ought to be a smooth cuff of peritoneal covering placed over the raw surface to prevent adhesions. As to peritonitis in pregnancy, he said the mortality was so surprisingly high that he always advised appendectomy before the end of the second month. In forty-three cases of general peritonitis from perforating appendicitis, he had had forty-one recoveries. The treatment in each case consisted simply in posture, drop method of rectal irrigation, drainage, no flushing, no trauma, no wiping.

Dr. Alexander Ferguson of Chicago said it was difficult to know just what was meant by a "small incision." There was in all these things a large element of personal equation. For example, some of the cases whose bellies and rectums Ochsner washed out seemed to him to need a very small incision to establish a point of least resistance for escape of gas.

Dr. Graham of Rochester, Minn., said that in the absence of both the Mayos he would say that it was customary with them to proceed as follows: Operate at once if within 48 hours of onset of attack. If after 48 hours, in chosen cases the starvation treatment of Ochsner was employed. If abscess had already formed, it was drained through a stab. Then, after all had healed, the appendix was taken out. No search was ever made for it at time of primary operation.

Dr. Eisendrath of Chicago said the dictum was that cases of general peritonitis should be left alone—there was no use of operating when too late, when the general resistance and the index were so low that all was hopeless. Operation in these cases gave just the added shock to carry such patients over the lethal line. All such patients should be put in Fowler's position and be starved until they were tided over. At the Michael Reese Hospital, of the last 34 cases of general diffuse peritonitis, 21 had been saved by this course. Of his own last 12 cases, he had been so fortunate as to save 11 out of 12, but this he feared was coincidence. He thought that a combination of the Ochsner method with Murphy's drop irrigation—for which latter he was perfecting a simple device—seemed to give the best grounds for hope. He thought it certain that many of these patients died of acute dilatation of the stomach. All patients should have advantage of the Fowler operation.

Vesical and Renal Calculi and Vesical Tumors.—Dr. Carl Beck of New York read this paper. He gave many valuable statistics and made the following deductions: Most vesical calculi are originally formed in the kidneys which explains the frequent recurrence of vesical calculus after operation. Therefore a roentgenograph of the renal regions must be taken whenever vesical calculus is found. The cystoscope diagnosticates vesical tumor when skiagraphy may recognize a calculus, this phenomenon being explained by the fact that the tumor is interspersed with calculous elements. This shows the necessity of always combining cystoscopy with skiagraphy.

Dr. Rodman of Philadelphia said that in 1901 he saw some of Ochsner's work. So convinced was he of the soundness of his teaching that he determined to put it into immediate practice. It had done more to straighten out the problem of when to operate than any other single contribution. It was not a substitute for operation. Personally he did not invert the stump, but ligated it, covering carefully with mesoappendix.

Dr. Rogers of Chicago said that often pain was due to the catching of nerves in fibers of connective tissue bands. Leucocytosis was of little value save as an indication of the resisting ability of the patient—the important consideration was the differential count.

Dr. Rolly of North Carolina said that Ochsner's treatment had generally been sorely misunderstood. By some this had been intentional, for it sometimes served as a convenient device of physicians to keep the patient out of the surgeon's hands and allow a so-called "cure by nature." Others honestly thought the Ochsner treatment was actually a substitute for operation rather than the handmaiden of it. Misinterpretation from whatever cause had led to the unnecessary death of thousands of patients who might have been saved by timely operation. The

object of the treatment, its uses as well as its abuses, should be thoroughly understood by all concerned.

Dr. Morris, in closing, said that the Ochsner treatment had not given good results in the hands of New York surgeons. Simple ligation of the stump he regarded as a safe procedure.

Dr. Ochsner in response to calls from the audience replied that he had feared the very outcome to which speakers had referred and had used the method for eight years before publishing it. Since then he had spared no pains to make the indications as clear as day. They had been published frequently and in great detail. He insisted that it had always been advised for inoperable cases only—cases in which death would certainly take place under immediate operation. It reduced the mortality from 16 to 2 per cent. In time drop irrigation of the rectum and Fowler's position might be added to the Ochsner treatment. Pus certainly could be absorbed from the abdominal cavity if present in not too great amount.

Dr. Murphy of Chicago said there was pus and pus—there were very destructive types of pus. Tension was the chief element of danger. He advocated the drop method of saline irrigation of the rectum after all serious operations, whether abdominal or not.

Invagination of Limited Annular Gangrene of the Small Bowel vs. Resection.—Dr. J. E. Summers of Omaha read this paper. He said that annular gangrene of the small intestine one-half to one centimeter wide was not infrequently met with. Stricture might follow repair of gunshot wounds if ordinary invagination was practised. Resection of such wounded gut had in the past been practised, sometimes with artificial anus formation. The essayist had shown by several cases that severely injured gut from whatever cause could be successfully and quickly treated by artificial intussusception, the position being maintained by suture. Devitalized bowel sloughed and lumen was restored.

A New and Rapid Method of Perineal Drainage in Suprapubic Cystotomy.—Dr. Joseph Ransohoff of Cincinnati read this paper. He said that in the suprapubic operation hemorrhage was easily controlled by the free use of formaldehyde-gelatin. It was true that the suprapubic operation had the higher death rate, but this was in part due to the fact that first, it was reserved for the most difficult cases and, second, that it had in the past suffered from inability to be followed by perfect drainage. Drainage from buttonhole or by self-retaining catheter in the urethra had always been unsatisfactory. He showed a trocar and cannula which having a proper curve he had experienced no difficulty in pushing down past the rectum and, on his index finger as a guide, out through the skin of perineum. A tube was easily passed through this and it gave good drainage.

Dr. H. Young of Baltimore said that different varieties of germs determined the reaction of the urine. This was particularly true of proteus. The *x*-ray had been of use in renal and ureteral stones, but of no value in diagnosing vesical calculi. The cystoscope was a necessary adjuvant to the diagnosis of ureteral calculi, for seminal vesiculitis with all the symptoms of renal stone had to be differentiated from it. Time was not the element in mortality, for the suprapubic and perineal work could be done in equal time. He had done many prostatectomies by the suprapubic path. The overwhelming hemorrhage was the chief danger factor of the upper route. By the lower, no packing was necessary; in 200 cases at the Johns Hopkins Hospital there had been no injury to the rectum. He thought that owing to the frequent existence of the rectal pouch the trocar might cause great damage.

Dr. Ransohoff said that this objection to the trocar was purely theoretical.

A Study of Anterior Poliomyelitis, with an Analysis of 647 Cases, from the Children's Hospital, Boston.—Dr. R. W. Lovett of Boston read this paper. He said a very important anatomical point bearing on this disease was that the cells were grouped in bundles running the length of the cord, while the blood supply came in at right angles. Hence a poison which gained entrance through the blood might destroy some motor cells and leave others intact. He referred to statistics—effect of sex and age and climate and to treatment.

Dr. E. H. Ochsner of Chicago said that the first thing to do for these cases was to give a good dose of purgative to get rid of all possible germs in the alimentary canal. There were two points in particular to which attention should be directed, viz.—the reestablishment of muscle equilibrium at the end of operation—it was not strength so much as equilibrium which was the determining factor—learning coordination of movement one point at a time was the second important factor.

Dr. Lovett in closing said that tendon grafting alone followed by prolonged plaster rest was a very poor practice. The after treatment was the most important consideration.

A Function of the Lesser Trochanter.—Dr. V. P. Blair of St. Louis read this paper. He showed a series of remarkable anatomical preparations of the region of the lesser trochanter which showed that (1) the lesser trochanter carried the insertion of the psoas tendon mesialward to a point just outside the axis of rotation, and (2) that the muscle caused to a slight degree internal rotation of the femur.

Preservation of Anatomical Dissections, with Permanent Color of Muscles, Vessels, and Organs, by a New Method.—Dr. Edmond Souchon of New Orleans read this paper. He said the embalming solution was important. It should be composed of arsenic, carbolic acid, formalin, and glycerin, the proportions being the keystone of success. Arteries should be injected with tallow and vermilion, and veins with tallow and ultramarine blue. This takes one to ten days before dissecting. The part should be allowed to drain to get rid of superfluous water. After dissection it is immersed in 1 per cent. solution of carbolic acid until it ceases to color the water; the latter should be changed whenever bloody. The dissection was then to be placed in an empty glass jar and covered. This curing stage should last from four to six weeks. The arteries and veins should next be painted with moist colors, which must be dried thoroughly. The specimen was then placed permanently in a weak solution of alcohol, 20 ounces to the gallon. Specimens which did not develop satisfactorily, which did not stain, or which paled in alcohol, should be placed in a weak solution of carbolic acid until they developed a satisfactory color. They should be removed if the tendons or other white tissues presented a tinge of red gold and should be put permanently in a weak alcoholic solution.

Mucomembranous Enterocolitis. — Nepper defines mucomembranous enterocolitis as a slow, symptom complex characterized by constipation, pain, and formation and coagulation of an abnormal amount of mucous in the colon. The hypersecretion of mucus depends on an excitation of the great sympathetic. Normally, the mucus is reabsorbed in the digestive tract. In enterocolitis this resorption does not take place. Coagulation depends upon the coagulating power of an intestinal product called mucinase. Bile retards this coagulation. In mucomembranous enterocolitis there is a failure of the liver function which permits of coagulation. Intoxications, inflammations, and psychical influences all diminish the secretion of bile by inhibitory influences on the sympathetic system. Biliary secretion being lessened, and peristalsis disturbed, mucinase acts and the syndrome is established.—*Gazette des Hôpitaux.*

Books Received.

The MEDICAL RECORD *is pleased to receive all new publications which may be sent to it, and an acknowledgment will promptly be made of their receipt under this heading, but it must be with the distinct understanding that it is under no obligation to notice or review any publication received by it which in the judgment of its editor will not be of interest to its readers.*

Contagious Diseases, Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ending June 20, 1908:

	Cases	Deaths
Tuberculosis Pulmonalis	428	143
Diphtheria	377	30
Measles	841	21
Scarlet Fever	410	25
Smallpox	1	—
Varicella	108	—
Typhoid Fever	38	9
Whooping Cough	48	3
Cerebrospinal Meningitis	7	7
Malarial Fever	—	—
Totals	2,258	238

Health Report.—The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, for the week ending June 19, 1908:

SMALLPOX—UNITED STATES.

		Cases.	Deaths.
Alabama, Mobile	May 23–30	1	..
California, Los Angeles	May 23–30	1	..
San Francisco	May 23–30	15	..

INDEX.

A.

Abbott, E. G., report of thirty-one cases of congenital dislocation of hip joint reduced by manipulation, 848.
Abdomen, constructive surgery after gunshot wound of, 633.
Abdominal cavity, three procedures for entering the, 1015; incision, the, 286; section, after-treatment of, 1091; surgery, postoperative complications in, 75.
Abortion, and labor, febrile conditions in, 167, 364; criminal in its broadest sense, 1013; specimen of tubal, 753.
Abrams, Albert, autointoxication and indicanuria, 689; the physical signs of incipient pulmonary tuberculosis, 309.
Abscesses, method of obtaining rapid healing of acute, 957; of skin in nursling from colon bacilli, 872; treatment of ischiorectal, 212.
Accidents, and functional nervous diseases, 54; on street railways, 694.
Acetate of aluminum or acetate of ammonium, 193.
Acetonuria and laparotomy, 239.
Achilles tendon reflex, significance of, 957.
Acid intoxication, pathology of, 664.
Acidosis, histological evidence of, 905.
Actinomycosis of the lung and liver, successfully treated with a vaccine, 535; six years after operation, 161.
Adenocarcinoma of uterus, 669, 753.
Adenoids and open windows, 272; and tonsils, 277; curette, a new, 884; in adults, 1088; observations on the removal of, 364.
Adiposis dolorosa, 618.
Adrenalin, effect of prolonged medication with, 708; in spinal anesthesia, 32.
Adrenals, changes in, in arteriosclerosis, 904.
Advertising specialists, prosecution of, 779.
Age, chronological and anatomical, 1051; of effective work, 903.
Air, bad and good, and the uses of the latter, 586.
Air-borne infections, their mode of entrance: preventive, abortive, and ameliorative treatment, 316.
Air-tract, relations of the jaws and teeth to the upper, 241.
Albumin, estimation of, by electrical conductivity, 652; sera for plant, 495; the minimum requisite, 32.
Albuminuria, orthostatic, 188.
Alcohol, effect of, on the secretions, 246.
Alcoholic stupor, postdelirious, 240.
Alcoholism, chronic, 662; complications of, 323; to further the scientific study of, 490.
Alimentary intoxication, 663.
Allen, Alfred R., the term "stauungshyperæmie," 19.
Alopecia areata, formaldehyde, 280.
Alpha Omega Alpha Medical Scholarship Society, 907.
Altruism, sowing the seed of, 608.
Ambulance, green cross, 947; park, to be discontinued, 23; surgeon resisted, 233.
American Association of Medical Milk Commissions, 907.
American Gastroenterological Association, 995.
American Gynecological Society, 995.
"American Health," 862
American Hospital Association, 947.
American Medical Association, election of officers, 1005.
American Medical Editors' Association, 995.
American Medico-Psychological Association, 779.
American Orthopedic Association, officers of the, 1082.
American Pediatric Society, 655.
American Sanatorium Association, 24.
American Surgical Association, 824.
Amputation of the forearm *in utero*, 360.
Analgesics in pediatric practice, 503.
Andrews, resignation of Mr. C. S., 23.
Anemia, of infancy, 1052; pernicious, 750; separation processes in, 1079; some aspects of splenic, 618.
Anesthesia, accidents during, 784; by various methods, 278; clinical study of, 871; commission, report of the, 1010; fatalities in Iowa, 286; general, 750; legal responsibility in cases of death during, 819; prevention of complications after, 22; prevention of death during, 99; status lymphaticus in relation to, 280; study of 600 cases of, 1087.
Anesthesias, eighty lumbar, without failure, 324.
Anesthetics and status lymphaticus, 71; deaths under, 619; question of, 859.
Aneurysm, cardiac, 966; phenomenal aortic, 636; pneumococcic suppuration in femoral, 448; statistics of the Matas operation for, 488; surgical treatment by intrasaccular method, 968.
Angioneurotic pseudoperiostitis, 609.
Ankylostoma duodenale, the hemolytic action of, 535.
Ankylostomoanemia in children, 43.
Anthrax, the treatment of, 65; two cases of, 494.
Antimony, a plea for, 495.
Anti-Noise Society, children's hospital branch of the, 193.
Antitoxin and albumin, 114.
Antivaccination, 994.
Antivivisection bill, the, 153, 694; bill introduced, 233; in Europe, 441.
Antivivisectionists, mass meeting of the, 316.
Aortitis, acute syphilitic, 990.
Aphasia, 1046.
Appendical infections, 789.
Appendicitis and diseases of the female pelvis, 288; causes of, 155; classification of, 169; diagnosis of, 241, 409; diagnosis of the location of the appendix in, 313; early operation for, 409; in the nursing child, 252; lymphatic and portal infections following, 221; masked, 497; operation on ocean liner, 23; pyelitis from, 785; relation of, to gynecological diseases, 595; renal and ureteral calculi complicating or simulating, 427; surgical treatment of, 701; traumatic, 525; treatment of, 1097; unilateral elevations of temperature in, 665; wave, 779.
Appendicostomy, five cases of, 580.
Appendix and gall-bladder, diagnostic prevention of the terminal stages of infections of the, 213; diverticulum of the, 29; harmful involution of the, 123; inverted, 754; metaplasia of the, and a new diagnostic point, 541; parasites in the, 190; primary cancer of the, 501; the, in a femoral hernia, 288; treatment of stump, 789.
Archives of Diagnosis, 317.
Archives of Internal Medicine, 402.
Arizona Medical Association, 824.
Arkansas State Medical Society, 948.
Army, a new ration for the, 611; canteen association, 654; medical department examinations, 993; medical department, increase of, 859; officers, endurance tests, 862; physical training in the, 820; riding tests, 737.
Arsenic in the early stages of syphilis, 398.
Arterial disease, experimental, 708; tension, high, of nervous origin, 1011.
Arteriosclerosis, 196; changes in adrenals in, 904; local, 494; pulmonary, 839; radial, 524.
Artery, innominate, successful ligation of, 968.
Arthritis deformans of hip, 878; strain as a factor in infectious, 69.
Arthrodesis and tendon transplantation, 664.
Asepsis, the use of chemicals in, 367.
Ash, anthracite coal, as a surgical dressing, 534; free diet and salt metabolism, experiments on, 1053.
Aspirator, a new, 861.
Association of American Medical Colleges, 441.
Association of American Teachers of Diseases of Children, 695.
Asylum, plea for custodial, 795; site for the new custodial, 571.
Atheroma and ovariotomy, 736.

Athletic contests, the effect of, on the health, 271.
Autointoxication and indicanuria, 689; operative treatment of, 186.

B

Babies, summer camp for sick, 1050; to be cared for, 994.
Bacteria in running streams, 777.
Bacterial disease, vaccine therapy in, 111.
Bandler, Samuel W., the relation of appendicitis to gynecological pelvic diseases, 595.
Bangs, L. Bolton, some observations on the effects of tobacco in surgical practice, 421.
Barberio's sperm reaction, 916.
Barrett, Channing W., intramural transplantation of the round ligaments versus Alexander's operation or ventro-suspensio-fixation of the uterus for retroversio-flexion, 686.
Barshinger, M. L., sciatica, 683.
Bartlett, W. A., blood reactions of inflammation and the diagnostic prevention of the terminal stages of infections of the appendix and gall-bladder, 213.
Baruch, Simon, instruction in hydrotherapy, 92; Dr., at Winternitz's clinic, 947.
Basle nomenclature, criticism of, 862.
Battle, Ivan P., amputation of the forearm *in utero*, 360.
Beaumont, J. C. H., chlorine as a germicide, 359.
Beck, Carl, a new bone drill and bone wrench, 43.
Bed sores, 333.
Berg, H. W., differential diagnosis of meningococcus cerebrospinal meningitis from other types of cerebrospinal meningitis, 887; poliomyelitis anterior as an epidemic disease, 1.
Beriberi, 914.
Berlin, letters from, 277, 362, 530, 911, 952.
Bier's congestion, experimental observations on, 410; hyperemic treatment, 876, 1006.
Bile, changes in the, in infectious diseases, 37.
Bill, an unnecessary, 103.
Bishop, Louis Faugères, several cases illustrating liver symptoms in cardiac disease, 1069.

Drainage, abdominal, with aspiration, 582.
Druggist convicted, 190.
Drugs, aural effects of common, 831.
Dublin, pasteurized milk in, 1036.
Duchenne of Boulogne, 50.
Dukeman, William H., a case of ectopic gestation, 146.
Dunham, Henry B., incipiency in tuberculosis, from the standpoint of sanatoria, 220.
Duncan, C. H., the art of surgical knot tying, 937.
Duodenal ulcer, perforated, 160.
Duodenum, obstruction of, by root of mesentery, 748; ulcer of the, 283, 1007.
Düsseldorf post-graduate medical school, 488.
Dutton, W. F., blood pressure in the practice of medicine, 599.
Dysentery, appendicostomy in, 112; due to ciliates, 31; surgical treatment of, 367.
Dysmenorrhea, Roentgen ray treatment in, 610; treatment of, 315.
Dyspepsia, chronic, 155; treatment of functional, 750.

E.

Ear and nose diseases, intracranial complications of, 1006; gastrointestinal symptoms in suppuration of the middle, 446; intracranial complications of suppuration of the middle, 248; suppurations of the middle, in infancy and childhood, 350.
Eccles, R. G., Darwinism and diabetes, 757.
Eclampsia, blood pressure in, 64; prompt evacuation of the uterus in, 1095; renal decapsulation in, 32; treatment of, 830; treatment of puerperal, with nitroglycerin, 1002.
Eczema, treatment of, in infants and young children, 579.
Edema limited to arms, face, and hands, 872.
Edinburgh medical journals, consolidation of, 1038.
Egg poisoning, 534.
Electroanesthesia, 117.
Electrolysis in tic douloureaux and in spinal sclerosis, 703.
Elsberg, C. A., pneumothorax and posture; importance of the abdominal posture in operations on the pleura and lungs, 846.
Ely, Leonard W., report of nine cases of fracture of the carpal scaphoid, 766; report of three years' work at the Sea Breeze Hospital for the treatment of surgical tuberculosis in children, 383.
Embalming, bill against unauthorized, 611.
Embolism, the mechanism of pulmonary, 119; the surgical treatment of pulmonary, 271.
Embolus, post-operative pulmonary, 446.
Emphysema, pulmonary, operative treatment of, 945; pulmonary, surgical treatment of alveolar, 807; surgical, 30.
Empyema, recurring, 29.
Encephalitis, acute, in infants, 19.
Endocarditis, malignant septic, 967; malignant, without bruit, 113.
Endometritis, 184, 533; treatment of, by irrigation and drainage, 681; treatment of chronic, 520, 615.
Endothelioma in uterine polyp, 669.
Enterocolitis, mucomembranous, 954, 1098.
Epilepsia, 317.
Epilepsy, cardiac arrest as a cause of, 447; nitrogenous metabolism in, 702; operative treatment of, 447; the colony and bromide treatment of, 581; traumatic, 120.
Epileptiform attacks in diabetes mellitus, 801.
Epithelioma and carcinoma of the mucous membrane, treatment of, 567; a study of 400 cases of, 465; etiology of, 322; origin of, 287; the Roentgen ray treatment of, 112.
Erdmann, John F., renal and ureteral calculi complicating or simulating appendicitis, 427.
Erythrocythemia and cyanosis, 915.
Esmarch, death of, 402.
Esophagus, artificial intrapulmonary pressure; application to surgery of the, 1009; esophagoscopy in cancer of the, 158; strictures of, 786.
Ether anesthesia, 353; the dangerous effects of, and chloroform, 104.
Ethyl chloride narcoses, 32, 3000.
Eustachian tube, stricture of the, due to adhesions in the fossa of Rosenmuller, 217.
Examination expert arrested, 695.
Eye, injury to, by pieces of steel, 668; method of suturing the lateral recti to insure greater mobility of the stump after enucleation, 1001; tests for chauffeurs, 1037.
Eyelids, tongue, and jaw, synchronous movements of the, 30.
Eyestrain and functional neuroses, correlation of, 894; and moving pictures, 28; influence of, on tuberculosis, 1088.

F.

Fat, absorption in infants, 582.
Fauces, fenestration of the anterior, 279.
Featural surgery, 64.
Feces, precipitin reaction for, 281.
Fehling's solution, anomalous reactions with, 241.
Femur, fracture of the, in delivery, 77; Hodgen splint treatment of fractures of the, 78; treatment of fracture of the neck of the, 313; treatment of fractures of the, 78.
Fetal infection, prevention of, 920.
Fever, pernicious, remissions in, 1052; recurrent, pathology of, 1003.
Fibromyoma, symptomless, 1096; treatment of uterine, 1093.
Fibrosarcoma, periosteal, 1003.
Filariasis, unequal distribution of, in the tropics, 323.
Filter, oral, to be worn during operations, 448.
Finch, Edward B., urticaria, 301.
Finger tips, abnormal, 785.
Finsen treatment, 534.
Fire gongs to be removed from hospitals, 107.
Fischberg, M., lodge practice, 700.
Fischer, C. S., sources of error in gastric diagnosis, 851.
Fish food, a new, 407.
Fistula, anorectal, 85, 235.
Fitz, Prof., in honor of, 861; resignation of, 488.
Flowers that bloom in the spring—the, with variations and digressions, 394.
Floyd, Rolfe, examples of chronic productive inflammations in early life, 522.
Folsom fund of Harvard University, 527.
Fordham Hospital, 655.
Fowler's position, 182.
Fox, Prof., degree for, 1038.
Fractures, new ideas on, 665; of the radius with injury of the median nerve, 1079.
Franze, P. C., success and failure in Nauheim cures, 774.
Frèmont-Smith, F., early use of tuberculin by the non-febrile method, 949.
Fresh-air school, 189.
Freud's method of psychotherapy, 481.
Fridenberg, Percy, simple apparatus for aspiration and evacuation of the tympanic cavity after paracentesis, 419.
Friedman, G. A., obstruction of the duodenum by gallstones. Preoperative localization; operation; recovery, 565.
Frontal sinus, intranasal drainage of, 871.
Function, the chemical regulation of, 246.

G

Gall-bladder surgery, 738; the pathological, 283.
Gallstones, atresia of the common duct due to, 284; disease and surgery, 493; disease, symposium on, 34; obstruction of the duodenum by; operation; recovery, 565; pathogenesis of, 526; statistics desired, 488; the largest on record, 283.
Gangrene, carbolic, 144; of the foot, spontaneous, due to endarteritis, 592.
Ganglion, rôle of sphenopalatine (or Meckel's), in nasal headaches, 954.
Gas poisoning, direct transfusion of blood in, 232.
Gases, digestive, the origin of the, 582.
Gaston, Dr. J. M., appointment of, 906.
Gastric contents, distribution of hydrochloric acid in the, 195; diagnosis, sources of error in, 851; secretion, disturbances of, 898.
Gastritis, phlegmonous, 30; suppurative, 122.
Gastroenterostomy, physiological aspects of, 280.
Gauze pack, inconsistencies of the, 122.
Genitourinary operations, the preparatory and after-treatment of, 417.
German congress of internal medicine, 866; Hospital, new isolation building of, 527; Poliklinik, celebration, 863.
Germany, population in, 336.
Gibb, W. T., cardiac hydrothorax, 346.
Glandular fever, 494.
Glasses, reasons why opticians should not prescribe, 266.
Glycuronic acid, in diminished oxidation, 240.
Gnichtel, A. L., study of clinical cases by committees, 490.
Goelet, A. H., treatment of chronic endometritis, 615; treatment of endometritis by irrigation and drainage, 681.
Goiter, exophthalmic, diagnosis and treatment of, 532; exophthalmic, small doses of arsenic and bichloride of mercury in, 229; exophthalmic, surgical treatment, 874; exophthalmic, two cases of, 451.
Goldfarb, Samuel J., relapsing fever, with a report of two cases, 433.
Goldstein, L., a new adenoid curette, 884.
Goldstone, Karl H., the injurious habits and practices of childhood: their detection and correction, 1030.
Goldwater, S. S., the unfinished business of general hospitals, 978.
Gonococcus infection, unusual effects of, 408.
Gonorrhea in women, 367; vaccine treatment of, 493; vaccine and serum treatment of, in female children, 1052.
Gonorrheal infections, treatment with gonococcic vaccines, 874.

Goodall, Henry S., the relation of pleurisy to pulmonary tuberculosis, 1074.
Goodman, C., surgical treatment of alveolar pulmonary emphysema, 807.
Gordon, A., acute bulbar paralysis, with an unusual symptom, 349; integrity of stereognostic function and of all forms of sensation in a lesion of the left parietal lobe, 648; relation of accidents to functional nervous diseases and psychoses; medico-legal considerations, 54.
Gorgas, Colonel William C., method of the spread of yellow fever, 1061; sanitation of the Canal Zone, 259; President-elect, 1034.
Gout, the hydrochloric acid treatment of, 31.
Graef, C., report of fifty cases tested by the Calmette ophthalmoreaction for tuberculosis, 772.
Gratitude, professional, 1089.
Graves, W. W., clinical study of a case of brain tumor; operation; complete recovery, 841.
Green, Crawford R., instruction in hydrotherapy, 193.
Griffith, Frederic, a new fish food, 407.
Grip epidemics, 22.
Grocco's sign, 871.
Groff, Dr. C. A., appointment of, 906.
Gross, M., disturbances of gastric secretion, 898.
Guilfoy, William H., the death rate of the city of New York, as affected by the cosmopolitan character of its population, 132.
Gunshot wound of the abdomen, laparotomy, recovery, 160.
Gynecology and abdominal surgery, how much should the practitioner know? 514; progress in, 413.

H

Haig, Alexander, the organic factor in high blood pressure, 219.
Hallux valgus, treatment of, 286.
Hamlet, a psychological study of, 172.
Hancock, Frank H., a plea for the correction of uterine displacements, 396, 781.
Hand, the, as a therapeutic agent, 322; uninfected *vs.* disinfected, 448.
Harbin, W. P., report of three cases operated upon for large abdominal tumors, 935.
Harlem eye, ear, and throat infirmary, 906; new building for, 1038.
Harrington's solution in arthritis of the knee, 285.
Harvard Medical School, gifts to, 779.
Harvey Society election, 905; lecture, the fourth, 108; the fifth, 192; the sixth, 274; the seventh, 403; the eighth, 442; the ninth, 696; the tenth, 865.
Hay fever, the treatment of, 150.
Head trauma, with lacerations of cortical centers, 161.
Headache, 70; sugar, 535.
Hearn, a biography of Lafcadio, 487.
Heart and pericardium, surgery of the, 123; automatic rhythm of the, 113; clinical observations on absolutely irregular, 967; dilatation, acute and transitory, of, in an infant, 1045; disease, liver symptoms in, 1069; some new facts regarding, 390; diseases, physical diagnosis of, 627; estimating the power of the, 579; newer aspects in the pathology of the, 249; sound, the early diastolic, 624; spontaneous rupture of, 914; symposium on diseases of the, 249; teleradiography of the, 315.
Heat, extreme, in Australia, 151; the application of, in pelvic surgery by the Bock samovar, 536.
Hebrew charities, 233; closed, 23.
Hejira, the new, 189.
Hemoglobin and iron in blood of infants, 736.
Hemoglobinuria, paroxysmal, 965.
Hemoptysis, amylnitrite in, 822.
Hemorrhoids, bleeding, 269.
Henry, A. G., treatment of cancer, 181.
Hernia, incarcerated femoral containing a Fallopian tube, 500; operations for, in infancy, 946; the contents of irreducible inguinal, 157.
Herter lectures, the New York, 22.
Hip, unrecognized fractures of, 914.
Hip-joint disease, ambulatory treatment of, 322; report of thirty-one cases of congenital dislocation of, reduced by manipulation, 848; tuberculosis, amputation, 667.
Hirsch-Sprung's disease, operative treatment, 693.
Hodgkin's disease, pathology, diagnosis, and treatment of, 1056.
Hodgkins prize of the Smithsonian Institute, 316.
Hoffa, death of Dr., 67.
Homicide, the mental state preceding a, 360.
Hospital accommodations, insufficient public, 824; ambulance system, 795; benefits, 317; bequests to, 151, 234, 317, 487, 694, 695, 864, 995; City, changes in, 107; educational rôle of, 822; fare, 400; interneship, value of, 831; new maternity, 740; robbery in a, 317; ship under medical command, 65; ships, 991; staff, retirement of, 906; strict rules for, 1038; system of New York, 704; the London, 582; the unfinished business of general, 978.
Hospital Saturday and Sunday, 739.
Hotels, summer resort, 106.
Huber, John B., the winning fight against consumption, 973.
Hudson River State Hospital, psychopathic ward for, 611; to safeguard the, 486.
Huey, Arthur J., some notes on the etiology, prophylaxis, and therapeutics of laryngeal tuberculosis, 207, 333.
Hughes, appoint of Dr., 947.
Humerus, removal of the whole or a part of the, 285.
Hydatid disease, precipitin reaction in, 914.
Hydrobilirubin, extraintestinal origin of, 912.
Hydrocephalus, cerebellar symptoms in, 1051.
Hydrochloric acid, the oxychloraniline reaction for, 70.
Hydrogen, uses of peroxide of, 915.
Hydrophobia, prophylaxis of, 314.
Hydrostatic lung test, 905.
Hydrotherapy in pediatric practice, 503; instruction in, 92, 193.
Hydrothorax, cardiac, 346.
Hygiene, the new school, 986.
Hyoscine and scopolamine hydrobromide in refraction work, 784.
Hyperacidity, the surgical treatment of, 158.
Hyperemia and tuberculosis, passive pulmonary, 702; as a therapeutic measure, 625; Bier's, movement of tissue fluids in, 916; in the treatment of internal disease, 581.
Hyperphonia, treatment of, by the practitioner, 116.
Hyperpyrexia in children, 1051.
Hypnosis, operation under, 754.
Hysterectomy, 753.
Hysteria, 913.

I.

Ice supply, pollution of sources of, 778.
Illinois State Board examination, 823; State Board of Health, 107; State Medical Society elections, 907; occupational diseases in, 106; institutions, administration of, 487; sanatorium bill, the, 233; university of, commencement exercises, 1037.
Immigration statistics, 901.
Immunity in living tissues, 665.
Immunization by mouth, 410.
Inebriates, institution treatment for, 401.
Indiana medical colleges merged, 655.
